This Act was passed at the latter end of the century, when it should have been a law 60 years ago. Instead of being a simple measure repealing in a single sentence all and every kind of restriction upon mechanical traction it is a long-winded screed written in a spirit of minatory permissiveness, as though the House of Commons was not at all sure that even yet they were doing a right thing in sanctioning anything which would detract from the value of their favourite fetish, the horse. Throughout the Act ample scope is afforded to local and judicial authority to gratify personal idiosyncrasies and prejudices, and already there have been not a few cases of most unjudicial prejudice against automotor-vehicles displayed by magistrates and others.

At first sight the Act apparently encourages automobilism. As a matter of fact, while it permits the employment of light horseless vehicles, it discourages the use of heavy ones. Thus we are limited to a weight of 3 tons for the latter, and a maximum speed of five miles per hour.

These limits, there is some reason to think, were fixed for the purpose of rendering the Act inoperative. The Government took counsel with its engineering advisers, and it was told that it was impossible to build an automobile vehicle that would be powerful and strong enough to carry loads of 5 tons and upwards at reasonable speeds on a weight of 3 tons.

This belief is very prevalent among English engineers, and I have heard even respectable mechanical authorities say it cannot be done. Whether the Government purposely fixed this weight as a maximum in deference to the wishes of those who follow the cult of the horse, and who constitute (like the brewing interest) such a powerful majority in both Houses, for the purpose of rendering the Act nugatory, I am unable to say definitely. But my own conviction is that this is the reason of fixing upon a 3 tons' limit, and my object to-night is to show how we can if not drive a coach and horses, at any rate drive a heavy automobile vehicle through this Act of Parliament.

The Act has many objectionable features, one of which is that power to vary its provisions is entrusted to a State department. We have only to remember the unfortunate results to the shipping industry that have ensued as a consequence of allowing the Board of Trade to practically vary at its will the Merchant Shipping Act by Orders in Council to see what harm may and possibly will result from giving these extensive powers to the Local Government Board. The evil of this is that important alterations in executive details can be made in deference to the wishes of a sufficiently powerful but possibly hostile interest, and possibly also against the actual wish of Parliament. Another objectionable feature is that it gives very large powers to local authorities. For my own part, I think the less power local authorities are entrusted with the better, because local power invariably means the ascendency of local prejudice. Thus a county council, or other similar body, can practically, if so minded, wholly prevent automobilism within its jurisdiction. All it has to do is to build a weak bridge across a brook strong enough for light traffic and then issue a bye-law under the Act preventing the use of it by heavy automobiles on the ground that its use would be attended with danger to the public. It can thus stop access to the Queen's highway to any automobilist; the latter having no redress of any kind. Similarly a local authority can obtain power to absolutely prohibit the use of automotors, and in many towns and districts where the agricultural and horsey interests prevail, this power will undoubtedly be exercised. My objection to this devolution of authority to local bodies is that it puts power into the hands of men who are not always qualified to exercise judicial impartiality; with no appeal from their decision. For instance, can we suppose that a parish, town, or county council, the majority of whose members are either directly interested in the use, breeding, or sale of horses, or depending largely upon the patronage of those who constitute the local "hunt," would exercise strict judicial impartiality in the use of automobile vehicles, and in the interpretation of the law relating to them? I think not.

Still another objectionable feature of the Act is its harsh penal nature. Under the statutes relating to ordinary vehicles the most serious offence is met with a fine of £5, and minor offences with fines of 5*s*. to 20*s*. and upwards, but under the "broad-minded measure" referred to, any—even the most trivial—breach can be punished with a fine of £10. This is but another instance of the unjust discrimination against the users of automobile vehicles.

As regards taxation, too, we see the same injustice. It has for years been a dream with successive Chancellors of the Exchequer to impose a van and wheel tax. Many of you will remember some years ago that Sir W. Harcourt, or was it Mr. Goschen, proposed this imposition. You will also remember the howl of protest and indignation that went up from peers, tradesmen, and costers in denunciation of the proposal, which the Minister promptly and discreetly dropped. While, however, the tradesman's cart is still a sacred thing, not to be taxed by avaricious Chancellors, an automobile is, if used as an ordinary carriage and weighing over 2 tons, made to pay three guineas.

In another respect I think the Act faulty. We are allowed under it to haul one wagon, such wagon not weighing more than 1 ton. Now to answer the requirements of Liverpool it would be necessary to carry at least 5 tons on that wagon, and the heavy wagons at present in use, and which are employed to carry from 3 to 5 tons, weigh from 30 to 35 cwt. It would, I think, be difficult to design a cheap and useful wagon weighing much less than this. A 1-ton wagon or lorry is at best a light affair and not adapted for heavy loads.

The Act is, however, a small mercy, for which in these days of dilatory legislation we must be thankful, and a meed of thanks is due to those public men who, against a powerful opposition, succeeded in getting it through at all. Speaking generally, it must be confessed that the legislation affecting transport, whether by sea, by rail, by canal, or by automobile vehicles, has been narrow in its views and repressive in its tendencies, and has generally had the effect of placing the home trader at a disadvantage as compared with his foreign rival. I am afraid that the question of internal transport will ere long force itself upon the attention of Parliament. We see an increasing dependence upon foreign foodstuffs, the reason for which is the absence of means of cheap internal transport. We are also losing our hold upon not a few manufactures which we have hitherto regarded as peculiarly our own. Many reasons may be adduced for this—superior foreign technical education, in some cases superior means of production, but the principal one is the heavy cost of transporting the raw material from the outports to the interior and sending it back as the finished product. As I have said, we cannot expect much reduction in railway rates. We must develop our canals and remove every restriction upon automobilism.

Before proceeding further it will be as well to consider existing practice in handling heavy weight on ordinary roads.

The railway companies and the large firms of carriers employ a heavy description of van weighing from 30 to 35 cwt., and which costs new from £50 to £70. On this van they will place loads varying from 3 to 5 tons according to the nature of the route. From my inquiries I learn that as far as possible the loads are such as can be comfortably hauled by two rather than by three horses. A pair of horses might cost £80 to £100 in London, but the magnificent horses one sees in Liverpool could not, I am told, be purchased for much less than £60 to £70 apiece, and will cost at least £1 per week each for maintenance, &c. We can then say that a horse-drawn van capable of carrying about 3 tons on the flat, its weight will be—

Van	1·5 tons.	Cost.. ..	£70
Two horses at 12 cwt. (each)	1·2 „	„	120
Total weight	2·7 tons.	Total cost	£190

I give these figures as to cost with all reserve, as such information is regarded as secret by the railway companies, why I do not know.

On a very good road, practically level throughout, such a van could haul a load of 4 to 5 tons at a speed not exceeding 2 miles per hour. On a gradient, such as is common enough in Liverpool, of 1 in 20, the load would have to be halved and three times the number of horses employed. It will be advisable to devote a few words as to the actual power of a horse. Very much has been said and written about the ability of a horse to exert at times a pull many times in excess of its normal pull. This power is, however, spasmodic, and, although useful in starting a heavy load, does not suffice to haul that load continuously up an incline. Neither is this power exercised very intelligently. The horse, unlike a steam-engine, does not increase its pull with an increase of speed. I am not disposed to unduly depreciate the horse, which will always be a useful motor for many purposes. Heavy traction is, however, the thing the horse is least adapted for.

Let us now consider what actual power is required to haul any given vehicle on any given road at any given speed, and overcoming a given resistance. Many empirical rules have been given for this, but the power required for any vehicle admits of very accurate determination when the data are known.

Let H.P. be the actual power required;
W the total weight to be moved in tons;
V the speed in miles per hour;
r the resistance per ton of vehicle;
a the angle of grade;

then—

$$\text{H.P.} = (r \cos a \pm 2240 \sin a)\ \text{W.V.}/375.$$

If, instead of having the angle of grade given, we have the gradient expressed as 1 in m, then we may write—

$$\text{H.P.} = \left(r \pm \frac{2{,}240}{m}\right) . \frac{\text{W.V.}}{375}$$

As regards the resistance, this may be made to include the axle-friction. The resistance on good macadam roads would appear to be from 40 to 60 lbs. per ton; but in order to ensure ample power on bad roads, and also to form a useful basis of comparison, I have taken a standard resistance of 100 lbs. per ton. On the excellent Liverpool streets I should say the resistance does not exceed 50 lbs. per ton.

As regards the H.P., this is that required on the brake, and the quantity found would, in the case of steam-engines, have to be increased by 20 per cent. in order to obtain the H.P. as indicated, or as that actually developed by the steam. The actual power required to haul a van weighing, with its load, 4½ tons 2½ miles per hour up a gradient of 1 in 17, such as is not uncommon in Liverpool, against a mean resistance of 100 lbs. per ton, is 6·9 B.H.P. nearly. Now, here we can elucidate a rather interesting point.

It is a matter of surprise and incredulity with many people that such large mechanical horse-powers are required as compared with the actual animal power. Really the explanation is simple. When Watt fixed the H.P. at 33,000 foot-lbs. per minute, he obtained his data from the exceptionally heavy and powerful horses used in breweries, but their best average work was only 22,000 foot-lbs. per minute, and Watt increased this by 50 per cent., so that our engineers' H.P. is 50 per cent. higher than the actual. If now we deduct 50 per cent. from the amount found in this case, we have 2·45 actual animal H.P. as that necessary; in other words, to haul this load three powerful horses would be required. On the flat this load would require 3 B.H.P., or 1½ actual animal power; in practice two horses would be employed.

In order to haul a vehicle such as I propose, weighing in working order 11 tons, at a speed of five miles per hour on the level, 14·6 B.H.P. would be required, or eight horses, assuming for the moment that these could exert the same pull at this speed as at lower speed. As a matter of fact, the pull of a horse varies inversely as the speed, and according to the data given by Trautwine the pull of a horse at five miles is about 50 lbs., or one-fifth of that at one mile. Without labouring this point, it will be seen that it is a commercial impossibility to haul by animal power a weight of 11 tons on a good road at five miles per hour, needless to say, hauling this weight up a 10 per cent. grade at half that speed is utterly out of the question. One, indeed, only has to see the number of horses required to haul a light field gun and its ammunition wagon at a respectable speed to see how impossible it is to deal with heavy weights at even comparatively low speeds with horses. If anyone will apply the formula given above to any number of cases and then apply, what I lack, the knowledge of the commercial side of the question, it will, I think, be found that the present usual loads—3 to 5 tons on the flat and 2 tons on a gradient, hauled by three horses at 2 miles per hour, about represents the economical limit of horse traction. On the other hand, for loads (total) not exceeding ·75 ton the horse is perhaps, in all round respects, superior to any mechanical motor at present prices. The actual economy in any given case can be, however, very accurately determined by Kelvin's law of economy.*

We will now pass on to consider briefly the features of the most recent examples of heavy automobile vehicles. Below I give the particulars relating to the Scotte and De Dion et Bouton vehicles, known officially as Nos. 1 and 14 respectively. These vehicles, with others, took part in Les Poids Lourds Competition, held last year at Versailles, and which I was permitted to attend. Both these vehicles are driven by steam motors and both have been eminently successful, and have answered every purpose for which they were designed:—

	Scotte, No. 1.		De Dion et Bouton, No. 14.	
	lbs.	tons.	lbs.	tons.
Weight of vehicle, empty.. ..	9,240	= 4·125	9,438	= 4·213
„ on fore axle	5,632		4,312

Revs. per minute	400	600
H.P.	14	25
Consumpt of coke per hour per square feet of grate	67·6 lbs.	30·6 lbs.
Consumpt of water evaporated per pound of coke	5·3 lbs.	3·1 lbs.
Consumpt of coke per ton mile of total weight	2·2 lbs.	1·1 lbs.

Daily Expenses (Full Load).

	Scotte, No. 1.	De Dion et Bouton, No. 14.
Daily distance (miles)	68·2	89·9
Tons	6·05	5·87
Ton miles	412·6	528
Daily expenses, interest (6%), repayment of capital (15%), maintenance, repairs, wages, fuel, water, stores, and all expenses	2·04*l.*	1·98*l.*
Effective ton miles	68·2 × 1·2 tons = 80·8	90 × 1·12 tons = 101·06
Freight per ton mile	$\frac{2·04}{80·8}$ 6·048*d.*	$\frac{1·98}{101·06}$ 4·704*d.*

The figures are interesting and instructive. You will observe that what shipping people would term the dead weight capacity is but 18·6 and 18·2 per cent. respectively, while the wagon accounts for 65 and 69 per cent. of the total weight. In horse vans, the van and horses will weigh, perhaps, not less than 50 per cent. of the gross. Judging from the practice which obtains in naval architecture, these figures are very poor, and I suggest they can be much improved on. You will also notice that there is not very much difference in the leading features of the design. Although the De Dion vehicle has nearly 80 per cent. more H.P., the weight of the motor is but very little more; on the other hand, the pressure is higher, and the revs. also. We thus see the advantage of employing high pressures and high revs. You will also notice that the consumption of coke and water is much less in the case of the De Dion vehicle, and at first sight one can hardly credit the great difference. The figures are, however, official, and have been since checked. The consumpt of coke per ton mile is just one-half in the case of the De Dion vehicle. I do not profess to be able to explain these discrepancies, but they are, I think, worth analysing. They seem to me to indicate the necessity of very careful design in the engines and boilers, and mechanism generally. The De Dion had very good and copious lubrication, and this, I think, is one factor.

As regards the expense attached to running these vehicles, you will see that the cost per ton mile is in the case of the Scotte nearly twice that allowed in the estimate prepared by your Association for the forthcoming trials in May next, while in the case of the De Dion vehicle the cost is 51 per cent. higher. We must, however, remember that these vehicles were not built for the carriage of very heavy goods. They are, in fact, steam omnibuses, and hence there is a good deal of space unused. Had these vehicles been built as steam lorries their ton miles would have been very much increased and the cost per ton mile much less. These examples are, however, most useful to the designer. Among other things that they demonstrate is the practicability of employing high-steam and fast-running engines with absolute certainty and safety.

Another point about these vehicles. We have been assured that vehicles weighing much over 5 tons will rapidly destroy the roads. Now, these French vehicles are not new, they have done excellent service in all weathers and on every kind of road; but I have not seen in the French Press a single complaint about them damaging the roads, and on inquiry I find that although the performances of these vehicles have been most attentively watched, and trials have been carried out by the officers of that excellent branch of the French public service, Les Ponts et Chaussées, yet beyond recommending the adoption of these vehicles nothing has been said about the roads. I mention this as it is very necessary that local authorities should not allow themselves to be biassed or prejudiced in the matter, and I would suggest that the Self-Propelled Traffic Association should obtain the French Government reports on the subject so that the most authentic information should be at the disposal of those interested. It must be borne in mind that the French roads, being laid out and constructed largely for military eventualities, are much superior, as a rule, to ours. In France and in other Continental countries the object in view is the transport of heavy siege guns rather than farmers' wagons. Before quitting the subject of these French vehicles I think we may congratulate the distinguished French engineers MM. Scotte, De Dion, Bouton, Le Blant, and others upon whom the mantle of Gurney, Dance, and Hancock has apparently fallen.

Part II.

In designing an automobile road carriage for any particular purpose the principal considerations are the weight to be moved and the speed to be attained. As regards the material to be employed in construction, the nature of the motive power, the kind of fuel, &c., these will depend partly upon the foregoing and also upon local considerations. The problem we have to solve to-night is to sketch out the leading features of the design of an automobile wagon which shall carry a cargo of not less than 7 tons, which shall maintain a speed of five miles on the flat on ordinary good macadam roads, and which shall climb a 10 per cent. gradient on the same description of road at a speed of not less than 2½ miles per hour. As you all know, the maximum weight of vehicle allowed under the Act is 3 tons. We will assume the following weights:—

Vehicle, empty	6,720 lbs.	= 3 tons.
Cargo	15,680 "	= 7 "
Water	1,000 "	= 0·82 ton.
Coke	500 "	
1 man, 1 boy, tools, and oil	350 "	
Total	24,250 lbs.	= 10·82 tons.

Or, say, 11 tons in full loaded working order.

Motive Power.—I suppose the use of steam as a motive power, as in the present state of our knowledge no other form of energy possesses the preponderating advantages that steam does for heavy work. Although for lighter service oil-engines and storage cells are efficiently employed. Oil-engines using preferably what is known as "heavy oil" are being largely used for the purposes of marine propulsion, and are made to develop as much as 90 H.P. for yachts and trawlers, in both of which unskilled, or perhaps it would be better to say unprofessional, labour is so largely employed. Oil-motors are a convenient and inexpensive source of power, but for the purpose under discussion they are not suitable, because their use involves various trains of gearing in order to obtain variations in speed. Being unidirection, a reverse motion means the use of more gearing, while at small loads the motors are uneconomical, and, lastly, they do not permit that variation in speed and power that steam-engines do.

Steam for heavy road traction, as also for railway traction, and, to coin a phrase, water traction, is beyond question the only suitable source of energy known at present.

Dealing now with the power necessary to propel our proposed vehicle, we apply the formula mentioned before, and in order that our automobile shall be able to take any ordinary road we assume a resistance per ton of 150 lbs. This is about three times that which obtains in the Liverpool streets. Running out the simple calculation, we find that to propel this vehicle at five miles per hour on the flat requires 22 B.H.P., while to propel it on a 10 per cent. gradient at half this speed requires 27·2 B.H.P. Allowing 20 per cent. for loss in internal friction and in transmission, these figures become 26½ and 34 I.H.P. respectively. That is to say, that we must have a boiler and engine that will give off not less than 35 I.H.P. continuously, if required.

Here I would draw your attention to our formula:—

$$\text{H.P.} = (r \cos a \pm 2240 \sin a)\ \text{W.V.} / 375.$$

You will observe that the power required varies directly as the resistance, as the weight, and as the speed. In other words, the power follows a "straight line law." This is, as compared with the law that obtains in steamship performance, charmingly simple. In the case of steamships the power varies according to a law which has not yet been accurately determined.

Since, as we have seen, the power required in an automobile vehicle varies as the weight and speed, we may say, as a rule to be carried in the memory, that on ordinary roads on the flat, where R=50 lbs. usually, ·133 H.P. are required to propel a vehicle weighing 1 ton at a speed of one mile per hour. A better rule, and one which takes into account the worst kind of roads, is to allow ·4 H.P. per ton per mile.

The next point is to decide upon the material of construction. Limited as we are to a weight not exceeding 3 tons, and desirous as we are, on the other hand, of utilising this to the utmost advantage, we are bound to use those metals which combine strength with lightness. Now, the metal which so far combines these two qualities in a greater degree than any other is that alloy known as nickel steel.

Nickel Steel.—For the following particulars I am indebted largely to the paper by Professor Biles, M.I.N.A., read at the last summer meeting of the Institute of Civil Engineers.

Nickel steel is, as its name implies, a combination of steel and nickel, the latter being about 3½ per cent. It is adopted by our Admiralty for torpedo-boats, and this particular kind has a T. S. of 37 to 43 tons, with a 10 to 15 per cent. extension in 8 inches. Ordinary mild steel plates have a T. S. of 28 to 30 tons; about 14 to 15 tons elastic, and with an extension in 8 inches of 20 per cent.

Mr. Beardmore, who has been mainly instrumental in introducing this alloy, recommends a nickel steel having a T. S. of 52 tons ultimate, 28 tons elastic, and 13½ tons elongation in 8 inches. In other words, such material is about twice as strong as the former.

It is, however, at present somewhat dear, but the price will, of course, come down as the demand and manufacture increase. For automobile vehicle-work, whether these vehicles be light or heavy, nickel steel offers some distinct advantages. While obtaining the same strength in the body or framing, we can put the saving in weight into the machinery and make a more satisfactory job.

In order to assist designers I give the following table which gives the mean result of a large number of tests:—

Mild Steel Annealed.

Tensile	63,000 lbs.
Elastic limit	30,000 „
Elongation	28 per cent.
Contraction	80 „

Medium Nickel Steel Annealed.

Tensile	85,000 lbs.
Elastic limit	45,000 „
Elongation	25 per cent.
Contraction	80 „

According to Professor Biles—whom we may regard as a distinguished authority on naval construction, and who is well known in Liverpool as the designer of two of the fastest Atlantic liners—this allows a reduction of one half in scantlings subjected to tensional stresses, or, allowing for butt connections, a reduction of 33⅓ per cent. in weight. In any automotor vehicle the stresses are naturally very severe, and hence a good margin of strength must be provided in order to guard against any deformation. If we employ mild steel, we should for tension stresses (following Unwin) not permit a higher working stress than 6,600 lbs., which is almost one-fifth of the elastic. Taking the elastic strength of nickel steel at 28 tons, we get 12,500 lbs. as the safe working stress. As a matter of Lloyd's or Board of Trade inspection this, no doubt, would be considered as providing a prudent margin, but we might go as high as 20,000 lbs. and still be within the elastic limit.

For structures such as ships at sea, bridges, railway engines, machines, &c., where any failure of material might entail personal injury, a large factor of safety is not only desirable but absolutely necessary, but for the framing of a vehicle moving at a low speed no such precaution is necessary, and hence for the framing, &c., a factor of safety much lower than would be used for the foregoing structures may be safely employed.

(To be continued.)

PROCEEDINGS OF TECHNICAL SOCIETIES.

Mechanical Features of Electric Traction.*

(Continued from p. 158.)

EXPERIENCE demonstrated that the only effective plan was to attach the motors to an independent truck-frame, and to have all the mechanism of the car entirely independent of the car body. For this purpose an independent truck was introduced, consisting of pedestals secured by centre bars; upon the pedestals the motors were suspended by cross-bars connecting the side frames of the truck together. While these trucks supported the motors independently of the car body, they did not properly support the car body itself, which had increased in length and width. The increased length and width of the electric car, together with the increased speed at which it ran, rendered a stronger and longer truck necessary. At first the old street-car pedestals were fastened to a separate pair of sills. The axle-boxes still played up and down in these pedestals to the full extent of the motion of the car body. This device proved insufficient. The next step in advance was to secure the pedestals carrying the axle-boxes to side frames, which carried the springs supporting the car body. This construction, however, allowed excessive swaying of the car body, owing to the fact of the connection between the wheels and the body not being sufficiently rigid. Moreover, no provision had been made for easily removing the wheels, which required the truck to be practically taken to pieces. The brakes were hung to the upper chord of the truck, the effect of which was that, when the springs were compressed, the brake shoes dropped lower on the wheels, changing the distance between the shoe and the wheel.

The introduction of mechanical motors, occupying so little room that a capacity of 50 or 60 H.P. can readily be placed in the space allowed by the truck, has led to a large increase in the weight of the car body, and a consequent lengthening of the wheel-base. The modern electric-car bodies carried on four wheels are seldom shorter than 18 feet over the end panels, and sometimes reach 22 feet length, exclusive of the platforms, while the whole length of the car over the platforms is from 30 to 32 feet. This increase of nearly 25 per cent. in the length and more than 25 per cent. in the weight of the bodies has been accompanied by an increase of only about 20 per cent. in the wheel-base of the trucks. As a result, a long and rigid spring-base is an absolute necessity for a modern electric truck. Without this the whole stress of carrying both the dead weight of the car and platforms and the fluctuating weight of the load would fall on the car sill and body, and the motion of the car would continually wrench and strain its framing. In the conditions met with in street service the wheel base cannot be lengthened much over 7 or 7½ feet; and on this account a long spring base must serve the purpose of an increased wheel base for the long cars now employed. To obtain easy riding it is necessary that all the springs should be sufficiently light to obviate vertical motion in the car body; consequently these light springs, in order to prevent excessive motion of the ends of the car, must be carried out just as far apart as it would be necessary to carry the wheels if the old horse-car arrangement were adopted for the modern long-car bodies.

To secure the necessary rigidity of the long side frames, and at the same time keep their weight within reasonable limits, different plans have been adopted. In earlier designs it was attempted to overcome the difficulty by casting the pedestal and overhang in one piece, and lengthening the joint between these castings and the bars. Another method consisted in trussing the overhang with straining rods running over the tops of the pedestals, and provided with turnbuckles for taking up the strain as the overhang worked down; but turnbuckles slack off, and the bolted joints wear loose, and a continual wear and rattle was the result. Some makers constructed the side frames of the truck in one piece, by bolting heavy centre-bars to the pedestals. Others again forged the side frame of the truck, and welded the whole together into one piece. But these designs have not proved sufficiently strong to support properly the permanent pressure upon the ends of the overhang, when the overhang is carried out to the length of the modern car body.

The demand for this special class of work brought out a host of devices, of which ten years' experience has sifted the useful from the useless; and it may be fairly stated that the chief principles

* Paper read at the Institution of Mechanical Engineers by MR. PHILIP DAWSON.

involved in the design of a thoroughly good motor-truck, fulfilling all or most of the conditions imposed by electric traction, have now been fully recognised, with the result that the electric motor-truck has been matured to a standard form. Truck building has become an independent business in America, although many car works still make some form of truck for themselves. Rigid frames had been employed in trucks for cars driven by gas, steam, compressed air, or cable grip; but in all of these the conditions are entirely different from those in electric motor-cars. This experience was dearly bought by some of the earlier electric tramways, as was testified by many a scrap-heap composed of trucks which, after running but a few miles, had to be discarded.

The quality of the motor-trucks may mean the success or failure of an electric tramway; and to secure a good truck is quite as indispensable as to use a well-constructed and efficient motor. A motor-truck comprises many parts, the most important of which are the side frames, springs, wheels, axles, boxes, bearings, motor bearings and suspension, sand boxes, brakes, and safety appliances. The following are the essential conditions which must be fulfilled by a truck in order that it may be suitable for electric traction:—

1. The truck must be as light as possible, consistently with rigidity and strength.

2. It must be thoroughly braced, so as to keep it stiff and square without having to depend in any way on the car body. The strains on a motor car in rounding curves, and when passing a change of gradient, are extremely severe: much more so than with horse-cars, where the horses pull the car round on curves, and go slower at a change of gradient.

3. The journal-boxes must be self-lubricating, must require but little attention, and must be dust-proof.

4. The brake action must be simple, effective, and easily adjustable; and the brake shoes must admit of being replaced at a moment's notice, and must be mounted in such a way as not to be influenced by the vertical motion of the car.

5. The truck must be constructed in such a manner as to render access easy to all parts; and to admit of motors, wheels and axles, journal-boxes, brake gear, and other parts being easily removed, without having to dismember the truck. Cross strains on bolts should be avoided as much as possible.

6. The car body must be attached to the truck in such a manner as to be readily removed on loosening a few bolts.

7. Springs must be arranged so as to render the running of the car as smooth when empty as when fully loaded, and to prevent the pitching and rolling motion to which street cars are so liable on sharp curves and rough roads. This is a highly important point, not only for the comfort of the passengers, but also to prevent rapid deterioration of the car wiring and car bodies; deterioration of the wiring is likely to cause grave results to the motors by producing short circuits.

8. An appropriate choice of wheels is most important.

There are three different kinds of trucks: the rigid four-wheel, the radial six-wheel, and the four-wheel bogie for eight-wheel cars. Of these three, however, only the first and third are generally used, the radial truck not having given the satisfactory results which were expected.

Four-wheel Truck.—In the rigid four-wheel truck, where the wheel base is naturally restricted, it is of the greatest importance to have an arrangement whereby the car body is supported as far outside the wheel base as possible, and to diminish as much as may be, by the judicious use of springs, the destructive effect of jolting, both upon the car body and upon the motor equipment. The best modern truck, which has been employed on all the latest and best-equipped British and colonial tramways, is the "Peckham," of which models are exhibited. It has been adopted by Bristol, Dublin, Guernsey, Clontarf, Coventry, Isle of Man, North Staffordshire, Dover, Leeds, Birmingham, Brisbane, Sydney, and other places, and in all cases has given the utmost satisfaction. The support selected as the model for a truck frame is the standard cantilever bridge truss, which experience in bridge-building has shown to be the strongest form of construction. This truss principle has been closely followed in the construction of the Peckham truck; and while various modifications in detail have been made to adapt trucks to the various conditions occurring in street tramway practice, the characteristic bridge form of truss has been strictly adhered to in all of them. The cantilever truck has now come to be regarded as the standard for the best work in the United States, inasmuch as 15,000 are now in use in that country.

As the length of the car body grows greater, the difficulty increases of supporting it properly at the ends without increasing the height of the car platform above the ground. The resistance offered by any truss to bending varies directly as the cube of its depth. If, therefore, the car platform were raised high enough above the street level, it would be an easy matter to support the sills of any car effectually so that it should be impossible for them to droop at the ends under heavy loads. It is an entirely different thing, however, so to support them when the height from the rail to the lower edge of the sill is limited, as it must be in street tramways. Beyond 27 inches, or at most 30 inches, every inch that the car platform is raised above the level of the street makes it so much the more difficult for ingress and egress. This is, therefore, practically the limit in height to which the car body used for city service can be raised. This problem has been solved by the use of extension rods in a way never before applied in street tramways. A second bridge truss is constructed by employing the extension rod as a lower member, and the car sill as an upper member; and this truss is supported flexibly upon the main truck truss. The truss extension rods, instead of terminating, as heretofore, at the extremity of the truck frame, are carried below and around its lower member, and are stayed to the car sill by bolts passing through the truck pedestals and end springs. The angle of the truss extension rods has not been changed in any way to secure a longer support; but as they are dropped bodily lower, they give a wider base of support to the car body than would otherwise be possible. By this method it has been found practicable to carry upon single trucks, with a wheel base of only 7 feet, cars as long as 35 feet.

Other important improvements include the flexible gear, which is so constructed that it allows the cantilever extension truss to be built in sections: so that the portion under the journal boxes can be removed, when necessary, for taking out the wheels and axles, but when in place it makes a continuous truss. This gear also allows of introducing in its upper portion coil springs for supporting the truck frames flexibly upon the journal boxes, thereby relieving the truck frames as well as the car body from the rigid metal contact with the rail, and also relieving the rail from the hammer blow which would attend a rigid connection between the rail and the car body.

Swivel Truck.—The rapid growth of inter-urban lines, upon which the tendency is to use long cars, and the desire on many tramways to use long cars for city work, have resulted in the swivel truck. This is the result not only of railway experience, but also of many years' experience of electric tramway needs. A truck so constructed runs exceedingly easy, the weight being doubly-cushioned by the two elliptical springs and spiral springs over each axle-box. The brake gear is simple, and the shoes are applied with a powerful leverage. The centre of gravity of the trucks has been brought down as low as possible; with cars having straight sides, the body of the car need not be more than 27½ inches above the rail. The wheel base has been kept short and the space between the axles kept clear, so that it is possible to mount two motors on the truck without difficulty. The arrangement of the springs on the trucks renders it possible to remove the bolster and elliptic springs quickly and easily whenever it becomes necessary to examine and overhaul the motors. When this has to be done, the car body is simply jacked up with the bolster and the truck frame can then be run out from under the car. The rivets used in the construction of all these trucks are driven in hot by means of pneumatic riveters under 30 tons pressure.

Motors.—In the early days the motors were all used with double-reduction gearing, with consequent great waste of power in a double transformation of the high armature speed to the low speed of the car axles, an efficiency of 60 per cent. being rarely obtained. At present, good design, workmanship, and materials have brought about such a change for the better that under most conditions an efficiency of 80 per cent. is attained, which remains constant with widely varying loads. When the application of electricity for propelling street cars was first practically attempted, it was endeavoured to apply the existing stationary motor to the existing running gear. The motor and axle were connected by means of belts, sprocket chains, friction clutches, and other mechanical devices, all of which, with few exceptions, have now been abandoned on account of the great expense of maintenance and their low efficiency. Double-reduction spur gearing was first introduced on the experimental line at Woonsocket, Rhode Island, which was jointly equipped in 1886 by the Thomson-Houston and Bentley-Knight Companies; and the advantages of a specially-constructed and self-contained motor-truck were there demonstrated. The high speed and comparatively cumbersome construction of motors at that time necessitated a double reduction in gear between armature and axle, each reduction being about 9 to 1. Thus an armature speed of about 1,500 revs.

per minute gave a car speed of about 15 miles per hour. The later makes of double-reduction motors, of which a great many have been employed both in the United States and in Europe, have done excellent work; but more recent and keener competition in electric traction has resulted in more advanced designs being developed.

The electric motor having demonstrated its ability to do the required work, the next problem was so to improve it as to reduce the working expenses as low as possible. This was partially effected by improving the design of the double-reduction motor, and to a much greater extent by the introduction of single-reduction gearing. The success of single reduction stimulated still further improvement in design; and motors mounted direct upon the driven axles and devoid of all gearing were developed. These, however, have not yet come into practical use for street cars on account of their increased weight and also of their rapid deterioration owing to the absence of any spring support, in consequence of which the motors receive all the shocks due to the comparatively rough tramway lines. The increased weight and rapid deterioration, and consequent increase in original cost and maintenance, have prevented their competing on even terms with improved single-reduction motors.

(*To be continued.*)

Automobilism on Roads.*

There are some millions sterling thrown away every year in the United Kingdom, as a result of insufficient expenditure on roads and means of transport. The fact that there are over a thousand millions sterling profitably invested in the railways of the kingdom is alone a proof of the national importance of the best means of transport of men and materials. We want not only more transport facilities but we want vast improvements in our existing ways of conveyance.

In another place I have said that "with the exception of land and ruins there are few material things of value to man which do not derive that value, in part at least, from transport from their original position." This may seem to be a well worn truism, but it is necessary to remember it when it is urged that cheap means of transit is one of the most important of all the subjects occupying engineers to-day, and one which offers, as it has always done, one of the most profitable sources of investment. It is not generally known that to-day it costs more to send a ton of goods by rail between some places in this country than it cost formerly to send it by horses on the common roads, but everyone does know that the Post Office finds it cheaper to send its parcels by road than to pay the rates demanded by the railway companies for that traffic. The cost of haulage by rail is very small, but the terminal cost and cost of the railway establishments as vast machines, are so heavy that the cheapness of railway transit in many cases disappears.

The requirements under the many Acts for the regulation of railways have, in this country, done much to bring this about; and while for long distances goods are conveyed at cheap rates, the short distance charges are necessarily heavy.

The average cost of transport to-day of goods between Liverpool and Manchester, a distance of 35 miles, is 9*s.* 6*d.* per ton. At the present cost of horse keep it could be done for about 8*s.* 6*d.* by horse, and by traction engines it can be done for from 1*d.* to 1·25*d.* per ton mile, or from 2*s.* 11*d.* to 3*s.* 6*d.* the whole distance to destination per ton at a good profit. The quantities to be conveyed, however, are so enormous, at least 15,000 tons per week, that the common roads would be cut to pieces with a quarter of it in a month. This is only one of many lines of communication where greater facilities are required, facilities which cannot be afforded by main line railways at present constructed and equipped.

The great requirement is a means of transport which will carry and deliver goods at a charge which shall bear some relation to the cost of haulage. There are hundreds of lines of communication which are at present almost without means of transport, but which may be served by railways and tramways constructed under the now very popular Light Railways Act, or by mechanical road vehicles. But with all that can be done by railways or tramways, there are the millions of tons of passengers and goods to be provided for between railway stations and destinations. We call this a mechanical age, and yet we are to-day as dependent on the horse and the common road wagon for the delivery to us of the goods brought from any part of the country as were our forefathers.

We pride ourselves on our road-constructing ability and apparatus, and yet our roads are no better than some of those of the Roman of a thousand years ago, and in our towns we admit this by the construction of tramways which are metallic admissions of the badness or insufficiency of our ordinary roads and pavements. These tramways and their cars we permit in our streets to the detriment of every other form of street vehicle, simply because the tractive resistance on a smooth hard road is less than on a rough road. We find that two horses can haul 42 passengers on a tramway instead of 26 in an omnibus, and so we allow our street traffic to be crippled by the hard-and-fast direction of movement of the heavy cars on these street railways. We put down grooved rails that wrench our carriage-wheels off, and twist our spines, and cut our rubber tyres to pieces. These palliations of bad roads we tolerate rather than make good roads and suitable vehicles to run on them. We are converting our streets into badly managed railways, with level crossings everywhere, and on which railway cars and common road vehicles struggle for supremacy, and horses struggle to keep a footing.

A visit to many of the London tramway and omnibus centres and starting places shows that we are rapidly reaching a density of traffic impossible to contend with, if the streets are to be anything more than lines of free railways, on which every car and omnibus and coal-wagon driver is traffic manager. In most provincial towns this sort of thing has not been reached, but there are several in which it is already obvious, as it is in London, that a large part of all the passenger traffic must be diverted from the streets to railways proper. Nothing but the short distance passenger accommodation must be allowed in the streets, either by tramcar or omnibus. As early as possible motor-cabs and omnibuses must displace horses, so as to save the space now occupied by them, avoid the spreading all over the streets of that which renders them dirty and unhealthy, and avoid the pounding of pieces of the wood, asphalte, and other of the best pavings, with the 3 cwt. hammers of iron-shod horses' feet. More suburban service railways are inevitable, as the population increases, and a big question arises in the selection or even discovery of the best and least objectionable form of railway.

The new deep underground lines will in London do a good deal to meet the increase in traffic in some ways, but they will develop traffic of their own, which for the busy parts of the day will detract from their powers as relief lines for existing excessive street traffic. Extended overground relief is possible in only a few places and directions, and in London these will be all required to relieve the crush which at present characterises such outlets to suburban homes as Ludgate Hill, Liverpool Street, Broad Street, London Bridge, Waterloo, and some of the metropolitan stations.

The city and suburban passenger traffic presents a problem which will occupy engineers and capitalists some time; but it is essential now that the whole subject should be dealt with comprehensively, and not a series of isolated schemes. When all this is done, the distribution of merchandise across towns and suburbs remains. If it is so difficult to provide for the transport of freight which takes itself to and from the trains, how much more difficult is the problem of cheap and expeditious transit of goods, which already employs about 3,000 horses hauling vans and carts of different kinds in London alone!

One of the first necessities is the provision of the best possible of street and road surfaces. At the outset of this problem we are confronted with the difficulty of providing equally for ordinary light traffic with not more than about a ton per axle, and for that up to as much as 2 tons per wheel. The latter must be provided for, and hence the lighter vehicles must accommodate themselves to the best surface obtainable which will withstand the wear of the heavy traffic. Fortunately, the light vehicles can be more readily made to accommodate themselves to the roads than the roads can to withstand uses of the heavy horses and vehicles, so that expediency brings back the problem to one of improvement upon our existing methods of wagon construction and maintenance of roads.

To some of these improvements I may refer briefly. They consist in—(1) Better and more durable surface, well supported on a good foundation. (2) Better methods of maintenance and repairs; and by this I mean constant attention to, and repair of, defects as they appear, just as on a good railway watchful care is bestowed by an ample and well-drilled service of men on every inch of the road. (3) The improvement everywhere of the gradients all over the country, by minimising them to the greatest possible extent.

Before dealing with each of these necessary improvements, it must be pointed out that I am assuming the existing type of vehicles to be

* Excerpt from the inaugural address delivered by Mr. Worby Beaumont, M.I.C.E., M.I.M.E., &c., before the Society of Engineers, London, on February 7th.

more or less permanent, or, at all events, persistent to so great an extent that the roads must be able to carry them. There is, however, I think, no doubt that the time is rapidly approaching when the load per axle on all heavy vehicles will be so far reduced by increased number of wheels per vehicle, that tyres of some yielding but good wearing material will be used for all purposes, and that we shall cease to use our roads and their materials as though they were the beds of mortar mills, traversed continually by 2-ton steel-shod edge-runners. We put minerals into the pans of edge-runner mills to get them ground to powder, and expect that this shall happen at a considerable rate of crushed output. We do just the same thing with the metal on our roads, and hope the same results will not follow; but they do, and so long as we construct roads as we do now, and run heavily-loaded iron-tyred wheels over them as we do, we shall continue to waste millions per annum in road renewals and in horse food and horse flesh.

Assuming, however, that the improvements in vehicles do not occur rapidly, the first and second of the road improvements I have mentioned render it absolutely necessary, in the first place, that the almost inconceivable folly of the practice of making expensive roads and road-beds one week and tearing them up the next, for more pipes and wires or repairs, shall be given up.

We live in an age in which people are every day making more and more use of artificial aids to comfort, and public supply and distribution of necessities. We get heat, light, fuel, and water supplied us by buried conveyors, and buried conveyors take away our sewage and drainage. We receive and send telegraph and telephone messages by buried conveyors, and we send packages of letters through buried air-pipes. All these conveyors we put under our costly street pavements, and generally act as though street and road surfaces were like pie-crusts, the usefulness of which only becomes obvious when they are broken up. The cost of this burial of all the conveyors, the cost of the breaking up of the roads for new burials and renewals, the cost of remaking the roads even in the imperfect way in which it is accomplished, and the time lost to hundreds of thousands of travellers and trades are so great per year that to state the truth would appear like gross exaggeration, and yet in the whole of London there are only a few miles of subways by which the waste is prevented. Subways should be looked upon as a necessity. Until we have them, well-made roads and well-maintained road surfaces are impossibilities in London.

The paving materials at present in use will be difficult to improve. Granite sets, where used, should generally be smaller, as well as properly founded. The macadam roads are, however, very far from being as good as they might be; they are neither properly made, nor efficiently maintained.

It is customary now, for some roads and streets, to make a good substratum of concrete; but the surface seems to be made under the supposition that the broken granite will pack itself, and that granite lumps approaching the size of cocoanuts can be well compacted by the steam roller. Nothing can be further from the actual results. A good deal of crushing and pushing into the simulation of a compact as well as a level surface of granite goes on during the rolling, but the road crust is of uneven density, looseness, and tightness when the roller steams off home. The pounding by horses' feet, and the pressing and grinding by the narrow wheels of ordinary vehicles, fast and slow, then commences. The looser places are tightened; the harder, better packed parts remain more or less obdurate, and the road surface soon becomes a dirt and rock representation of a choppy sea. Every horse-vehicle that rattles over the road in this condition increases the imperfection, and soon the humps and hollows are enough to make themselves felt in a four-wheel cab, or to throw a cyclist off his saddle if he moves at more than two miles an hour. Destruction then is very rapid. Every wheel descending at from six to 10 miles an hour from a hump will hit the hollow, or the sides of adjacent bumps, with a hammer of from half a hundredweight upwards, wielded with a striking velocity of 1,000 feet a second, which the recoil of the carriage springs gives it.

A road once made is left for a considerable time to take care of itself. If our road authorities would spend a pound to save two, they would employ gangs of well-directed men from within a few days of the opening of a newly-made road, to inspect, pack, level, and make good every defect in the stage of its incipient evidence, breaking the big lumps *in situ*, and raising and packing the soft hollows. In this way the light, quick travelling iron wheels would come to the aid of the road-maker, instead of doing nothing but destruction.

For the making of the road it is necessary, in the first instance, that the rock-breaker should be given more work. The granite should be broken up to one-third the ordinary size used in and round London. It should then be packed in place by apparatus that can easily be devised, so that every piece approximately fits against all the pieces surrounding it, as it does when small-sized metal, such as that used in the Cambridgeshire roads, is used. The steam-roller then does better work from the first, and does it more quickly. The attempt to compact the large road-metal often used by the steam-roller is about as successful as an attempt would be to compact, by the same means, the large pebble reaches of the Chesil beach, or that at Aldborough.

(To be continued.)

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Specifications Published.

THE following is a List of Specifications recently published, and obtainable at the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform charge of 8*d*. per copy. Owing to the enormous pressure upon our columns it has been found impossible to deal in any other form with the accumulation of patents now being taken out in connection with automobilism. As far as possible, a selection for special mention is made by the Editor from the more prominent inventions:—

Applied for during 1896.

22,935.	F. W. LANCHESTER, Worcester. Gas and oil-motor engines.
20,046.	O. IMRAY, London. Compressed-air motors.
19,823.	F. PARKER, Brighton. Motor road-carriages.
16,424.	R. HADDAN, London. Motor-cars.
25,202.	J. G. STIDDER, Croydon. Motor road-cars.

AUTOMOBILISM AND THE LONDON FIRE BRIGADE.

THE articles which have during the past few months appeared in the AUTOMOTOR have had the effect of stirring up the London County Council to something like inquiry, and lately we have been approached unofficially by various people interested to know what is being done, or rather what can be done, to improve the London Fire Brigade. Long before the disastrous Cripplegate fire we expressed certain opinions* on the plant and equipment of the Brigade which were only too abundantly confirmed by that conflagration. Since then there have been not a few other serious fires, and, as we pointed out months ago, that a fire in London invariably means the total destruction of the premises in which it occurs. It is reassuring to know that not only the members of the L.C.C. but also the officers of the Brigade seem to see the necessity of "doing something." At least, we gather this from various evidently "inspired" utterances and "interviews" that have recently appeared in the Press. For ourselves, we cannot say with certainty what is being done in the matter, as our criticisms having apparently given offence to the members of the Committee and officers of the Fire Brigade, we are not favoured with the indulgence accorded to other journals. Some months ago we wrote Colonel Rotton, the Chairman of the Fire Brigade Committee, asking him to receive one of our technical staff. He sensibly, we think, declined; he said he was "busy." Quite recently, too, Dr. Collins, the Chairman of the Council, likewise declined to be seen. Of course, the reason is sufficiently obvious, and we need not enlarge upon it. To the lay Press the Brigade Committee and staff, for reasons also sufficiently obvious, are *so* accessible and grant interviews gladly. Thus the *Daily News* lately published an account of an interview at Headquarters, and obtained some interesting although for our purpose not very useful information. The *St. James's Gazette* has also been accorded an interview with Commander Wells, R.N., on the subject of automobile fire engines. From the published account we should say that the gallant officer knows but very little about automobilism, while the scribe knows less. Neither are agreed as to the source of energy, but the Commander thinks it will be steam, but not necessarily "coal-steam" (*sic*). We are then told that electricity and gas are too limited. "You can't pull up at a lamp-post and get a fresh supply of electricity." Well, we may ask, why should you? The Commander continues:—"Gas, too, is just as bad; for you've got to carry cylinders, filled at so much pressure—so many atmospheres—and if you run short, you're done for. But oil you can get pretty nearly anywhere, and so you can coal. Then there's another thing quite as important. If your motor-car breaks down—well, you can get a hansom or walk. But that's no use to the Fire Brigade. I must have a machine that can start off at once. Don't you think lightly of the horses—they work all right. You may see a pair look a bit fagged now and again—perhaps they've a young coachman, who hasn't reckoned on the distance he had to go and the weight to be drawn. But you can always rely on the team for a sprint if you want it. Suppose the motor-engine won't budge—well, we're stuck altogether. It's no light matter to think of sending round for a specialist to come and see what's wrong while the house burns down, is it?" I assented, replies the interviewer, and dodged in a question as to the experiments. "Oh, yes," replied Commander Wells; "I'm busy on it; but I can't say we're much beyond the toy stage yet. There's one of my men on it now," he added, stamping sharply on the floor to hint to somebody underneath to moderate his hammering. "We've had things here from the private makers to try, and they're all right, perhaps, but they're no good to us. We're trying to keep in close touch with the market, though we're a bit behind in some ways—there isn't such a thing as a ball bearing in the Brigade, for instance. Still, we're working away; but we're only in the experimental stage yet."

It will be gathered from the above that the ideas of the gallant Commander are rather vague. It evidently does not occur to him

* *Vide* AUTOMOTOR, June and July, September and November, 1897.

that with the aid of a thermal storage plant a steam automobile could "start off at once" and be round the corner before the crew could get on board. We might also tell him that if he thinks he will learn anything serviceable to the public by conducting "toy" experiments with the aid of "one of his men," he is woefully mistaken; he will learn nothing of practical use. We are glad to note that he admits that his charge is "a bit behind in some ways." Yes, a very long bit, we think. Commander Wells is, we are sure, sincerely desirous of improving the Brigade in every way, and so, we think, will be the members of his new Committee. We therefore presume to give a little advice to all concerned. It is no use wasting public money and time in conducting "experiments," whether "toy" or otherwise, for this reason—automobilism consists in the solution of problems of more difficulty than are found in railway engineering; they can only be successfully attempted by well-educated engineers. Commander Wells is not an engineer, and, with no disrespect to him or his officers, we assert that there is no one in the Brigade who is qualified or competent to advise on the construction of fire automobiles. One of the reasons why improvement is so slow in the Brigade is that apparati are submitted to the judgment of men who, good enough as practical firemen, are yet without the requisite scientific and technical knowledge to enable them to form a competent opinion. Thus chemical engines are condemned by men who have never learned anything of chemistry or engineering. Hence any conclusion that may be reached by the Brigade on fire automobiles must be regarded as merely lay opinion. We think that one of the first things the new Fire Brigade Committee should do is to obtain from Commander Wells a statement of his requirements for a fire automobile—that is, the speed to be obtained under various conditions, the volume of water to be projected per minute, and the height of the jet. A specification should be got out, and some leading firms be asked to tender on a liberal basis. There would be no lack of contractors. Firms do not care to spend £1,000 or so on a machine they cannot sell, and hence fire automobiles are not yet used in England—not because the problem of their manfacture has not been solved, but because neither Fire Brigade Committees nor Fire Brigades have yet sufficiently realised the vast possibilities of automobilism. Such bodies are intensely conservative, and regard new means which they do not understand with natural enough suspicion. But to say, as do many such persons, that in an age which has produced the automatic gun, an automobile torpedo, and an automobile street car, a fire automobile cannot be produced, is too absurd for serious discussion. Commander Wells and his Committee may rest assured that if they want fire automobiles they can obtain them.

LES POIDS LOURDS.

Report of the Commission—IV.

(Concluded.)

IN their concluding observations the Committee express regret that the programme of the competition does not admit of any comparison being made between the different vehicles; for otherwise it would have been possible, when attempting to establish a classification between the competitors, to make a comparative study of the different methods used by the builders to solve the problem. The difficulties to be overcome might have been better understood, and the way to provide satisfactory vehicles in all their parts might have been shown.

However, in order to facilitate research, we exhibit in a single table on next page the net cost of the different vehicles.

It is probably useful to repeat once more that this net cost applies only to vehicles working under the same conditions as in the competition. As much with regard to the nature and outline of the course to be followed as to the speed that it would be possible to adopt effectively during the competition, the competitors have had an absolute freedom of movement quite natural in driving in the open country, but inadmissible in towns where the traffic is subjected to many regulations. The reader must, therefore, be on his guard against calculations which would have for a foundation figures that had not been carefully studied of the ways to follow, and the special exigencies of the services that would be in view.

Much of the working cost mentioned in the following table would have certainly been more advantageous if the builders of the vehicles had better understood the ruling idea of the competition. Probably, in order to gain a few minutes on the distance, they have taken advantage of the minimum of a ton load imposed in the programme to place on their vehicles weights less than that which they have declared elsewhere to be their normal loads. They have thus succeeded in augmenting the speed which serves as a basis for the working of the vehicle, but they have, to their cost, miscalculated the gain.

However, the net cost as calculated shows that, from now, the mechanical traction on roads is capable of securing, with a decided profit, regular transport services for passengers and even goods.

For instance, suppose a service of this kind would be between a railway station and a locality situated at a distance (which, in order to give an idea, we will say is 9¼ miles). Admitting there is a daily traffic of about 40 passengers, with their luggage, as well as some parcels and 8 tons of goods, for the passengers and the parcels the scale of charges of the tramways is as follows:—

1st class passengers	—16	centimes	per mile.
2nd ,,	9·7	,,	,,
Per ton of parcels	68·0	,,	,,

As regards goods, they charge usually—

1st class goods, per ton	—26	centimes	per mile.
2nd ,, ,,	22·6	,,	,,
3rd ,, ,,	16·0	,,	,,
4th ,, ,,	13·0	,,	,,

But the scale of freight charges lately made for the tramway at Vals-les-Bains, at the Aubenas Station, are—

1st class goods, per ton	—34·5	centimes	per mile.*
2nd ,, ,,	51·6	,,	,,
3rd ,, ,,	47·0	,,	,,
4th ,, ,,	39·0	,,	,,

An automotor vehicle can make three journeys daily, coming and going—altogether 56 miles. If there are from 10 to 12 places in a vehicle for an average of two-thirds of its seats occupied, the corresponding movement of passengers going as well as coming would be about 40.

For goods, a vehicle capable of carrying 3 tons, but usually carrying an average of 2, can make two journeys, going and coming, daily—altogether 37 miles. On an average the traffic would be 8 tons. Under these conditions, the daily receipts per mile would be 8·31 francs, or annually 8·31 × 365 = 3033·15 francs per mile.

In the case of a tramway these takings would just cover the cost of working, even with the best and most economical management. As with the original capital used in the making of the road this could not be less than 48,387 frs., or £1,935 per mile, the annual interest and instalments would be entirely in the hands of the department, town, and state, which usually gives a grant of half. Even at the low rate of 4 per cent., the annual interest divided between the town, department, and state would be 1,935 frs., or £77 per mile. On the other hand, the preceding figures show that a regular service established with most of the competing vehicles—viz., those that took part in the trial—would give, with the takings, a daily profit of about 12·9 centimes per mile, corresponding to 12 frs. per day for the 9¼ miles, or 4,380 frs. per annum (£182 10s.).

It must be taken into account that this is an annual net profit of 4,380 frs., after having deducted the interest on instalment of the capital in the calculation above made. In the example we have just given the service can go on without any State grant.

It should be remarked that the first cost of establishing a service consisting of an automobile omnibus, a 3-ton lorry, and a reserve vehicle would be about 63,000 frs., or £2,520.

The very considerable advantages can be seen at once of the substitution of automotors for tramways on roads and to railways when a line of service is yielding too little to pay the original capital used in establishing the line. The great advantage of automotors is that they can be tried anywhere—where tramways are bound to fail. Besides, there is this other advantage, that as soon as the traffic is sufficiently developed to justify the expense of a line the automotor cars can be used in establishing a service in another direction.

Before concluding this long report it is, perhaps, as well to say a few words about the aim of the Automobile Club Committee when

* In this translation we have, as far as possible, rendered the metric units into British in order to facilitate comparison. Francs are taken at 25 = £1.—ED.

* The Cheval Vapeur = ·9863 of the British Unit.

they announced for October, 1898, a new competition of heavy weights on the same lines and conditions.

Several competitors have been rather doubtful about this announcement, thinking that they saw in it an intimation indirectly given to those interested in the business, so that they, the latter, should not organise regular transport services before this new competition gave them the knowledge of the progress made in generators, motors, and other parts of the vehicles. The Committee has never entertained such a thought. They certainly have never affirmed that there is no progress to be made, or that from henceforth everything is perfect in all parts of the automotors; but they do not see any reason why it would be useful to postpone the establishment of any service which can bring in a profit with the vehicles at present in use, without waiting for the utmost perfection.

If builders in a year or two bring to perfection a more economical motor, or one with a greater commercial speed, nothing will prevent their being utilised on lines already established, and with a traffic sufficiently developed to necessitate a better stock. The vehicles first bought will then be used for the service of new localities, or, slightly altered, will be passed over from passenger to goods traffic. Is not this what is done every day on railways? An engine has been made for an express train; when a greater speed is required a more powerful and more perfected one replaces it; then it is used as a goods train until the day arrives when a new one is substituted for the second, which is then passed over to another line. Has any one ever seen an engine destroyed? It will be the same with automotors. More perfect ones will progressively be substituted for those first bought, but these will be made use of for other minor services, as, having been paid for, they will continue to turn in profit.

In announcing a new competition for heavy weights in October, 1898, the Committee wishes to let all builders know that they have at their disposal profitable and economical means of making their vehicles appreciated by those interested, viz., Directors of Transport Corps, and Municipal and County Councils.

MOTOR-VEHICLES WITHOUT DIFFERENTIAL GEAR.

THE Steam Carriage and Wagon Company (Limited), of Chiswick, have devised an arrangement of gearing having as its object the production of motor-propelled vehicles of simple construction that may be readily steered without the use of the so-called Jack-in-the-box motion on the counter-shaft sometimes employed in such vehicles. For this purpose each driving wheel of a pair is driven from a separate counter-shaft, these two counter-shafts being arranged with their axes in a common straight line, and each having fixed on one of its ends a pulley; the two pulleys are juxtaposed and are driven by a common belt, itself driven directly or indirectly by a motor of any suitable kind, the arrangement being such that normally the two pulleys will be driven at a common speed, and that consequently the two driving wheels will be driven also at a common speed for propelling the vehicle in a straight line. In connection with the steering gear there is provided a belt shifting or striking device of any convenient construction such that when the steering gear is actuated, to cause the vehicle to depart from a straight course, the belt shifting or striking device will be operated so as to shift the belt wholly or mainly on to the pulley from which is driven that driving wheel of the pair which is then to travel through the greater distance in a given time. This may be effected in various ways.

Referring to the accompanying illustrative drawings—Fig. 1 is a sectional elevation of so much of a motor-propelled vehicle as is necessary to illustrate the invention; Fig. 2 is a plan; Fig. 3 a front view; 1, 1ᵃ are the driving wheels, and 2, 2ᵃ are the two counter-shafts which are geared by chain or other suitable gear at the outer ends of the said shafts as shown, one with each driving wheel; pulleys 3, 3ᵃ are fixed one on the inner end of each counter-shaft, each pulley having one face, so that the two pulleys constitute, as it were, one broad-faced pulley composed of two parts a slight distance apart, and the driving belt, 4, is normally equidistant from either outside edge of pulley face. 5 is a motor of any suitable kind, on the shaft of which is fixed a driving pulley, 6, around which the belt, 4, passes. The striking device, which is shown in detail in

FIG. 1.—ELEVATION.

Fig. 4, comprises a slide, 7, adapted to be moved cross-wise in guides fixed to the underframe of the vehicle and carrying a pair of depending arms, 7^a, between which the belt passes and which are or may be fitted with rollers, 7^b. At their lower ends they are connected by a bar, 7^c, that extends laterally through a slot in one arm of a bell crank lever, 8, this arm being connected to the bar, 7^c, by means of springs, 7^d, interposed between it and fixed collars, 7^e, on the bar. The striking device is, by these springs, held normally in a position to keep the belt on the central portion of the periphery of the compound pulley. The springs also allow the steering gear to be rapidly operated as they permit it to be moved in advance of the belt which is subsequently caused to move over by the spring compressed during the movement of the steering gear. For shifting the striking device the bell crank lever, 8, is connected by a rod, 9, to a crank disc, 10, that is partially rotated when the steering gear, which may be of any suitable kind, is operated. In one form, the steering wheels, 11, 11^a, each run on a separate short axle, 12, able to be turned about a vertical axis and forming one arm of a bell crank whose other arm, 12^a, is connected by a rod, 13, which is operated through suitable connections from the steering handle. 14 is a hand-wheel

FIG. 2.—PLAN.

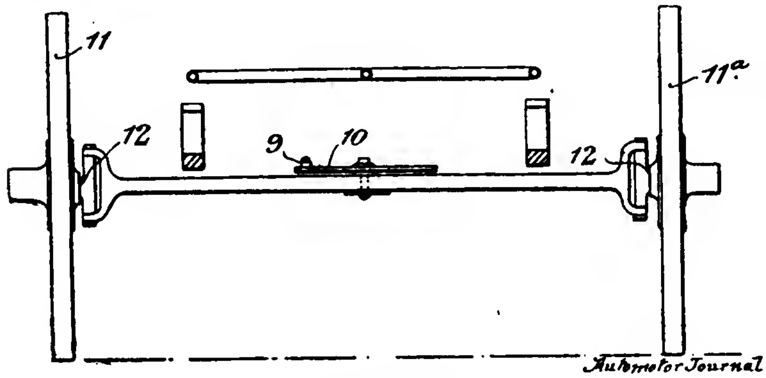

FIG. 3.—FRONT VIEW.

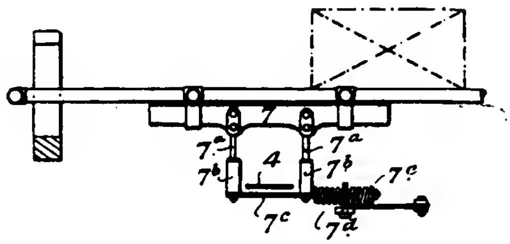

FIG. 4.—STRIKING GEAR.

FIG. 6.—PLAN.

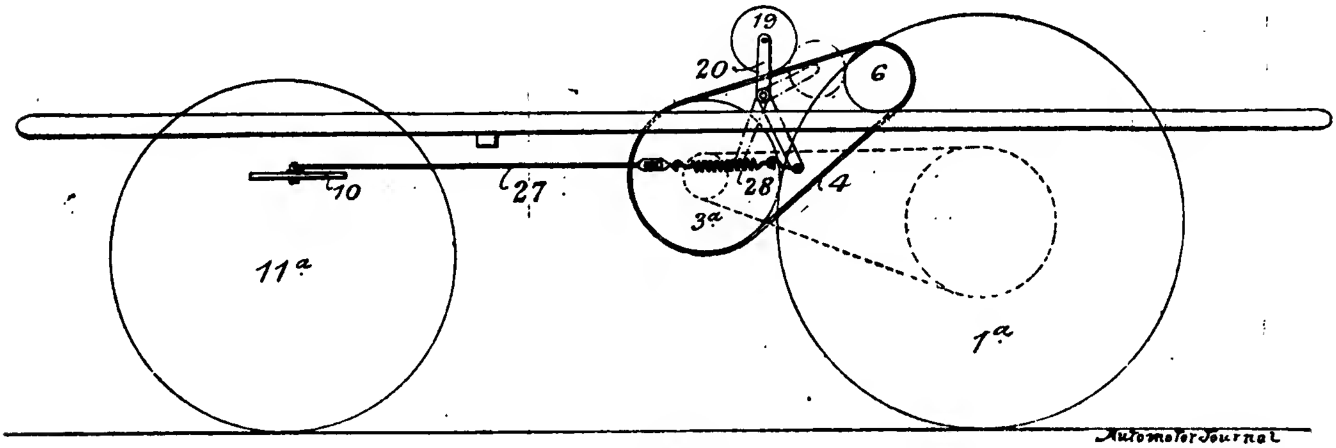

FIG. 8.—ELEVATION.

with handle, 15; the spindle, 16, of the hand-wheel has fixed to its lower end a sprocket wheel, 17. The crank disc, 10, is formed with sprocket teeth around its periphery and is driven from the wheel, 17,

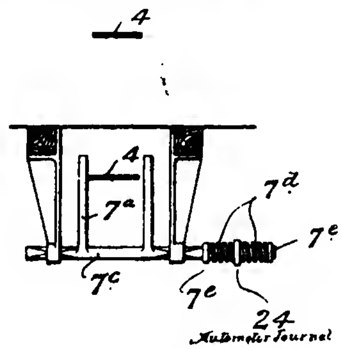

FIG. 7.—STRIKING GEAR.

by a chain, 18. For keeping the driving belt, 4, taut when required, a jockey pulley, 19 (Fig. 1) is journalled in bearings at the end of a lever, 20, that is connected by a rod, 21, with a hand lever, 22, fitted with a locking rod, 23, the arrangement being such that the speed of the driving may be regulated by applying more or less pressure through the jockey pulley, 19, upon the belt, even whilst the motor is running at a constant speed.

Figs. 5, 6, and 7 are views corresponding to Figs. 1, 2, and 4 of a modification of the arrangement above described in which a lever, 24, of the first order is pivoted at 24a between the counter-shafts, 2, 2a, and the shaft, 25, whose ends carry the axles of the steering-wheels; the lever, 24, is attached by a slot and pin connection, 26, to the disc, 10, of the steering gear and to the striking device, as shown. In this example the striking device comprises a pair of arms, 7a, projecting upward from a bar, 7c, that works in guides fixed to the underframe of the vehicle; the bar, 7c, passes through a slot in the end of the lever, 24, between which and fixed collars, 7e, on the bar, 7c, are interposed the springs, 7d.

Figs. 8 and 9 are views corresponding to Figs. 1 and 2, and show another modification where, instead of driving the two pulleys, 3, 3a, by a common belt, 4, each pulley is driven by a separate belt provided with a jockey pulley, 19, similarly mounted to that shown in Fig. 1, and connected with the steering gear by rods, 27, and springs, 28, the arrangement being such that normally both belts are kept taut, but that when the steering gear is operated to turn the vehicle from a straight course, the one jockey pulley will relieve or release its belt sufficiently to slacken the driving of, or to cease driving, that wheel which has to pass for the time being through the shorter or no

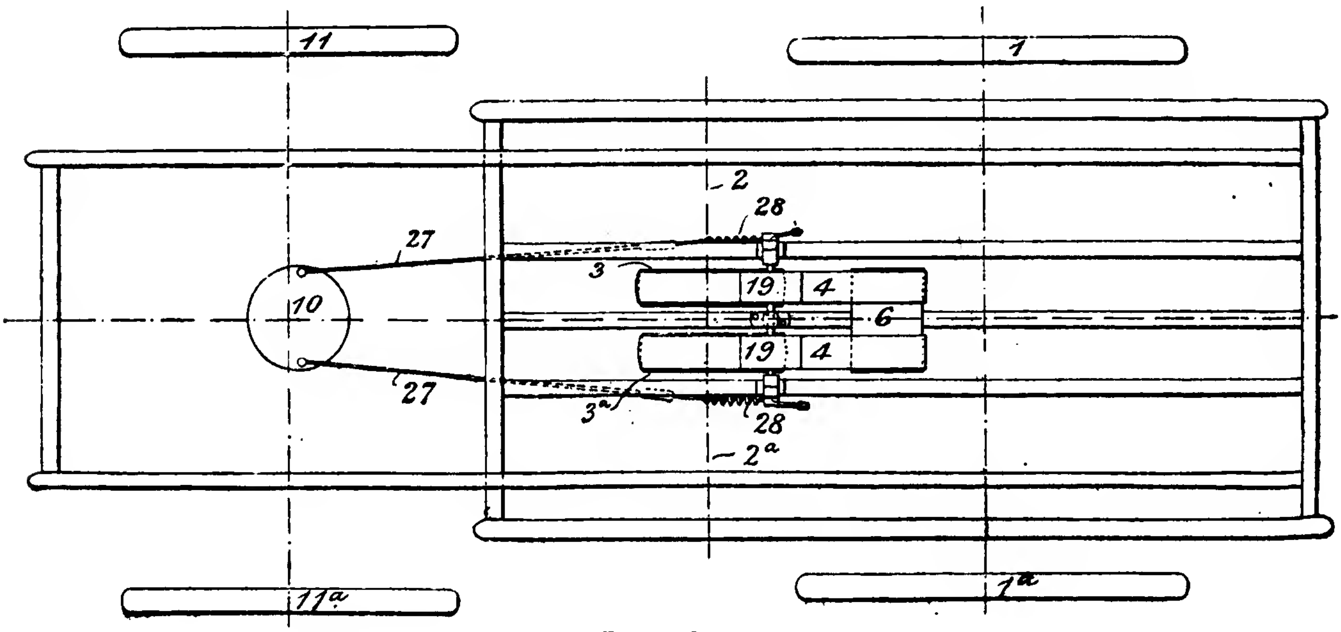

FIG. 9.—PLAN.

distance. The normal position of each jockey pulley is midway between the two positions indicated; the full lines indicate the position when the belt is first put on, and the dotted lines indicate the position when the belt has become stretched and the pulley has been adjusted to keep it taut. In this case there is no provision for varying the speed by slackening jockey pulleys. In some cases motor-propelled vehicles may be provided with driving arrangements constructed according to this invention, but without striking devices, jockey pulleys such as above described, or the like adapted to be operated from the steering gear; in such cases the relative speeds at which the pulleys 3, 3ª, are driven will, on the steering gear being operated, automatically vary owing to the difference in resistance to driving then offered by the respective wheels, 1, 1ª, to which the pulleys are geared and the consequent slip of the belt on the pulley geared to the wheel which has to travel the shorter distance.

LIQUID FUEL.

MR. J. S. ZERBE, in the course of an interesting article in the *Mechanical World*, on some experiments in liquid fuel burning, says:—In order to give some idea of the system adopted by the United States naval authorities it will be necessary to point out a few of the distinguishing features employed in the old systems of using fuel oil, and, primarily, it should be observed that there seems to be a general impression among all who have heretofore entered this field that the atomiser or burner is the essential feature in the process of burning oil. The burner is simply a stoker, and while it is true that one burner may stoke better than another, this advantage is a small one when compared with the firebox equipment. A firebox which is not specially equipped to burn liquid fuel will never do good work, however perfect the burner may be. Over 700 patents have been obtained for burners, and less than 30 for firebox equipments. This shows most emphatically how vigorously inventors have struggled at the wrong end of the problem, and explains why failures are so common the world over. Furthermore, it may be said that there are two ideas predominant in the minds of liquid fuel experimenters beyond which they seemed loth to go. The first is that a candle or barrel-shaped flame is essential, and that the flame should be ejected against a baffling wall erected within the firebox. These features are primeval in their character, fundamentally wrong in their operation, and radically deficient in results when applied under any type of boiler. The essential thing is to perfectly aërate the hydrocarbon gases evolved by the heat of the combustion chamber. Where oil is thrown into the heated chamber the gases form rapidly, an immense expansion takes place, and the interior of this conical flame cannot receive the requisite amount of air to produce perfect combustion; hence, owing to the rapid movement of the mass, it passes into the tubes with a large portion of unconsumed particles, and thus passes into the flue and out of the stack in the form of smoke. At this point the inventor sought by a new expedient to arrest the flame, break it up, and produce a mixing operation by introducing a baffling wall. The flame in striking this wall would naturally be deflected upwardly, so that it would strike the boiler sheet or tubes, and thus form a zone of intense heat at the wall, which has been found to be very destructive to the boiler. But this is not all. The wall naturally diminishes the size of the combustion chamber, which should in all cases be larger than for coal in preference to being smaller. There is also a very serious defect in the old style so-called oil equipments in the manner of admitting air to the firebox. In all cases it has been customary to admit air in a mass, either around the burner or into the firebox at one point through the grate surface. This results in producing a disagreeable noise. Cold air is admitted to the boiler, and when so supplied in a body the desirable mixing operation is not accomplished to produce a steady, uniform flame of great intensity. Some inventors provide conduits and retorts for heating air, while others provide a vaporising chamber for the oil; but all these attempts to utilise auxiliary mechanism or contrivances outside of the firebox to prepare the fuel and air are needless expenditures of force, make the system complicated and difficult to regulate, and are useless expedients when compared with the "direct conversion" system, which contemplates the taking of the fuel and the oxygen in the natural state and producing complete combustion within the firebox itself. Manifestly such a system is much simpler in construction, more easily operated, and less expensive.

The construction of such a system, therefore, contemplates the following features:—

1. The firebox must perform the entire operation.
2. The grate surface must not be decreased in area.
3. The heating surface of the firebox should not be diminished.
4. The flame should cover the entire grate surface.
5. There should be no retarding wall within to produce a great zone of heat at one point.
6. Cold air must not be permitted to enter the firebox, and it should never be admitted in a mass.
7. The shape of the flame should be such that the air will freely mingle and aërate the entire mass.

To accomplish this a very simple form of firebox construction was provided. The entire grate surface is covered with a single layer of specially prepared firebrick. This brick has on one side ducts, partially across one face, and these bricks are nested against each other at an angle of 45 degrees, so that when the bars are covered small ducts are formed through this bed over the entire surface. This bed formation has several very important functions. It breaks up the air, so that it enters the firebox in small jets, and after the burner has been in operation a short time the entire bed is heated up to incandescence, thus heating the air as it passes through the ducts. The bed, when in this state, also acts as a substitute for an incandescent bed of coal, giving out radiant heat to the boiler, and thus economising fuel. The burner or atomiser is specially adapted for use with this brick bed, as it is designed to throw a fan-shaped spray, thus causing the flame to cover the entire bed, so that when the subdivided jets of air come up through the ducts in the bed, every part of the flame has its requisite supply of heated air, which readily commingles with the hydrocarbon gases. The burner is simple in construction, being composed of two castings, an upper and lower part, substantially similar in construction, the upper part having an oil supply connection and the lower part an air or steam inlet. These inlets terminate in open transverse channels, from which radial grooves extend to a point near the forward circular end of the burner. The contact faces of these ducts are dressed off, and between them are placed three copper gaskets or diaphragms, the intermediate one of which has its forward edge extending to the circular rim of the burner, while the upper and lower gaskets have V-shaped notches cut therein, the bases of which communicate with the radial ducts. These gaskets are composed of No. 30 gauge copper or even thinner material, and as the oil and compressed air, or steam, are forced through the small interstices, the V-shaped openings permit the liquid and steam to expand horizontally, producing a continuous sheet at the mouth of the burner. The two parts and the gaskets are held together by means of bolts. This form of burner has several distinct advantages. In cutting the gaskets a greater or less number of these ducts can be brought into action, or the flame can be horizontally disposed over a wide or narrow area, dependent on the shape of the firebox. By using thicker or thinner gaskets the capacity can be increased or decreased; and as the oil channel which supplies all the ducts is horizontally disposed, the burner can be directed at any angle desired without having an undue flow of oil to the central or the side ducts. In the torpedo-boat tests compressed air was used.

Better Late Than Never, or Has It Been Asleep.—The *Yarmouth Advertiser*, like most of the Press, is manifesting somewhat tardily an interest in automobilism, and so in its issue of the 5th inst. it gives an account, as a news item, of the run from London to Richmond that took place on November 29th of last year! Our contemporary speaks in terms of mild appreciation of automobilism, and sums up the question in the most judicial manner, thus:—The possibilities of scientific development are so vast that a principle once proved to be workable, the details to make it commercially acceptable may be regarded as no more than a work of time (and a very long time, too). The application of electricity, too, is yet in its infancy (of course), and, compared with what is known, an inexhaustible field of discovery remains open. That animal power will eventually disappear from the streets is hardly to be anticipated within measurable time. (How true!) But that the demand for horses will steadily lessen is tolerably certain. The appliances of life and of commerce tend more and more to complexity and the disuse of muscular force. The motor-car, whatever its initial difficulties, is the road vehicle of the future, to the cheapening of conveyance, and the facility of trade.

R

THE STREET TRAFFIC OF LONDON.

Our contemporary, the *Railway News*, in the course of an interesting and carefully compiled article on this subject, says:—In 1865 public interest was largely engrossed by the discussion of what was to be done for dealing with the important question of the metropolitan traffic. A generation has passed since that time, and the population, which at the census of 1861 stood at 3,250,000, is now, according to the last census of 1891, increased in density to 5,633,000, or an increase of over 2,250,000. The public mind was so engrossed with the importance of the question of providing adequate accommodation for the growing population that the united wisdom of Lords and Commons was concentrated in a Royal Commission, to consider and report upon the best mode of dealing with the street traffic of the metropolis. Many Bills were submitted to Parliament for the construction of railways, and other schemes for dealing with this important question. The outcome of the labours of this Commission was the proposal of a scheme of underground railway which should form what has now become the "Inner and Outer Circle" of railways. Two of these projected lines—namely, the Metropolitan and District—now carry 135,000,000 passengers. Since their completion two other lines have been constructed—namely, the North London and the City and South London—these two last year carried 56,000,000 passengers. Tramway companies have since been introduced, radiating in various portions of the area, and these together bring into the district 150,000,000 passengers. Four of the great railway companies—Great Eastern, Brighton, Chatham, and South Eastern—together carry 220,000,000 passengers.

We gather from a police return that there are 3,190 omnibuses and 1,378 tramcars in the metropolis, making together 4,568 public vehicles. Added to this there are 3,583 four-wheel cabs and 7,923 two-wheel vehicles, or our familiar friends the "hansom" and the "growler." Together we have a grand total of 16,076 cabs and omnibuses and tramcars to aid in the locomotion of the population of London. The General Omnibus Company run 1,151 vehicles, and these carry 172,000,000 passengers; the Road Car Company runs 350, and these carry 58,000,000. But there are still to be included in the aggregate of omnibuses licensed by the Commissioner of Police 1,650 omnibuses that are not owned by the two leading companies. It has been asserted that the 1,650 not owned by the two companies convey one-half of the average of those in the principal thoroughfares, and that these together aggregate a total of 100,000,000 passengers. So far as the street traffic of the metropolis is concerned, as represented by the vehicular proportion of its population, we have therefore the astounding figures with which we have to deal in estimating what will be the probable requirements for the underground London railway system which is already being steadily constructed, and for which still further Parliamentary powers are authorised by the Legislature. Here is an estimate of the number of travellers by the Metropolitan and other railways entering London, and the number of passengers by tramway and omnibus:—

Metropolitan; Metropolitan District; North London; South London	191,000,000
Suburban traffic of—	
Great Eastern; Brighton; Chatham; South Eastern	110,000,000 (estimated)
Great Northern; Great Western; Midland; North Western	100,000,000 (estimated)
Tramways in London, official returns	150,000,000
Omnibus, General (1,150)	172,000,000
Road Car (350)	58,000,000
Other omnibuses (1,650) (not enumerated)	100,000,000
	881,000,000

From an American exchange we learn that the Diezel Motor Company has been incorporated at Albany with a capital of $1,000,000 in $100 shares, beginning business with $600,000 capital. The directors are Charles F. Wilken, Percy Thorpe, John C. A. Sutor, and E. Emmet Doherty.

Taxation of Motor-Cycles in France.—The French Chamber of Deputies on the 11th inst. decided that the tax on motor-cycles should be trebled as from April 1st, and that every machine of the kind should have a label attached with the name and address of the rider.

Naturally.—At a meeting of Dunoon Commissioners, on the 8th instant, a long letter from the Dunoon and District Carriage Hirers' Defence Association was read, pointing out that the narrow roads in the burgh were quite unsuitable for motor-car traffic, and if allowed to continue would be a great source of danger to themselves and the general public, especially during the summer season. After an animated discussion the matter was remitted to a committee. The present licenses expire in May.

A New Motor-Vehicle for Heavy Traffic.—The Liquid Fuel Company, of Cowes, Isle of Wight, inform us that they have lately built and run a steam-van, using petroleum as oil fuel, and from actual tests have found that it will easily carry loads of 3½ tons on grades of 1 in 10, and at a cost of about 2½*d.* to 3*d.* per mile. This van has pivoted axles and steers very easily with a load of 3½ tons. Add to this the weight of the vehicle, 2 tons, with the necessary fuel and water, and there is about 6 tons on the wheels.

Electric Carriages in Berlin.—The *Elektrotechnische Zeitschrift* of February 24th contains an illustrated description of two types of electric carriages which are being demonstrated in the streets of Berlin. These carriages, which have been built by one of the leading cycle companies, are fitted with bicycle wheels and pneumatic tyres, which can be inflated to a pressure of 120 lbs., whilst the bodies are supported on steel tubular frames. The wheels have ball bearings, and steering is effected by means of a lever connected with the front pair of wheels. Each carriage is equipped with a motor suspended from a steel frame lying parallel with the rear axle, the latter passing through the hollow armature shaft, and being driven by differential gearing from a toothed wheel arranged on that shaft. The battery consists of 44 cells contained in four boxes, the total weight being 8 cwts. It can be charged at a pressure of either 65 or 110 volts, and the connection allow of four different speeds being attained, three by altering the disposition of the battery, and one by weakening the motor field. The carriage is provided with a watt-hour meter, which indicates the condition of the battery, and the total weight complete is 16 cwts. It is possible to attain a speed of 12 miles an hour, and one charge will allow of the carriage covering a distance of 27 miles before the cells require to be re-charged. The carriages possess a pleasant appearance, having been built specially for the work.

A Medical Man on Motor-Vehicles.—Dr. T. Prichard Roberts (St. Albans) writes to the *British Medical Journal*:—Some weeks ago in that paper a question was mooted as to the best autocar or motor for the use of a medical man. After an exhaustive trial of a motor-tricycle built for me by the Beeston Cycle Company, Cheylesmore, Coventry, which I have run nearly 500 miles during the last month without any accident whatever, I thoroughly recommend this make. There is little trouble in either starting or stopping, good break power, and scarcely any noise or vibration. Petrol or doubly-distilled benzoline, of specific gravity 680, is the oil used for propulsion, which costs about 1*s.* per 100 miles. Tube ignition is preferred to the electric spark for the explosion of the vapour. The speed can be regulated to anything between 4 miles and 20 miles an hour by a small lever immediately in front of the rider. With an extra-power cylinder any ordinary hill can be climbed, and the steepest with a little assistance by pedalling. This is a great boon to a medical man, as he can cover from 50 to 60 miles a day with little exertion and at a trifling cost. A motor is easily got ready at night. On arriving at a patient's house the lamp can be turned out, and the machine put away in a small space. I may add that the petrol can be obtained at Messrs. Carliss, Capel, and Co., Chemical Works, Hackney Wick, London. Commenting on this the *British Medical Journal* says:—"The prime cost of the machine is not mentioned, but the main objections to its use appear to be that the rider is very much exposed to the weather; that on wet roads the travelling is very heavy, and that he is compelled to dismount on coming to a newly-stoned piece of road."

Semi-Official Journal of the Association	THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SELF-PROPELLED TRAFFIC ASSOCIATION

(INCORPORATED).

LIVERPOOL CENTRE.

Programme for 1898.

March 29 ..	Paper: "Recent Improvements in Accumulators and in their Application to Traction on Common Roads." Mr. J. T. NIBLETT.
April 19 ..	Paper: "Arrangements for the May Trials." The HONORARY SECRETARY.
May 24–27 ..	Trials of Motor Vehicles for Heavy Traffic.

MR. JOHN A. BRODIE, M. Inst. C.E., has been elected a Vice-President of the Liverpool Centre of the Self-Propelled Traffic Association, in succession to Mr. H. Percy Boulnois, M. Inst. C.E. Dr. H. S. Hele-Shaw, M. Inst. C.E., has joined the Council.

Trials of Motor Vehicles intended for Heavy Traffic.

THE following gentlemen have been selected to act as judges:—

From London Council.

Sir DAVID SALOMONS, Bart., Pres. S.P.T.A.
Professor BOVERTON REDWOOD, F.I.C., F.R.S.E., &c.

From Liverpool Council.

Professor H. S. HELE-SHAW, M.I.C.E., &c.
JOHN ALEX. BRODIE, Esq., M.I.C.E.
EVERARD R. CALTHORP, Esq.

The following gentlemen will hold themselves at the disposal of the Council to act as reserves, if necessary:—

S. B. COTTRELL, Esq., M.I.C.E.
H. B. WEST, Esq., M.I.M.E., M.I.N.A.

In connection with these trials the following circular letter has been addressed to members and others:—

Liverpool.

DEAR SIR,—The support of all members of the Association is earnestly hoped for in furtherance of these important trials, and I venture to appeal for your financial aid towards the expenses connected therewith.

The estimated total amount required is £750, to be apportioned under the following heads:—

(*a*) Awards and Expenses of Awards.
(*b*) Expenses of Trials.
(*c*) Freight, from port to port, on Foreign Vehicles competing at the Association's invitation.
(*d*) Publication of Report.
(*e*) Entertainment of Foreign Visitors.

With respect to the "Entertainment," I may say that Baron de Zuylen (President), Comte de Dion (Vice-President), and other prominent members of the Automobile Club de France, are expected to attend the trials, and the opportunity offered is thought to be a fitting occasion to return the many compliments paid to members of the Association when on the Continent.

Hoping that you will allow me to add your name to the list of subscribers,—I am, yours faithfully,

E. SHRAPNELL SMITH, Hon. Sec.

"SCIENCE, LIVERPOOL," is the telegraphic address of the S.P.T.A. (Liverpool Centre), which has been specially registered for the purpose of these trials.

THE date of the Dinner to be given to the foreign delegates and others has not yet been definitely fixed, but it will probably be on May 27th.

THE Executive Council of the Automobile Club of France is acting in concert with the Self-Propelled Traffic Association to secure the presence of at least one of each of the chief types of French heavy motor-vehicles. It is doubtful, however, whether these can take part in the trials in consequence of the regulations of the Locomotives on Highways Act debarring the majority of them from competing on the English roads.

TRIALS FUND.

The following subscriptions have already been remitted or promised:—

Sir David Salomons, Bart...	100 guineas.
Mr. Alfred L. Jones (Elder, Dempster, and Co.)	100 "
Mr. Alfred Holt	50 "
Mr. John A. Brodie	10 "
AUTOMOTOR AND HORSELESS VEHICLE JOURNAL	10 "
Mr. W. Worby Beaumont..	10 "
Mr. Maunsell C. Bannister	10 "
Mr. Everard R. Calthrop	10 "
Mr. A. Bromley Holmes	10 "
Mr. Anthony G. Lyster	10 "
Mr. Arthur Musker	10 "
Mr. Henry H. West	10 "
Mr. S. B. Cottrell	5 "
Mr. W. A. Darbishire	5 "
Mr. E. Shrapnell Smith	5 "
Mr. J. K. Starley	5 "
Mr. Geo. H. Cox	2 "
The Right Hon. Lord John Hay, G.C.B., Admiral of the Fleet	2 "
Mr. Geo. F. Ransome	2 "
Mr. John Simpson (Stirling)	2 "
Mr. R. J. Urquhart	2 "
Mr. A. Ludeck	1 guinea.
Mr. J. Walwyn White	1 "
Mr. John Wilson	1 "

As further donations are given, names will be published. Cheques or money orders to be made payable to the S.P.T.A. Trials account, and addressed to Mr. Shrapnell Smith, Hon. Local Sec., and organiser of trials.

Should the amount collected prove to be in excess of the expenditure such surplus will be handed back to the subscribers, *pro rata*.

Referring to the participation of the French automobilists in these trials the President of the Automobile Club de France has written as under to the President of the Self-Propelled Traffic Association:—

Paris, le 19 Février, 1898.

Sir David Salomons, Bart.,
Président de la Self-Propelled Traffic Association.
30, Moorgate Street, London.

MON CHER PRÉSIDENT,—Comme suite à ma lettre du 31 Janvier adressée à M. Shrapnell Smith, j'ai l'honneur de vous informer que le Comité de l'Automobile Club de France après avoir pris connaissance des conditions du Concours que vous organisez pour le mois de Mai, vous a voté des remerciements pour votre aimable invitation.

Il n'est pas douteux qu'un certain nombre de nos collègues ne s'empressent de répondre à votre appel.

Nous vous ferons connaître vers le 1er Avril le nom des personnes qui nous auront manifesté le désir d'aller à Liverpool.

Le Comité a également regretté que les conditions de poids et de dimensions auxquelles doivent satisfaire les véhicules ne puissent permettre à la plupart de nos constructeurs de prendre part à ce Concours.

Nous avons cependant fait un communiqué à la presse de votre convocation.

Veuillez agréer, mon cher Président, l'assurance de mon respectueux dévouement.

Comte Henri de la Valette,
Secrétaire Technique.

Steam Road Vehicles.*

So much has been written and said upon that particular branch of the subject that it is not necessary for us to enter into any statement of the reasons that influenced us in deciding to confine our researches to steam as a motive power, but to give at once the requirements we then laid down, and the attainment of which we consider a *sine quâ non* for ultimate commercial success. Our investigations were to be pursued to give us the knowledge and experience needful to prospective manufacturers; but it is an assured fact that we, and probably every other experimenter, who two years since commenced similar work for similar reasons, have been astounded at the immense amount of difficulty the question offers, and the expense and work its solution requires. Surprise need not be expressed that so few successful cars for heavy loads are at work, but rather that anything has been done, when it is considered what extremely high æsthetic as well as commercial conditions one has to deal with.

Leaving carriages out of the question, we confine ourselves for the present to goods work, as represented by vans, lorries, and wagons generally. To commend itself to an user, and to make it valuable to the future credit of the maker, we considered then, and we are not in any way at present inclined to modify our opinion, that a goods vehicle should in its carrying capacity be as roomy as a horse vehicle used for similar weights, at least twice as speedy, absolutely safe under all conditions of *wear*, *accident*, or *neglect*, as powerful for starting and manœuvring as its equivalent horse lorry, and in its prime cost not exceed to the user three and a half times the cost of one horse lorry with its horses and appointments, capable of moving an equal load on any single average journey. In addition, the public will demand that it must not be noisy or unpleasant, nor injurious to the roads; and the maker, if he be wise, will endeavour not to promote adverse criticism by the creation of any designs too strangely contrasting with existing types. A steam vehicle consists of five essential parts, each of which has had a long existence in other uses, but which, when an attempt is made to combine them in such a car as we specify above, proves itself singularly awkward. These are:—

1. Boiler and feed gear.
2. Engines, transmission and driving gear.
3. Car and framing.
4. Steering.
5. Brakes.

By far the most important of these is the boiler and its feed arrangements.

Our conditions for a van boiler were: — (*a*) Absolute safety against explosion through over pressure or lack of water, and capacity for standing a great deal of either stress before becoming deranged for work. (*b*) High pressure, if possible excessively high, as, say, 400 to 500 lbs. per square inch. (*c*) As a consequence of this to have no water-gauge glass. (*d*) To have no very large volume of water under pressure in the boiler which might, in an accident due to collision or upset, become a danger.

The only boilers that we considered capable of fulfilling those conditions in any degree were water-tube boilers pure and simple, a flash boiler such as Serpollet's, or, as we hoped, it might be possible to evolve a combination of the two. The chief trouble in the use of water-tube boilers of the small size used on autocars is the feed, which presents a series of difficulties not present in any other practice. This difficulty is of course greatly accentuated when no gauge glass is used, and the feeding has to be absolutely independent of the driver. The oscillation and vibration of the car make it difficult to read the gauge glass unless it is very close, and at high pressure we certainly consider it dangerous. Its use also necessitates the boiler being inside the body of the car, and this is objectionable, and for the carrying of some goods may be very detrimental. Moreover, to comply with our condition that no large volume of water should be constantly present in the boiler meant a very steady and continuous feed. We started by constructing a trial boiler, to find out a suitable feed-control gear, and to get data as to steaming power, time for raising steam, and fuel consumption. It was built up of 36 tubes, bent into grids, and coupled with small bolt flanges to a cylindrical phosphor-bronze water-drum 1¼ inches dia. internal and a ditto steam-drum 5 inches internal. The tubing used was solid drawn seamless copper, ⅜-inch o/d $\frac{1}{16}$-inch thick. This boiler had 33 square feet of heating surface worked at 200 lbs. pressure, occupied (the generator only) 2′ 6″ × 1′ 9″ × 1′ 2″, and weighed 180 lbs. It was, of course, intended to use a condenser with this boiler, but owing to the difficulty of finding room in an unroofed car, such as we built for our experimental work, we had to abandon all idea of using a condenser, and therefore this boiler. But even had we used a condenser the boiler was much too delicate to comply with the conditions we wanted, although it gave some interesting results in an experimental casing. It would evaporate nearly 100 lbs. more water per hour than its own weight at 150 lbs. pressure. Steam of 100 lbs. pressure could be got from all cold water in 5½ minutes by dipping the lighting wood in petroleum and feeding the fire carefully. It several times stood 400 to 500 lbs. pressure without a tube or joint going, and on the various occasions when we ripped tubes open by using excessive pressure or neglecting the feed, absolutely no trouble or danger was caused.

Boiler II was made in order to use less pure feed water. Straight tubes of ¾-inch bore were expanded into boxes, with lids at the back, practically identical with those used by Gurney. The water and steam drums were practically as in Boiler I, only split longitudinally like Yarrow's water drums to get to the tubes for removal or expanding in place. This boiler was built up by giving each row of tubes an upward rise from the water drum of about 15 degrees, being, in fact, evolved from the grids of our first boiler with the boxes substituted at the bends to get the accessibility mentioned above. This boiler gave very good results indeed, but an accident to the feed supply started the water-box joints leaking through, as we concluded, the iron bolts stretching with the overheating.

Boiler III.—In order to reduce cost and weight, for these individual boxes were both costly and heavy, and to obviate this trouble with expansion in the bolts, split phosphor-bronze drums with phosphor-bronze bolts were substituted. This boiler when tried in a brick casing off the car gave very good evaporative results. It weighed (generator only) 280 lbs., had 33 square feet of heating surface, and occupied about the same space as Boiler I. Its evaporation over eight hours averaged 270 lbs. per hour at 150 lbs. pressure, thus giving nearly 9 lbs. per square foot of heating surface, and 8·3 lbs. water per lb. of gas coke from and at 210°. We shovelled coke into the fire box, filled up the water tank, and regulated the flow of steam, approximately to ordinary road conditions, for eight hours continuous steaming, but had no gauge glass or other indicating gear to show the water level. This boiler was then placed in the car, and although the car was fitted at that time with pneumatic tyres the road vibration turned the boiler into a sieve. This left us in the position of debating whether it would be possible to make this type of boiler to stand the vibration of rough and smooth roads, for every trial we made gave us the same result. Joints that were good and sound in the shop simply shook to pieces at once on a bit of Lancashire road. Although we are forced to deal cursorily with these boilers each one occupied several months in making and trying, and each boiler was modified and remade several times. Metal to metal joints, soft copper ring joints, and asbestos thread joints were all tried. So much so that, although by this paper we only made five boilers, we believe that in the two years we have tried 16 or 17 differently made forms of these boilers. We show you here a sample of one of the drums, and in every case each boiler was hydraulically tight at double its working pressure. We decided to give up bolted joints, and copper, and phosphor bronze, so designed, and put in hand

Boiler IV.—This was to be made throughout of steel; solid drawn steel tubes to be expanded into connecting boxes machined out of steel bar, and the top and bottom rows expanded into solid drawn steel water and steam drums. There is very little doubt that this would have made an excellent and very strong boiler, but when about half way through it we decided that the enormous amount of work it involved and its consequent cost would preclude its being successful for autocars, from a commercial point, even if it were

* Excerpt of a paper read before the Liverpool Centre of the Self-Propelled Traffic Association, February 22nd, 1898, by D. H. Simpson and W. L. Bodman.

thoroughly satisfactory in its working. We show you here one of the connecting boxes of this boiler.

Boiler V.—We turned our attention to a different type of water-tube boiler, that is the so-called—but as we think miscalled—instantaneous generator of the Serpollet type. We think this boiler is a good deal misunderstood, the usual idea being that a series of tubes are placed over a fire, heated up to a red heat, and a little water injected into them, which is made then and there into steam, passes through the tubes and into the engine. This would subject the boiler to excessive wear due to the high fire heat, and the engines to a course of burnt oil and cylinder walls. As a matter of fact the process is in actual working very normal. The temperature of the last tube is only that of the issuing steam, usually about 500° F. The flow of steam is quite regular, and stopping the withdrawal of steam only gradually increases the pressure. Always that is provided the boiler possesses the essential features of a proper working "flash boiler." These are:—

(a) A restriction of the passage to bring the water into intimate contact with the heating surface, and prevent "gulps" of water passing through surrounded by steam.

(b) Adequate weight of metal to replace the volume of water necessary in an ordinary boiler to allow for fluctuations of work by absorbing heat.

(c) Ample capacity to avoid working too near the corresponding temperature of steam at the working pressure, *i.e.*, working with too little superheat.

(d) In case of excessive overheat after a long stand either all joints, piping, engines, &c., constructed to stand the superheat, or means used to regulate and reduce the temperature of the steam to within reasonable limits.

This type of boiler has only been possible of construction since the manufacture of solid drawn steel tubes; welded tubing will not stand the treatment necessary to constrict the passage or the subjection to high fire heat without splitting. The best known methods for constricting the water passage are the well-known crescent of M. Serpollet, and the round tube with a core. We decided to try a method, novel in its application, to flash boiler tubes, but well known as a very successful surface for heating by steam in feed heaters and calorifiers. This is the "Row" patent indent, in which the tubes are pressed between dies alternately at right angles, giving the tube a peculiar "wavy" shape, causing the fluid passing through to come into most intimate contact with the sides, and to get most thoroughly broken up for the absorption of heat. Experimentally to try this boiler and get at the most convenient and correct size of tube we made several boilers varying in the bore of tube from ½ inch to the present tube shown you here.

This boiler, VI,* is the last we have made, and the one we are now trying. The tubes are of solid drawn steel, with the ends swaged down, making them practically very stout double-ended gas bottles. Twenty-two of these constitute a boiler for the evaporation of about 300 lbs. of water per hour. They are coupled in series over the fire, being connected by steel tube bends. We would call your attention to the joint used, as it has a great variety of uses, and is of immense power. The ends of the main tubes are screwed 11 to the inch, and off the bends 14. A strong hexagon nut screwed to fit the bend at one end and the tube at the other is used to draw the bend up the tube, the difference in thread giving a pull equivalent to an ordinary union nut with 51 threads per inch, and the strength of 14. Forty-four joints rung up with this joint stood 800 lbs. hydraulic test, at the first time of screwing up.

The generator, as composed of steel tubes of special shape, is placed in a suitable casing over a fire. Connected to the steam outlet is a double-ended steel gas bottle, which has a tube passing through its centre, through which the feed water from the pump passes on its way to the generator, and is thereby heated, removing some of the superheat of the steam, and by the introduction of hot water increasing the duty of the boiler. Also after standing or when the steam is very hot, water is sprayed into the drum, and is evaporated by the extra heat of the superheated steam and passes on to the engines.

This system of injecting water into the steam and cooling it down to a reasonable temperature, *still leaving our boiler hot as a reserve of heat*, we consider overcomes one of the greatest difficulties of this type of boiler.

The method of starting and working will be clearly understood by comparing the diagram with the following:—The generator is raised to a black heat, say, 800° F. A stroke or two of the hand-pump, HSP, sends the water up the pipe, PD, the injection valve, ISV, is opened, and a small amount of water allowed to enter the drum, ID. The valve, ISV, is then closed, and the water travels through the feed heating tube, FHT, in the centre of drum, ID, and on through the feed pipe, FP, into the generator. The superheated steam then passes into the drum, ID, where any excessive superheat is extracted by the feed water passing through the central tube, and by the water injected into the drum.

The hand pump is worked until the water relief valve, SPV, which is set to working pressure, starts returning the surplus water to the water feed tank, FWT. Then the main stop valve, MSV, may be opened, starting the engines, which work their own pumps, EP, keeping up the supply of water, any surplus being returned by the relief valve.

Feed Water Control.

The following is a brief table of the different methods used at various times to control the feed water supply to our water-tube boilers without using any automatic gear:—

(a) Pump worked off crank-shaft calculated to give about average requirements:—To regulate this the small injector shown was placed at the water level. If the water was low the injector sent some in until it rose to the level of its steam-pipe when water was returned through the overflow to the tank. This failed chiefly because the returned water overheated the water in the feed-tank and caused trouble with both pumps and injector, and the steam was also too wet taken at such a low level for the injector.

(b) Pump off the crank-shaft, feeding through a live steam feed-heater, the steam-pipe of which was taken from the water-level, and any water that came over discharged by a steam-trap back to the feed-tank, injector taking steam from higher up the drum. Trouble was experienced with trap and injector.

(c) Was a thoroughly reliable method. An independent duplex steam-pump was used—steam taken from the water-level passed through a live steam feed-heater and through the pump, the water from the pump exhaust being drained back to the feed-tank. Its fault was the excessive quantity of steam it used, equal to 30 per cent. of a small boiler evaporation, which was thus reduced to about 6 lbs. per pound of fuel. Numerous modifications of these were tried, but in substance these were our main systems of feed control.

Engines.

The chief feature in the design of our engines has been the use of bored guides, ball socket bearings, and any other device that would enable the engines to run under bad conditions of twist or wind in the framing. It will be seen from the photograph that no bed plates are used, the engines being hung directly to the tubes of the car perch framing. On one occasion, through an accident, the main tube of the perch frame was bent down 1¼ inches, giving one engine a bad twist, but, nevertheless, it worked for several days without perceptable trouble. Ordinary curved slot double eccentric valve motion was fitted. Our first intention was to work compound with either total simpling and facility for working both engines at high pressure, or to increase the starting pull by admitting high pressure to the low pressure only.

We determined to make every possible effort to avoid using gearing of any kind, so our first car was designed with only 32-inch driving wheels, the crank-shafts being forged solid with the wheel hubs, the high-pressure engine on one wheel, and the low-pressure on the other. This, at 12 miles per hour, only gave us an engine-speed of 126 revs. per minute. We anticipated trouble at slow speed, due to the unequal power on each side of the car, but at a speed as low as two miles per hour the motion was perfectly steady. The low pressure cylinder, if in a favourable position, could always start the car, but if this was on the centre the small high pressure engine was unable to do so. Moreover, we found that, as often happened in our experiments, compounding and simpling is an amazingly easy thing to arrange on paper, and for nearly all other work is correct enough, but on the car it was extremely troublesome, involving a number of connections and a liability to fluster a driver working in traffic, the very place where frequent starting and stopping made simpling of most value. So we removed our high-pressure engine and put in another identical with the low-pressure and worked both at high-pressure, still preserving independent direct driving.

These engines could in almost every conceivable case start the car—if not forwards, a yard backwards was sufficient to get into

* We illustrate this boiler in our present issue.—ED.

R 3

a positinn to go ahead. As was to be expected, we had several mechanioal faults in this system. Our engines were too short in stroke, and tbe crank-sbafts too weak to sustain the car load, and frequently closed, binding the connecting rod brass; but we certainly concluded that direct driving is a possiblo and paying system for all loads under 1 ton gross that require transporting at high speeds. One combined starting handle and the steering handle is all the driver bas to attend to—no transmission gear, beautiful on paper, but a horrible *bête noir* in practioe, to arrange on a spring suspension, and always liable to derangement by dirt and dust. The only penalty is a higher steam consumption, somewbat larger engines, and, consequently, slightly more boiler. But in dealing with the small load (*i.e.*, say four to six persons) mentioned above, the percentages of these increases is so small that tbe increase of fuel cost at the rim is practically nil; whilst the saving in primo cost and repairs over a heavily-geared car such as seems most fashionable would, in our opinion, certainly equal 5 per cent. and 5 per oent. per annnm respectively.

Our next trial was to obtain data for heavy loads, and we proceeded to develop our dog-cart phaeton into a small lorry, such as you see in the pbotograpb. We replaced the 32-incb driving wheels with wheels 50 inches in diameter, working on an ordinary Collinge patent axle, and preserved tbe whole of the under-frame of our previous car without alteration. In order not to necessitate too much alteration, we only geared 4 to 1, and even at that bad to drop our machinery, as you will see in tbe photograph, a great deal too near the ground fnr proper practice. In the case of a light car and load it is evident tbat, should the engines botb be on their centres, it is not muob trouble to pusb the car a little to get right for starting, but in the case of a heavy load this would not be possible. We were, bowever, determined at all costs to avoid "jack-in-tbe-box" gear, whieb is liable to get a twist and fire, is heavy, and is not by any means efficient in transmitting tbe power on corners. Manœuvring in difficult places will bo of the highest value in goods work, and we arranged our engines to work as follnws:—The pinion on the erank-shaft of eacb engine is driven by a plain claw clutch sliding on featber keys. Tbe sbafts of each engine are independent, but come together in the middle of the car, where tbe two halves of a two-claw clutch slide on feather keys on eacb shaft. The two halves of the clutch are so placed on tbe sbaft that they only fall into gear when the crank of the engine are at right angles. The chain wbeel clutch lever and middle olutcb lever are coupled together each to eacb on both sides, and by means of tbese three plain claw clutches fnur differsnt operations oan be accomplished:—

1. Each ohain clutch in gear and centre clutch out gives each wheel a separate engine and plain, independent driving.
2. Near-side cbain elutcb in gear, centre clutch in gear, off-side clutch out, and road wheel running free, gives a big effort to belp the car to start sbnuld the wbeel be in a hole or starting on a curve from left to rigbt after standing, say, in a bay or hovel. Both engines being coupled togetber at right angles insures certainty of starting.
3. Off-side ehain clutch in gear, centre clutch in gear, near-sids clutch out of gear, road wheel running free. This gives a similar motion to No. 2 position, but for the opposite wheel and curve.
4. Near-side chain clutch out of gear, centre clutch in gear, off-side cbain elutch out of gear. This position leaves tbe engines disconnected from the road wheels, coupled at right angles, free to be run light, for warming them up, pumping water into the boiler, or doing nutside work, such as driving a small dynamo, pump, &c.

By means of this comparatively simple mechanism we do away with friction clutches, countershafts, and differential gear for turning corners, as in no case can the two road wheels be coupled together, they either each havlng a separate engine each to each, or one two engines at right angles, and the other wheel free to revolve.

In driving the car we work onr engines both on the throttle and notched, a tbrottle valve being coupled to the reversing shaft, which shuts steam off from tho engines in mid-gear, and gradually opens as the lever is moved over from mid to full gear.

Construction of Car and Framing.

Apart from their uses, road vehicles may be roughly classed as perch suspension and plain suspension vehicles. In a perch carriage the power is transmitted to the rear wheels directly from the foro carriage to the hind axle without the necessity to pass through the body and springs, and this is the proper and most mechanical method. The simplest fnrm of perch is a plain timber oarriage, and tbere seems to bo a general concensus of opinion tbat, even when this perch is not used as a frame to carry the driving machinery, it will be the best suspension for autocars as offering tbe most rigid drive from axle to axle.

In our case we have made the perch very pure in its construction, the rear axle being rigidly attached to it, and the fore axle being directly attacbed to the peroh tube through a central bush. This axle is thus absolutely free to play as an oscillator without any spring restriction whatever. Tbe tnbes of tbe perch carry the engines, so that our chain-gear wbeel-centres are rigid and do not vary. Our earliest boilers were also placed on this perch, but as they made such a large percentage of tbe total dead weigbt, and materially affected tbe draught, we bave since placed them on tbe spring portion or body of tbe car. We have made every attempt, and shall continue to do so, to keep the boiler at tbe rear end of the vehicle and absolutely below it; and as a general rule, it may be taken that this will be our lines of arrangement, subject to slight individual modifications in the body of the vehicle:—Perch suspension, the engines being carried iu the perch frame. Frout axle absolutely free to oscillate about its centre. Short wheel base to facilitate turning (our present miniature lorry is 10 feet 3 inches long, with a 4-foot 3-inch wheel base). Boiler at the rear, eutirely below the platform or bottom of vehicie; water tank in front of boiler, fuel reserve in front of tank. The whole of the platform is thus clear except for the flue at the extreme rear. This fits in a socket to lift away for loading with a jib crane. The driver sits on the platform at the off side with a small footboard hung in front, and takes up comparatively little room. All this necessitates the platform being somewhat high from the ground; 4 feet 6 inches would be necessary if the boiler is solid fuel fired and absolutely beneath the platform witbout auy raised part as in the photo shown here, but we certainly cousider that 9 inches absorbed here is better tban taking up 4 or 5 feet in the length of the car. Moreover, this method of using the whole area of the car for dead load allows a builder to arrange his weights with great nicety, and keeps them all low down for stability. Metal *v.* Timber construction will have to settle itself by a judicious amalgamation of tbe virtues of botb systems. It is possible that we can claim to have been the only people to ever design and make a car tbat was entirely metal even down to the spring blocks. This was a "four-wheeled dog-cart," carrying four passengers, and, although coustructed entirely of Mannessmann steel tube, it followed the lines of an ordinary pbaeton very closely. We used it for tbe trial of nearly every boiler we made, and it would have been used by us for the present series of experiments but that we found ourselves so cramped for room in it that the smallest alteration in connections or arrangements involved very tedious work.

The advantage of metal construction for road vehicles is the possibility it allows for absolute interchangeability, enabling repetition work to be dono to absoluts standard, and its comparative indestructibility. But it is undoubtedly more expensive; it is very difficult to joint, so that the range of designs available is very limited; it acts badly under vibration, easily takes a set if too beavily loaded locally, and for equivalent loads is certainly heavier than timber. This last statement will be accepted with reserve, but up to the prssent we have drawn designs for several lorries and vans of size available to work the heaviest loads, and using tube, H, aud timber constructions. In all cases the timber allows a decided saving in weight when carefully calculated up. If anyone desires ossily to prove this he has only to draw out a wooden oak and ash-built wheel, say 3 feet 6 inches high, with 4-inch spokes and 6-inch by 1-inch tyres, the whole suitable for a very heavy lorry, using 3-inch drabble arms for axles. Then let him design a metal wheel capable of doing absolutely equivalent work with renowable tyres and renewable axle boxes, he will find, whether he uses steel disc, H or T iron or tubular or solid spokes, that his metal wheel is cousiderably the heaviest. It must be borne in mind that in practical lorry building the suspension, &c., necessitates a large number of parts being affixed to the frame, aud a fair width of bearing becomes needful. This the timber framing supplies, but to get it from a metal one often means the use of a heavier section than is needful so far as the strength, &c., is concerned. We bave come to the conclusion that timber framings, judiciously edge-plated or "flitched," will enable lightness to be obtained, with the needful accession of strength tbat the narrow "long-backs" of the "Act" will necessitate if very bulky loads are to be carried on steam lorries. The metal tubular construction necessitates a very costly joint and metal H ditto a very beavy joint as well as being fairly costly.

Steering will be a matter that, in reference to heavily-loaded cars, will require a great deal of experience before it can be said to be satisfactory. We, ourselves, think that jaw axles are the most suitable for self-propelled work, admitting of an easier, freer design to the front, a perfect oscillation to the front axle, and differential locking which is very valuable on wet ground.

We have made a hydraulic steering gear to test, as being very powerful for heavy loads. We have not given it up to the present any very extended trial, for on our extremely short wheel base it was too sensitive and turned us too quickly for regulation. Of course, the bath chair handle style will not be powerful enough for loads, and we use at the present time a worm gearing of six to one, and a chain gear that again multiplies the power. This is sensitive enough for a child to use when the car is in motion, but it will hardly stand the strain of locking the wheels when standing, as a driver might want to do to get out of an awkward corner.

Brakes, although important, are not nearly the momentous question on a steam car that they are to users of oil-motors. In his reversing gear a driver has the finest stopping appliance that he can want, and this reason has influenced us in making the reversing lever the primary driving handle. If, in addition to this, he is provided with a good stamp of foot brake he should be able to hold his load on the descent of any hill that he can mount. We have had a hydraulic brake on our car, and in practice, as it is a very cheap brake to apply, it could readily be fixed for emergency work and to comply with the Act.

Fuel.

The fuels available for steam lorry boilers are :—

Lancashire Gas coke	averaging	6*s*. per ton.
Furnace coke	"	15*s*. "
Anthracite	"	23*s*. "
Tar and crude oils	"	30*s*. "
Petroleum	"	90*s*. "

We have obtained as good steam results from gas coke as from furnace coke, but it is of very varying quality, and it would be almost impossible to use it on the road owing to clinker and dirt. Anthracite is as costly here as in London. Furnace coke seems to fulfil every possible condition that can be required from solid fuel. Clean to handle, easy to obtain, works at a cost slightly less than 0·5*d*. per ton-mile of load, absolutely free from dirt or clinker, does not require anything excessive in draft, so that the flue nozzle can be kept very silent. We made a number of experiments to burn liquid fuel. The sole value of liquid fuel in goods work would be its convenience, and it is almost impossible to overrate the value it would have in that respect. It saves from 150 to 200 lbs. in the weight of the boiler case. It enables the boiler case to be one-third shallower in depth. It enables one to force the boiler under stress of load in an exceptional degree. It is not bulky to carry. It is easy to obtain *en route*. But its disadvantages, we came early to the conclusion, absolutely damn it as a fuel to burn on vehicles at present. Its noise, when burnt in any quantity exceeding one gallon per hour, is absolutely intolerable. Its absolute unreliability under the slightest change, often quite imperceptible, of circumstance in atmospheric condition. The unpleasantness of handling it; and, finally, its cost.

Vaporisers.

Vaporisers may be dangerous and certainly necessitate the use of cleanly and, therefore, comparatively costly oils.

Atomisers are forced to be so small in aperture that they easily gum up and knock off.

Necessity for Additional Pumps and Connections.

It does not seem to have occurred to many people that the use of petroleum in vaporising burners is really equivalent to establishing another small boiler, with all the needful control gear, piping, &c., and working a fluid that in the event of a burn-out of the vaporiser becomes a danger.

One of the weak points of a steam-car is the piping and joints, and it is no recommendation to a system of firing that all these are duplicated in a small size of pipe that is always troublesome.

The comparison of cost is easy. At the best liquid fuel cannot, if it is a clean oil suitable for vaporizers, be bought at less per pound than seven times the price per pound of furnace coke, and it cannot in practice be made to do better than three times the evaporation of coke, so that it must be in working double the cost. There is the claim that when shut down for standing it saves, but the claim will not hold water. Tar or crude oil, worked in a spray or trickle burner, is as cheap as solid fuel, but it must be warmed and has a terrible knack of clogging, of suddenly varying its flame and sending over dense smoke, and behaving generally badly. Still, with all these disadvantages of cost and trouble, if only the noise of burning could be absolutely prevented, we think it would be the preferable fuel, solely for the convenience it gives in the design of the boiler-case and in stoking.

The commercial points of a self-propelled vehicle that an intending user should require are, in our opinion, and as the result of careful consideration :—A prime cost about equal to three and a half times the prime cost of a horse-lorry capable of moving the same load with all its horses and appointments ; a depreciation account and repair bill not exceeding 33⅓ per cent. per annum of the prime cost, to keep it always in the highest condition; an attendance and driving that does not exceed his horse-lorry for wages, or but very slightly; an utter absence of all refinement in feed, driving, and steering gears. If he obtains this, and can so arrange his work that the lorry is in fairly constant employment, he will on these charges effect a most substantial saving over horse traction. The greatest economy will be effected through the maintained speed that he can get; more especially is this marked in the lighter lorries.

The conclusions we have come to as to the commercial future of self-propelled vehicles for goods and general traffic are somewhat at variance with those generally held, and they may be interesting to you. It is usually accepted that the heaviest load that can be carried will, by its reduction of the wages item and the fewer number of cars necessary, work out most successfully. This is not wholly our opinion, which is that the item of speed is of paramount importance to load, provided that a correct mean is found. Thus a lorry carrying 1 ton can probably be forced to an average of 12 miles per hour, equalling 12 ton-miles of load per hour; one carrying 2 tons to 8 miles per hour, equalling 16 ton-miles; whilst a heavy lorry carrying 4 tons could not exceed 4 miles mean speed, equal to 16 ton-miles per hour. By this the 2-ton lorry should be able in the working day to nearly equal its heavy rival. We will not consider it in relation to anything capable of shifting more than 4 tons of load, as we should just like to see such a vehicle built and at work. Such a lorry as a 2-ton lorry, working at 8 miles per hour, is a feasible vehicle, and its use would possess many advantages over a heavier class :—Smaller units, less light load work, and great convenience of handling either in bad places or in a breakdown; the high speed would enable much longer journeys to be undertaken inside an ordinary working day—as, say, 30 to 40 miles each way; less capital is idle during repairs; greater safety in construction, as the builder would not need to work so near his factors of safety; less possibility of disagreement with local authorities; and, above all, the fact that resilient tyres could be used, and the risk and wear and tear of running enormously decreased. To find out the prime cost of such a vehicle, or rather to see the margin that a lorry user has to work with, we made the following comparisons, worked out at the highest limit in all cases; but we have taken the 2-ton lorry as only having a mean speed of 6 miles per hour, although we think that in practice it will be easier to run such a lorry at 8 miles per hour than a 4-ton lorry at 4 miles :—

A horse's capacity for work is as nearly as possible the equivalent of 36 ton-miles per day for 300 days per annum. Of this it will be found that whether he works alone or in company with another approximately one-third is tare work and two-thirds, or, say, 25 tons per day, is load. 1 horse work = 1 ton tare, 2 tons load, at 2½ miles per hour, for 5 hours' actual working per day = 25 tons per day for 300 days per year = 7,500 ton-miles per annum. The horse cost alone per ton-mile of load should work out about 2*d*.

Cost of horse, say, £60.	£	*s*.	*d*.
Interest on that	3	0	0
Forage, at 12*s*. per week	31	4	0
Depreciation and repairs	15	0	0
Shoeing, at 5*s*. per month	3	0	0
Rent, rates, taxes, &c., 3*s*. per week ..	7	16	0
Harness (2 years' wear, at £6 10*s*. per suit)	3	5	0
Rugs, &c.	1	10	0
For 7,500 tons of load	£64	15	0

The lorry cost should work out at 6*d*. per ton-mile.

Cost of lorry, including sheet, say, £45.	£	*s*.	*d*.
Interest on that	2	5	0
Depreciation and repairs, 25 per cent. ..	11	5	0
Housing, &c., 2*s*. per week	5	4	0
For 7,500 tons of load	£18	14	0

Actual labour cost alono per ton-mile = 2·5*d.* per ton.

Man at 24*s.* per week, boy at 6*s.*, £78, = 2 + 6 + 2·5 = 5·1*d.* per ton-mile, as the total cost.

The working capacity of an equivalent steam lorry would be 4½ times as great as this.

Steam lorry weighing 2 tons, load 2 tons, speed 6 miles per hour = 12 ton-miles of load per hour for working day of 10 hours = 120 tons per day = 36,000 ton-miles of load per year of 300 days. That is to say, that if work could be arranged to keep the steam lorry constantly at work for that period it would displace annual charges = £765. Now several of the charges of such a steam lorry doing that work can be accurately given.

	£	s.	d.	
Wages—Man and boy, 34*s.* per week	83	4	0	
Fuel at 6 lbs. per ton of load per mile = 100 tons	75	0	0	A.
Water at 1*s.* per 1,000 gallons at 30 lbs. per ton load	5	8	0	£92 18*s.* 0*d.*
Oil at one-sixth of fuel	12	10	0	
Lighting, 18 lbs. wood per day, at 10*s.* per ton	1	4	0	
Licence	2	2	0	
Housing, at 3*s.* per week	7	16	0	
	£187	4	0	

This leaves £578 4*s.* to cover the two items of interest and depreciation, which, at 5 per cent. interest and 25 per cent. depreciation, it would do on a prime cost of about £1,935. Of course, the probability is that not more than 50 per cent. of the horse load could be arranged to be conveniently done by the power lorry, which would give £967, plus one-half of the running charges in items A, viz., £46 9*s.* = £1,013 9*s.*, as an equivalent cost price to horse-lorry work. But as £400 is quite a possible and reasonable figure at which these steam lorries for 2 tons loads should be produced, there should be, even after an allowance for higher attendance charges than we have given has been made, a substantial saving of at least £100 per year on each horse at work. The distance covered by such a lorry working at this pressure would be 60 miles per day.

In working a load of 2 tons tare, 4 tons load, with 2 horses at 2½ miles per hour for 5 hours = 50 ton-miles per day, or 25 per horse of load—

		d.
Cost for horses per ton-mile of load	=	2·0
„ lorry „ „	=	0·3
„ labour „ „	=	1·25
		3·55 per ton-mile.

An equivalent steam lorry 3 tons tare, 4 tons load, working at a mean speed of 4 miles per hour for 10 hours, would have a capacity of 160 ton-miles per day = 3⅕ horse lorries displaced, or annual charges of £710. The annual charges of such a lorry, in addition to interest and deposit and repairs, would be—

	£	s.	d.
Man and boy, 34*s.* per week	83	4	0
Fuel at 6 lbs. per ton-mile; load 128 tons, at 15*s.*	96	0	0
Water at 1*s.* per 1,000 gallons, 30 lbs. per ton	7	2	0
Oil, &c., at ⅙ fuel	16	0	0
Lighting	1	4	0
Licence	3	3	0
Housing	7	16	0
	£214	9	0

Leaving £496 per annum to cover interest, deposit, and repairs before an equivalent cost to horse work is reached. As £500 is a possible cost for such a lorry, these items at 5 per cent. and 25 per cent. respectively, work out to £150 per annum, leaving £346 margin.

The following comparisons of work at 8 and 4 miles per hour will exemplify the meaning of obtaining economy by increasing speed:—Say a man has 8 tons to shift from Liverpool to Warrington, a distance of 16 miles = 128 ton-miles, two lorries carrying 2 tons each time could transfer the load and return in 8 hours. Two lorries carrying 4 tons each could only do the same. Double the length of the journey, say, Liverpool to Manchester, and it becomes too long for a working day for the heavy lorries, but four 2-ton lorries could do it and return finished in 12 hours.

Speeding to economise is the most modern practice, and we think that the less one regards this Light Locomotives Act as a means for substituting traction engines for ordinary horse work the better. If a load is so heavy in its single bulk that it cannot be safely carried on a 2-ton lorry, it becomes a subject for a traction engine; any goods that could be broken in bulk to transport speedily we believe it would be economical so to treat, and certainly in the early stages of this industry much safer.

The paper was illustrated by several photographs thrown on a screen by the oxyhydrogen light, with the aid of which Mr. Simpson pointed out details in the working of the machinery used in the various experiments, particularly in the later and more successful stages.

The Chairman (Mr. J. Brodie, M.I.M.E., &c.), said the best thanks of the Society were due to the gentlemen who had prepared the paper. It was a very valuable one, and these gentlemen had spent a great deal of time in investigating the subject.

Mr. Alfred Holt said the paper had given him great pleasure. It was evidently the result of very considerable experience, and the taking of a great amount of pains. He had before expressed the opinion that the solution of these questions was not so easy as some gentlemen assumed, and the lecturers in this paper acknowledge the great difficulties they had and have to face. He sympathised with them and heartily wished them success. I would like to make one or two remarks, which may, perhaps, seem irregular or disjointed. The paper says of the proposed power goods' vehicle, that "its prime cost should not exceed to the user three and a half times the cost of one horse lorry with its horses and appointments." In his (the speaker's) opinion that involved a capital cost which was rather greater than would be readily accepted by cart owners. He was, however, very much pleased to see an opinion expressed by the authors which he considered a very sound one, namely, that they had "decided to confine our researches to steam as a motive power." He would ask whether it was possible to make a vehicle suitable for this purpose merely by making two wheels revolve. He questioned it very much, and certainly the revolving of two wheels as aimed at by the authors of this paper. They had repeatedly seen lorries in the streets with two wheels fastened, with horses and driver holding back, and yet unable to sufficiently retard the progress of the vehicle without running the side-wheels along the kerbstone. He was afraid that any vehicle which depended only on making two wheels revolve, or preventing them from revolving, would be insufficient without a roughening of the tyre or the adoption of some mode akin to the cog action. With regard to the jaw clutch motion he would ask the authors if this was likely to prove a durable or lasting arrangement in the case of heavy loads. He was of opinion that it would be unlikely to stand. There was one point he noticed with pleasure. His experience on this point had quite upset his first theory, and he was glad to be supported from this independent source in the belief that a much stronger wheel could be made from wood than from metal. Wooden wheels, and even wooden driving wheels for locomotives were used on the first Lancashire railway, but these were discarded on account of their bulk, and because the heat from the engine affected them.

Mr. J. B. Corrie said the authors in their paper spoke of the burner clogging. He had some experience of burners, especially with the Holden burner on the Great Eastern Railway, which was that there was no trouble. It gave very excellent results, and the only thing that was objectionable was the noise. Then there should be no smoke with a triple burner, if it was properly regulated.

Mr. J. P. Lea (Manchester) said he wished to inquire as to the disposal of the steam. If it was condensed the necessity for a large supply of feed water was reduced. With regard to the form of the boiler one naturally thought of the question of the cleaning of the tubes, especially as they were so irregular in shape. Then he would like to know whether there was always a stated pressure in the boiler—whether the steam was exhausted down to one stated pressure. Then he was in doubt as to the way in which the mechanism actuated the wheels. He wished to express his thanks to the authors for giving them the results of what must have been expensive experiments.

Mr. E. Shrapnell Smith asked what was the total metal weight compared with the horse-power, and also referred to the exposure of the machinery to dust. He would like to have an explanation of the means taken to reduce the superheat. As hon. secretary of the Liverpool Centre he was glad to hear that they would have one of these wagons at their trial in May next, and for this and for the excellent paper he was personally much indebted to the writers of the paper. (Applause.)

In response, Mr. SIMPSON said they tried no definite make of burner, but if the makers of the Lucigen could produce a burner that was thoroughly satisfactory, and require no extra piping, they would be only too pleased to adopt it. In reply to Mr. Holt, he would say that the mechanical difficulties of driving each wheel of four were at present almost insuperable. Efforts were being made in France to do this, but they were not yet satisfactory. With regard to the adhesion question, nothing but practice would settle it satisfactorily. If the weights were heavy sanding would be necessary, perhaps, as it was now used to get a good start when the ground surface was greasy. The same remarks would, of course, apply to the question as to the use of brakes. With regard to spray burners they worked beautifully in climates like France and India, but it was different in our climate. They would, perhaps, work well when going, but after a stop—if only for a minute or two—they would not start even with a 100 lbs. pressure to the square inch. It seemed the oil passed through a peculiar gum action—a pin would remove the obstruction immediately. Even in a large orifice the effect was to close the nozzle. He agreed that the Holden burner was almost a perfect one. They had not the slightest difficulty in regard to the disposal of steam. In answer to the gentleman who spoke of the tubes, he might say that the tubes cleaned themselves. They were subjected to a temperature of 400°, and any deposit in the water was turned into fine powder, and carried off. The speaker here explained in detail the method of carrying off the superheat, and said that if the engine was stopped water was forced from the boiler, as the temperature rose, into the cold-water tank, so that they got a silent blow off. The clutch was not used in ordinary working, but only in starting. It was used to get the right position to start, to get the engines at right angles if they happen to be both at dead centre at the same time. He could not give proper data as to weight of motor as to car. As near as he could say, the boiler would weigh 10 cwt., the engine gearing about 3 cwt., and the total weight of car 30 cwt., to carry 30 cwt. or 2 tons. With regard to their last boiler, they had experienced nothing but satisfaction. It worked thoroughly satisfactorily.

The proceedings then terminated.

In deference to the wishes of several members of the Self-Propelled Traffic Association an adjourned discussion on the paper took place on March 1st, Mr. A. Holt, M.I.C.E., presided.

The HON. SECRETARY (Mr. E. Shrapnell Smith) read a letter from Professor Hele-Shaw regretting his inability to be present. The paper they had before them was a most valuable one, not least on account of the account it gave of the failures experienced by the authors, which disposed hearers to accept with greater confidence the conclusions at which they had arrived.

The CHAIRMAN said this meeting was held at the express desire of many members that they should have an opportunity of discussing a valuable paper. (Hear, hear.)

Mr. BANNISTER said the paper was intensely interesting to him, as though he was more indirectly concerned in locomotive engineering and not a manufacturer of motor-cars, it was a matter of the greatest importance to help in any way in the development of this branch, which had for its object the transportation of produce from one part of the country to another. With regard to boiler conditions, while agreeing that an improvement in many respects was necessary to overcome the innumerable difficulties to be surmounted, he was of opinion that the real solution lay in the simplification and elimination, as far as possible, of mechanical details, rather than going in for the application of devices necessary in ordinary steam engine requirements. He did not agree that it was necessary to adhere to the existing type of car. He thought car and engine and all connected should be designed to meet the special requirements, and it should be designed as simple as possible. There should be few working parts—the fewer the better. The large number of cocks, valves, steam pipes, regulators, chains, and so on, which seemed to be in the present arrangement, should be eliminated as far as possible. This would be conducive to the betterment of the machine, and make its life longer. Even if this was done at a sacrifice of economy in fuel he thought it would be better so. (Hear, hear.) Of course, it was quite impossible to have a boiler of one single piece, but the joints should be so few and so strong that ordinary vibration should not cause them to leak. The tests should be very much greater than that given by the authors. He used very high pressure in his business, and he thought that even for ordinary land or marine boilers where vibration was normal they tested their boilers to eight times the working pressure. He thought the leaking of the boilers was due to the fact that they hung from the car, and that this could be overcome with a little—rather, he should say, a great deal of—trouble. His suggestions were made to elicit information from the authors. He wished to ask if it would not be possible to eliminate the drawing off of the steam direct from the boiler, and also the trouble in starting and stopping, whether they could not have some simple arrangement for water feed—two pumps for instance. He asked why the authors went to the trouble and expense of making headers when they could get those of Babcock and Wilcox, who stamped out their headers and worked their boilers up to 500 lbs. pressure—their headers being absolutely tight.

Mr. WHITE said he was sorry the authors had given up Boiler No. 4, which was an exceedingly good type, and he suggested that the expense could be much reduced if the joints were made by the hydraulic method used in bicycle tube building. The pressure, of course, would have to be correspondingly greater. He was inclined to believe that this Row type of tube would allow of a deposit, and otherwise it was an exceedingly good type. The question of feed for the boilers could, he thought, be easily settled. Suppose they put an insulated point which would touch the water when it rose to a certain point, and so be electrically connected with a smaller motor, which again would be connected with a throttle valve in the feed water. He was sorry they did not go in for roller bearings, which would largely reduce the power required to drive a motor. He liked the idea of the engines being coupled direct instead of through gearing, for it was necessary to eliminate the number of working parts as much as possible. He was also sorry they had abandoned the idea of a compound engine, which would allow them to dispense with a certain amount of gearing. Up to the present wood framing was better than tube framing, for you were more likely to get a good carpenter than a man who could put broken tubes to rights.

Mr. WEST said the authors had, in his opinion, chosen rightly when they stuck to steam. He hoped the authors would reap their reward, for they certainly deserved it. (Hear, hear.) He was glad to see that the authors laid it down as a rule that they would have the same amount of platform as the present. Then as to the demand that the speed should be twice that of a horse—that is, six miles—which, with heavy loads, was as much as they could hope to attain to begin with. The paper did not leave them hopeful for the future, for heavy traffic was spoken of as not likely to be much carried by this class of car. As long as they had a limit of three tons fixed by Act of Parliament as the basis of the tare of the vehicle he was afraid they would not go ahead as fast as they should do. There should be no limit, for the thing would cure itself. In some parts of France they had omnibuses which carried a large quantity of luggage and 14 or 15 passengers, and he thought there would be a future for a car here that would fulfil such functions as these. He was struck by the ingenious arrangement for the working of the wheels, and he agreed that wood was the best material for a car. Tubing was very light and strong, but liable to damage, which damage would be unrepairable.

Mr. E. SHRAPNELL SMITH asked if the authors, in their experiments, found "gulphs" of water surrounded by steam going through the tubes. The possibility was not such a remote one as might be imagined, because, as he had occasion to learn some months ago, water would assume the spheroidal form even at a temperature of 202°. With regard to the power excited in starting the engines and its effect, he said that at the moment you want the maximum effort they were limited to the adhesion of one wheel, or only one-fourth of the adhesion to be got out of the whole vehicle. Again, the machinery was attached to the perch without the use of springs, and this might account for the joints going as described. With regard to the comparative figures they could not be taken as absolutely correct, for modifications might have to be made. For instance, the paper spoke of the maximum work of a horse being 25 tons per day, whereas a master carter had assured him (the speaker) that many Liverpool horses did something like 48 to 50 tons per day. Yet the authors had undoubted authority for their statement, but in Liverpool the horses did more than usual. It was interesting to think that the use of 2-ton vehicles would greatly multiply the units, for supposing a load of 1,000 tons had to be carried between Liverpool and Manchester it would require 500 vehicles—or one every three minutes. He must, to a certain extent, combat the statement that four tons was as yet about as much as could be carried by a vehicle of about the same weight. He had visited the works of builders who were endeavouring to work out this problem,

S

and he had seen a motor-car weighing 2 tons 13 cwt. carrying four and a half tons of pig iron, and he had no doubt if the platform was larger a similar weight of other goods could be carried. The vehicle was decidedly noisy, and, comparing it with that of Messrs. Bodman and Simpson, it was not in the same street.

The CHAIRMAN, after expressing in his own name and on behalf of the Association their thanks to the authors, said the primary object of improvements in vehicular traffic was to cheapen the cost of transit, and this applied very forcibly to the case of Lancashire. The only argument the railways would listen to was that of competition, and so far they had punished Lancashire severely. He was convinced that Lancashire paid for half of the non-productive railways in the kingdom (hear, hear), such as lines in North and South Wales, Oxfordshire, and other places. Referring to the subject more immediately before them, he agreed that steam was the best motive power.

Mr. SIMPSON, in response, said they had always endeavoured to get as simple a boiler as possible. Their tests for the working pressure were only limited by the capacity of their testing pump, and they would in future test up to 1,000 and 1,800 lbs. for a working pressure of 250 to 300 lbs. With regard to the regulation of the feed water, it was far simpler to regulate the supply by a stop-valve, as in the Serpolet, than have it fed automatically, which would necessitate a gauge-glass. In the Row tubes they interposed a series of bafflers. The water came round the sides of the tubes, and not through the middle. There was no deposit, and, besides, the high temperature turned what might be deposited into a fine powder, and it was easily blown off. No. 4 boiler would be an undoubtedly good one, and the hydraulic method would be beautiful and thoroughly practical; but there was a difficulty of repairing in actual work, which militated against the adoption of this plan. Roller-bearings would be a great saving, but they were in an experimental stage, and it would be an experiment to adopt them.

Some Points in the Design of Automobile Vehicles intended for Heavy Traffic.*

(*Continued from p.* 193.)

Dimensions, &c.—These are partly fixed for us by the Act, which says that the outside breadth shall not exceed 6½ feet. We then have the Self-Propelled Traffic Association stating their requirements, viz., that the height of the deck shall not be more than 4 feet 3 inches nor less than 3 feet 9 inches, and also that there shall be 110 square feet of surface. Allowing a space of 5 feet for machinery, &c., we find that the overall dimensions must be 22 feet long by 6½ feet wide. In order to stow 7 tons of American cotton on this deck-space of 110 square feet, there would be 32 bales, each 490 lbs. weight, and each occupying 31 cubic feet; the pile would be 9 feet high, and, taking a mean height of deck of 4 feet, the top of the pile would be 13 feet from the ground. A longer car would be preferable for many reasons but, as we shall see, the Act penalises good design through weight. A longer car means much greater weight in order to obtain the necessary longitudinal strength.

Gauge.—An important matter is the gauge to adopt. I recommend the ordinary railway gauge, 4 feet 8½ inches, because in this city the streets are laid for the tramways to this gauge, and alongside the docks and warehouses we have a sunk railroad. There, in effect, plateways must be utilised by automobilists to their fullest extent No doubt the tramway and railway companies will hardly appreciate the intention of using their property in the way suggested; but the Act does so little for us, and the automobile vehicle is regarded by many as a kind of mechanical Ishmael, that we must make the most of our opportunities in every direction. By making use of these tramway and railway lines we reduce the resistance per ton to about 25 lbs., and the B.H.P. required to propel our car, weighing 11 tons, at five miles per hour, is but 3·7, or say 4½ I.H.P. This reduction in H.P. shows the great advantage of platewsys such as suggested by Mr. A. Holt.

Framing, &c.—For the framing we should employ nickel steel channels. In order to determine the least section, and therefore the least weight, we consider the weight of the load as 7 tons and the weight of the machinery as 1½ tons, or 8½ tons in all; this is 2¼ tons on each girder. We regard each girder as being supported at two points 15 feet apart (the wheel base). We also assume the load to be uniformly distributed over this length, and to be 28 lbs. per inch.

Employing the usual formulæ and a factor of safety of 3, we find that channel sections, 4″ × 3″ × 3″ × ·3″, are amply strong, this section weighs 12 lbs. per foot. Did we use steel we should have to use a 5″ × 3″ × 3″ × ·5″ section, which weighs 16 lbs per foot. Thus by using nickel steel we effect a saving in weight of 25 per cent. The framing would of course be strengthened and braced by diagonal and transverse ties; it would have a flooring or deck of 1½-inch elm, and its total weight would be 1,300 lbs.

Tubes v. *Channels.*—Here it may be well to allude to the growing tendency with automobile vehicle-builders to use tubes for framing, under the idea of obtaining strength. For purposes, as in cycles, where the stresses are mainly of a tensile or compressive nature, tubes are unquestionably the right things to use, but for heavy wagons the stresses are such as induce bending. In order that a tube shall be as strong as a beam, we must make the moduli of their sections equal; that in order to have a tube as strong as the girder above mentioned we must make, adopting the usual nomenclature—

$$\left(\frac{BH^3 - bh^3}{12}\right) = \frac{\pi}{32} \cdot \frac{D^4 - d^4}{D}.$$

Working this out, we find that the external diameter of the tube must be 6 inches and the internal diameter 5·65 inches, and the weight of such a tube is 11·7 lbs. per foot; its thickness being but ·175 inch, or less than $\frac{3}{16}$ inch. There is thus an apparent advantage in using tubes; but while the tube is structurally strong it is locally weak, and such a tube would be easily damaged. On the other hand, by making them thicker and heavier, they would stand having external connections made, and the tubes would form excellent feed or oil tanks. There is thus a good deal to be said in favour of tubes. For such very rough and heavy work as is here proposed I think channels are preferable.

Wheels, &c.—We now have to consider the method of applying the wheels. In ordinary wagons the axle on which are the wheels is secured to plate springs, which in their turn are attached by links to the framing. For wagons this method, which is in almost universal use, is no doubt as good as can be devised. In automotor vehicles we see that this method is also adopted—wrongly, as I think, because a little consideration will show that in any automotor vehicle the reaction of the forces, when the wheel is being forcibly moved, tends to move the axle in a longitudinal direction, also the gearing tends to the same end. Hence in locomotives it has been found essential to prevent any such action, and so the driving axles are held in bearings or boxes which are maintained in position by horn plates and all fore and aft motion entirely prevented. This system, I think, must be followed by us. As regards heavy automobile wagons there can be no question of the propriety of this. I therefore suggest the fitting of horn plates similar to those used in railway passenger or goods cars. Those horn plates would weigh about 41 lbs. each. The axle boxes would be fitted to them in the usual way. Instead of using the heavy plate springs which are so generally employed, I propose to use either spiral or volute springs in conjunction with indiarubber plate springs. Such springs would deflect more and weigh much less. The plate springs weigh, in fact, three times as much as a spiral spring, and only have a range of deflection one-sixth of the latter. For the axles I propose to use Mannesmann steel tubes. The excellence of the manufacture is too well known to need any description. This Mannesmann metal is a high grade brand of Swedish steel. The wheels would be made of mild steel of T section, 5 inches wide, the spokes would be also of mild steel, the hub would be a Mitis metal casting, each wheel would be 36 inches diameter, and would weigh 200 lbs. The fore part of the wagon would be carried on a pivoted bogie as is the usual practice.

A few remarks about wheel tyres may here be made, as this is a matter of very great importance. The width of the tyres has so far been settled by purely empirical rules Sir David Salomons states that a 3-ton vehicle should have 4-inch tyres. Other authorities say that the width should be 1 inch per ton. Obviously the width will vary directly as the weight, and inversely as the hardness of the ground, and also inversely as the diameter of the wheel. As regards the weight, this is practically unimportant in streets so well paved as those of Liverpool and other large cities, and loads of 9 tons per square foot, such as can be safely borne by rock or other substance, can equally well, and even better, be conveyed over granite setts on concrete floors.

In the country with good macadam roads it would not seem possible to impose greater loads than 3 tons per square foot of area. Now the area of contact between a wheel and a flat surface is

* Excerpt of paper read before the Self-Propelled Traffic Association, at Liverpool, on January 25th, by GEO. HERBERT LITTLE, Technical Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

theoretically a line. In practice it will be an area depending upon the diameter of the wheel and the nature of the ground. A wheel, 3 feet diameter, heavily loaded on a macadam road would have a length of contact of not less than 6 inches, or, for a four-wheeled vehicle, 24 inches in all; then in order that the area of contact shall be 1 square foot the width must be 6 inches; that is the 3-ton vehicle must have tyres 6 inches wide. The Locomotives on Highways Act, however, merely specifies 4 inches for all vehicles weighing over 2 tons. Assuming that a loaded vehicle weighs 5 tons and that the length of the arcs of contact is 24 inches and the tyres 4 inches wide, the pressure is 7·6 tons per square foot. Needless to say, macadam would never stand this. On the other hand, wide tyres are inadmissible owing to the impossibility of keeping the weight within the Act. We thus see that country roads are too soft for heavy traffic, and that heavy traction on them is, in their present state, not possible. We also see that with these roads and owing to the necessity of keeping down the tare weight, we are forced to make 4 inches width the maximum. We are really limited to a gross weight of 4·5 tons.

Before heavy traction can be indulged in and the country districts reap the advantages of cheap transport, the roads must be paved throughout as are the Liverpool streets, or at least made as good as the French roads. Owing, however, to this matter being in the hands of numerous local authorities uniformity in practice would be difficult. The Locomotives on Highways Act makes no provision for this, and hence it is faulty.

In my design I have adopted 5-inch tyres as being a bit better than the Act and less harmful to the roads, but here we are limited by considerations of weight, and this shows that the Act requires amendment.

Weight of Wagon.—So far, then, we have got our vehicle; all parts designed for a load of 7 tons. It will be as well to see how the weight comes out. We have:—

Framing and deck, including all bracing, connections, &c.	1,300 lbs.
4 horn plates	165 „
2 axles (hollow)	120 „
4 axle boxes	160 „
4 wheels	800 „
4 spiral springs and fittings	280 „
Frame of bogie and connecti	300 „
	3,125 lbs.

Or 1·4 tons.

Many of these items have been purposely increased, and an ample margin of strength has been allowed in all cases. We may, therefore, take it that a heavy wagon without machinery, such as indicated, can be built weighing about 3,000 lbs. This, of course, is only possible by the adoption of special high grade metal and by making all parts of no heavier section than is required after providing a proper factor of safety. As before said, I have adopted 3 as a suitable factor. Very careful workmanship is also requisite, and, needless to say, the ordinary coachsmith would have to be replaced by the accurate fitter. Hence such vehicle will be necessarily expensive at first.

Machinery.—We now pass on to consider the design and weight of the machinery; but before doing so some attention may be well paid to the general subject of weight and power. In order that a fair comparison can be made between automobile vehicles and other descriptions of automotors we must know the weight of machinery per I.H.P. I have, therefore, got out the following table which refers to different classes of automobile machines:—

Description of Automobile.	Weight of machinery per I.H.P.
Cargo steamers	400–450 lbs.
Mail „	400–420 „
Battleships and cruisers	260–300 „
Torpedo-catchers	45–50 „
Express tank locomotives	270 „
Admiralty launches (old type)	175-200 „
Steam lifeboat "Queen" (maximum power)	72 „
„ „ „ (normal „)	143 „
Typical road traction engine	1,100 „
Scotte, No. 1 (45 I.H.P.)	40 „
De Dion, No. 14 (45·1 I.H.P.)	44 „

These figures, which I believe to be reliable and representative of good average values, are worth a little consideration. It will be seen that the ordinary steam road traction-engine is the heaviest motor in use, being nearly three times heavier than the marine cargo-steamer motor, and no less than 20 times heavier than a torpedo-boat motor.

It will be noticed, too, that the Scotte and De Dion vehicles have machinery weighing about the same—or a little less—as that of torpedo-boats. In the latter, however, the weight includes condensers and their pumps, fans, and all the numerous valves, &c., whereas in heavy road motors the most simple designs will be used, and hence, judging from the prolonged and uniform success with which the Scotte and De Dion motors have run in constant work, we may safely allow in designing a weight of 45 to 50 lbs. per I.H.P. as being ample to secure good and substantial machinery. This weight implies the use of common materials of construction. If we employ nickel steel we can with confidence reduce this weight by certainly not less than 15 per cent., while a reduction by 20 per cent. would still give a superiority to mild steel. This means that we can safely specify for a high-pressure boiler and fast-speed motor and its accompanying gearing; the whole weighing not more than 35 lbs. per I.H.P. This means that on a margin of 1 ton weight for machinery we develop 64 I.H.P., or about 48–50 B.H.P. This would suffice to take a vehicle, weighing in all 14 tons, up a 10 per cent. grade at a speed of three miles per hour, against a resistance of 150 lbs. per ton.

Before leaving the question of the weight of machinery, I would digress for a moment in order to draw your attention to some facts connected with that automobile vehicle, the steam lifeboat "Queen," which is stationed at Liverpool. As you will notice, she has a very large H.P. and a comparatively low speed. In vessels of this class the Admiralty constant, $\frac{V^3 D^{\frac{2}{3}}}{\text{I.H.P.}}$, usually has a value of about 100. In the "Queen" it is only 32, showing a remarkably low propulsive efficiency.

Returning to our vehicle. As will be seen, we have but an available weight of 1·6 tons, and on this we have to provide all the machinery, and the question is, what type of engine and boiler shall we select?

We must, first of all, settle the maximum power to be developed and the heating surface. The power we have before determined is 33 I.H.P. As regards heating surface, the number of square feet per I.H.P. varies in the most erratic manner, according to the type of boiler used. Thus, in marine practice, we may say that the number of square feet of heating surface per I.H.P is given by $\frac{16}{\sqrt[3]{P}}$ where P is the boiler pressure. According to the rule we should have to provide no less than 91 square feet of heating surface. Now a return-tube marine boiler working at 100 lbs., and containing this amount of heating surface, will weigh no less than 2·25 tons. That is, the weight is 150 lbs. per I.H.P. of engine and 45·5 lbs. per square foot of heating surface. The particulars of this boiler are taken from the catalogue of a very well known firm of engineers. The weights are rather high, and in marine practice the weight for larger boilers is about 41 lbs. per square foot of heating surface.*

Water-tube boilers are, on the other hand, all that can be desired as regards lightness. Thus the "Lifu" water-tube boiler weighs but 25 lbs. per I.H.P. of engine; that is, a boiler that would supply all the steam required for our purpose would only weigh about 825 lbs. or ·37 ton.

Although water-tube boilers are so much lighter they are less efficient as regards heating surface than marine boilers, the latter of the Scotch type being among the most economical steam producers known.

The relation between heating surface and H.P. in the "Lifu" boiler seems to be expressed by—

$$\text{H.S. per I.H.P.} = \frac{25}{\sqrt[3]{P}}.$$

Thus we should require for our automotor about 130 square feet of heating surface as against 91 in a boiler of the marine type.

A few words about the Thornycroft boiler may not be out of place. This well-known and very successful type of boiler has been applied with advantage to automobile vehicles with some necessary modifications in the typical design. From published statements, however, it would seem that the relation between heating surface and H.P. is expressed by—

$$\text{H.S. per I.H.P.} = \frac{19}{\sqrt[3]{P}}.$$

* *See* Milton on Water-tube Boilers, "Transactions of the Institute of Naval Architects, 1894."

Whether this formula would apply to such small boilers as are required for our purpose I am unable to say, but I do not think it is materially incorrect. The weight per square foot of heating surface of this boiler is 12·1 lbs., which is vastly different from that of the Scotch boiler, but still not so good as the "Lifu," while the weight per I.H.P. is about 40 lbs.

From the data I have laid before you, which is that obtained as the results of many trials and tests, we can estimate with considerable accuracy the leading particulars of a boiler intended for automobile purposes on land. Taking 35 as the maximum I.H.P. we are to develop, and following the relation which obtains in the Thornycroft boiler as being a convenient mean between the heavy Scotch type on the one hand and the lightest water-tube boiler on the other, we find that we shall require, using steam at 200 lbs., about 115 square feet of heating surface, and hence the boiler will weigh 1,380 lbs., or ·62 ton. This is an extravagant estimate, and provides a power which would never be required in ordinary work, but only when climbing a 10 per cent. grade fully loaded. As there are no 10 per cent. grades even in this hilly district we thus have a large reserve of power. We might estimate on a different plan: On the level we know that the power wanted is, say, 28 for a speed of five miles, and against a resistance of 150 lbs. per ton. In actual practice the resistance in a well paved city would never exceed 60 lbs. per ton, while a speed of only four miles per hour is desired, the corresponding I.H.P. being but about 9. Thus an engine that will give off 25 I.H.P. would for all ordinary and practical purposes be ample, and applying the foregoing formulæ we find we could supply all the steam from a Thornycroft boiler containing 83 square feet of heating surface, and weighing but 1,000 lbs, or about ·45 ton.

As this boiler question is so important I perhaps labour it, but my object is to bring, in my own humble fashion, the experience and data of those who have had to make the construction of light and efficient boilers a special business to the notice of those who, having been untrammeled as to weight, have been in the habit of producing boilers that would deeply shock a naval constructor or torpedo-boat builder. I take up a catalogue, or six catalogues, of boilers and engines by different makers, and I find that a portable engine, giving off 30 effective B.H.P., weighs not less than 420 lbs. per B.H.P. or, say, 340 lbs. per I.H.P.—a wholly superfluous and unnecessary amount of weight. Hence it is not surprising that when these makers, wedded as they are to the traditions of the elders, and lavishly reckless in the use of metal, are asked to compete in building an automobile vehicle, giving off some 25 to 30 I.H.P. and to weigh under 3 tons, they decline, because this new practice is utterly opposed to all their well-worn canons of engineering. It is not so much to the builders of traction-engines that we must look for the practical solution of the problem set us by the Self-Propelled Traffic Association but to the torpedo-boat builders, such as Messrs. Yarrow and Thornycroft. Both these gentlemen, I need hardly remind you, are not only very distinguished engineers, but leading automobilists, Mr. Yarrow being an early pioneer in the movement.

Many automobilists seem to favour the vertical boiler, and hence a few words may be devoted to that. If we take the most economical type of vertical boiler, viz., the "Essex," made by Messrs. Davy, Paxman, and Co., we see that the relation between heating surface and H.P. is expressed by—

$$\text{H.S. per I.H.P.} = \frac{22}{\sqrt[3]{P}}.$$

The boiler having this amount of heating surface would weigh about 2·5 tons.

Of other types of boilers I should like to mention the Scotte and De Dion et Bouton. It is, however, so very difficult to obtain exact data. French manufacturers display an amount of reticence in these matters which must be, I should think, prejudicial in some respects. In these days all who have anything to sell have to imitate a distinguished statesman who lately visited you, that is, they must be their own "bagmen," and sing loudly praises of their own wares.

It may be of service to put in tabular form the relation between heating surface and weight of various types of boilers:—

	Weight per square foot of heating surface.
"Lifu"	6 lbs.
Thornycroft	12 „
De Dion et Bouton	23 „
"Essex"	47 „
Serpollet	53 „

Engines.—There are so many types of high-pressure fast-speed engines made now that we have quite a large field to select from. Objection has been taken to fast speed; but why? No one objects to fast-running engines for locomotives, or for electric-light plant, or for torpedo-boats, or for driving fans used for ventilating purposes. Why, then, should we object to such motors for automobile vehicles. The experience gained during the last 15 years, when high-speed engines have been so extensively used, is to the effect that, if well designed and well built, they will run for months together with the minimum of attention. We may take it that there is no valid objection to the employment of such motors for automobile purposes. MM. De Dion et Bouton, who possibly have a larger experience with road automotor-vehicles than anyone else, use motors running at 600 revs., and I was assured that no trouble was experienced during the many years that they have used such motors.

High-speed vertical compound engines developing up to 40 I.H.P. can be built on about 12–15 lbs. per I.H.P. That is using ordinary materials of construction. If, however, aluminium, bronze, or delta is used in place of cast iron and a good design adopted, the weight may well be got down to 10 lbs. per I.H.P. If, however, nickel steel and aluminium be adopted exclusively, we can get the weight down to 7–8 lbs. per I.H.P., or even less. From the foregoing we are quite justified in estimating at 45 lbs. per I.H.P. for the weight of boiler and engine; this comes to 1,485 lbs., say 1,500 lbs.

Gearing.—We now have to transmit this power. I suggest a two-speed gear involving the use of an intermediate shaft. I need not go into details about this as there is nothing special to remark except that the shafting would be hollow, the spur wheels of aluminium bronze; the motion would be transmitted to the rear axle by a steel stud-link chain. The weight of this gear together with the differential movement brake gear, levers, &c., would not, even at an extravagant estimate, exceed 1,200 lbs., this making the total weight of machinery to be 2,700 lbs. or 1·2 tons, which added to the 1·4 tons, the weight of the wagon, gives a total weight of 2·6 tons. The margin of ·4 ton or 896 lbs. would be expended on feed and bunker tanks, &c. As regards the quantity of feed-water to be carried, this, of course, should be as large as possible; that goes without saying, but a quantity that will suffice for at least three hours normal running should, I think, be the minimum. I may mention that traction-engines only carry a feed-tank capacity of 1½ hours.

Adhesion.—Before concluding, there is a matter which is of considerable importance to automobilists, and that is the adhesion of their vehicles on the roads. If the adhesion is insufficient, the vehicle will not start on admitting steam to the engine; or if climbing a gradient, and the adhesion is insufficient, the vehicle will stop or move backwards, notwithstanding that the engine is in ahead motion. In the discussion on the excellent paper by Mr. Worby Beaumont, read here at the beginning of the session, Mr. A. Holt alluded to this matter, and expressed the opinion that a want of adhesion would be experienced by heavy automotor vehicles under certain conditions. This opinion is corroborated by the experience of Sir D. Salomons, who, in his Society of Arts paper, mentions that on several occasions when hill-climbing the motor-carriage slipped bodily backwards, although the motor wheels were revolving for ahead motion. It is, therefore, important to consider under what circumstances slipping or insufficient adhesion will occur.

In moving any body along a plane surface, the least power required is some function of the weight or pressure upon between the body and the surface. Thus if a body rests upon a surface with a pressure of W lbs., then the pull, P, required just to move it will be—

$$P = \mu W.$$

That is, in order to produce motion the pull must be μ times the weight on the driving wheels. In other words, in order to maintain motion the adhesive power must exceed the tractive force. The value of μ varies, of course, with the nature of the surfaces in contact. In locomotives it is about $\frac{1}{7}$ to $\frac{1}{4}$. In road vehicles its value is about $\frac{1}{2}$ for iron wheels on macadam, but I can quite conceive that during rainy weather, when the streets are copiously lubricated with the familiar greasy mud, the value of μ would drop to $\frac{1}{4}$ or even $\frac{1}{5}$ on a hard granite road. Therefore, whether the adhesion is sufficient will depend upon the value of μ and the tractive force.

In order to find the tractive effort of an automobile vehicle in which, as is usually the case, the power is transmitted through gearing, we must first determine the velocity ratio between the motor and the driving-wheels; let this be n, say, that is, the motor-shaft makes n revs. for every rev. of the driving-wheels. Now, during one rev. of the motor, the vehicle advances $\frac{1}{n}\pi D$ inches; D is the diameter of the driving-wheel in inches. If P is the pull exerted in lbs., the work done during one rev. of the motor will be $\frac{1}{n}\pi$ DP inch-pounds. This must be equated to the work done in the motor cylinders in which the steam exercises a mean pressure of *pm* pounds per square inch, and since each cylinder is filled with steam twice during one rev., the work done by the steam will be $4 \cdot \frac{1}{4} \pi d^2 lpm$ inch-pounds, when d is the diameter of each cylinder, l the stroke, and *pm* the mean pressure. Hence we have

$$\frac{1}{n} \pi \, \mathrm{DP} = \pi d^2 lpm,$$

that is,

$$\mathrm{P} = \frac{nd^2 lpm}{\mathrm{D}}.$$

Suppose in a certain motor vehicle $n = 9$, $d = 5$ inches, $l = 6$ inches, and $pm = 80$ lbs., and D = 36 inches, then P = 3,000 lbs.

For compound engines we should replace d by d^1, and *pm* would be the sum of the mean pressures on the two cylinders divided by the ratio of the latter, and for D we should write 2D. The expression would then be—

$$\mathrm{P} = \frac{nd^2 lpm}{2\mathrm{D}}.$$

From the foregoing it follows that if μ be the coefficient of adhesion, then the least weight on the driving-wheels in order to prevent slipping must be—

$$\mathrm{P} = \frac{nd^2 lpm}{\frac{\mathrm{D}}{\mu}}.$$

Thus, taking $\mu = \frac{1}{2}$, the weight on the drivers in the example mentioned would be—

$$\frac{2 \times 9 \times 25 \times 6 \times 80}{36} = 6{,}000 \text{ lbs.}$$

So long as the vehicle was loaded, or partially so, the adhesion would be ample. If light, slipping would occur under favourable conditions, as the weight on the drivers would only be about one-half this.

Skilled Attention.—It has been objected that the use of steam boilers in automotor vehicles of other than the flashing type would necessitate the employment of skilled attendants, and this constitutes a reason for abandoning the use of all such vehicles. Now is this a logical or common-sense view to adopt? When this meeting concludes some of you will travel to your homes in your own luxurious carriages; others will proceed thither in the swift and dashing hansom, while others will go by train to their destination. Some of you cross the river, and others will patronise the democratic street car or omnibus. In all these vehicles a so-called skilled attendant is required. If you do not think a cabman or a bus driver is a skilled man, I would recommend any of you to make the assertion in the presence of one of these jehus, and I think his arguments to the effect that he *was* a skilled attendant would, at any rate, be satisfactory to him. If it be advanced that such an automotor vehicle as I suggest would require a skilled engineer then I venture to ask why?

In Egypt, in India, in Java, on the West Coast of Africa, up the Congo or Irrawaddy, you will see steam launches using high-pressure steam in charge of an attendant who, whatever else he may be, is anything but a skilled mechanic. Of course, in England we would be aghast at such things; we would raise the cry, the "safety of the public," the "lives of the workers," and such like claptrap. As a matter of fact, the skill that is exercised in driving an engine, whether this be an express locomotive or a steam crane, is of a very elementary kind. What is demanded of the men who drive engines is not skill so much as sound common sense. As fast as a new machine is perfected there is never any lack of so-called skilled attendants. I recollect that it was urged against the adoption of the Whitehead torpedo and the Maxim gun that they would require skilled attendants. If ordinary intelligence and common sense be skill, then the criticism is just. Skill is required in making a joint in a submarine telegraph cable, in compensating a chronometer, in adjusting a ship's compass, in making a pudding or ironing a shirt; but in driving a machine, whether a locomotive or the domestic mangle, little more than ordinary intelligence and common sense is wanted. I do not think that the reason against the employment of water-tube or ordinary boilers for automobile vehicles is that they require the service of skilled attendants holds good for one moment.

I now bring this long and I fear discursive paper to a close. My object in reading it has been to show, although imperfectly, that, notwithstanding the stringent and not altogether wise provisions of the Act, it is possible to comply with the wishes of those in whose interests the Act was *not* passed, and also to keep within, or rather to drive an automobile vehicle through, the Act itself.

A SERPOLLET TRAMCAR.

A TRIAL of a Serpollet tramcar, capable of carrying 50 passengers, was recently made in Manchester, speaking of which the *Practical Engineer* says:—"For one thing, the Serpollet car that was used, although far away an improvement upon, and in fact scarcely to be compared with, the hideous steam-cars at present in use on some tram lines in the immediate neighbourhood, was too much of a contrast with the light and elegant horse-cars that run over the Manchester lines, and would probably have to undergo considerable modification before it would be found acceptable in this district. The Serpollet car was of precisely the same type as those used in Paris, and of sufficient power not only to carry its own load of 50 passengers, but to draw also the trailing car, when required, with a smaller number of passengers. A self-propelled car of this type suitable to Manchester would undoubtedly have to be constructed on still more compact lines, and with the lessened driving power required this would no doubt be very readily accomplished, whilst other details as to more ornamental appearance and the arrangement of the gearing would also require special attention. The cost of running this self-propelled car with coke at 18*s*. per ton is estimated at 3·65 pence, or with oil at 3*d*. a gallon at 3·51 pence, per mile. The experimental test of the Serpollet car on the Manchester tram lines was successful in so far that it demonstrated its thorough efficiency for the work required, but in some other respects it can scarcely be said that it favourably impressed either the representatives of the corporation or the tramway company, who were present at the trial.

AUTOMOBILISM IN DUNDEE.

THE Dundee Tramway Company are seriously considering the expediency of adopting motor vehicles, with the object of developing the hiring department of their business, and, as a matter of fact, an order has been provisionally given to a firm of makers for one of these machines. Recently a deputation from the Company visited various centres in England and Scotland with the object of obtaining all information necessary on the subject of automobilism. As a result of this investigation they concluded that the motor and boiler made by the Liquid Fuel Engineering Company of Cowes, Isle of Wight, was the best one in the market. A van, lorry, or undercarriage suitable for any style of movable body, such as a 'bus, wagonnette, or covered van fitted with this motor, weighing under two tons, and constructed to carry a load of 30 cwts., could, it was stated, be supplied for £425. The deputation subsequently visited Birmingham, Nottingham, Sheffield, Bradford, Leeds, Newcastle, Glasgow, Hamilton, and Edinburgh. In Newcastle they saw the steam van and wagonette made by Toward and Co., St. Lawrence Ironworks, and at the Messrs. Stirling's works in Hamilton they inspected an oil-motor wagonette car seated for six people, the engine being a four-horse power one, and the weight, excluding passengers, under 19 cwts. A wagonette to seat six or eight people could, it was said, be supplied by the latter firm at a cost of £335. The deputation concurred that steam was the most suitable form of motive power for heavy traction, and that the improved Daimler motor, as applied by Messrs. Stirling, Hamilton, to the carriages built by them, was the best in the market for light traction. The deputation recommended:—That one vehicle of the wagonette type to seat eight persons, as manufactured by Messrs. Stirling, Hamilton, be ordered from that firm for light traffic; but that no vehicle for heavy traction be ordered at present pending further developments. In connection with this attitude of the Tramway Company towards automobilism the question naturally occurs, says the *Dundee Courier*, as to the manner in which they intend to apply it for traffic. In terms of the arrangement come to with the Town Council some months ago, the tramway system will fall into the hands of the city authorities in June, 1899. It is proposed, for example, to run a motor-car from West Park Road, the terminus of the car lines, to Invergowrie, and it is believed that a great deal of business would be the result of this scheme. It is also proposed that a motor-car should be run from Fairmuir to Downfield, and that another car should be placed on a run between Lochee and Birkhill. It is well known that, particularly in the summer months, there is a great deal of traffic between Lochee and Birkhill. The steep gradient in the neighbourhood of Camperdown policies is very trying to horse traction, and it is believed this is a route particularly suitable for a powerful motor vehicle, and that, having regard to the speed which can be attained by these vehicles, a very large number of persons would be carried to the country. It is also thought that it would pay the Company to acquire motor-cars for summer traffic between Dundee and Broughty Ferry on Saturdays.

ACCIDENTS WITH MOTOR-VEHICLES.

Petrol and Candles.—While repairing the oil-feed of a tricycle, at Chester, on February 10th, a young mechanic incautiously brought a lighted candle in close vicinity to the petrol tank, which must have been open. Result—outburst of flame, burning rather seriously, we regret to say, the young man, and damage to the machine.

Natural Antipathy.—A few days ago, in London Road, Thornton Heath, a horse attached to a cab took fright at a motor-vehicle, and galloped off towards Norbury. A coachman, who tried to stop it was knocked down, and a wheel of the cab passed over his thumb. His face was also badly grazed. The runaway was eventually stopped.

It Took Charge.—It appears from foreign advices that Prince Christian of Denmark, and his *fiancée*, Princess Alexandrine of Mecklenburg-Schwerin, had a narrow escape on the 2?th ult. They were taking an airing on a motor-vehicle between Grasse and Cannes, when the vehicle got out of control, ran down a hill, and landed the illustrious passengers in a deep gully. We are glad to say that they incurred no graver injuries than a few bruises.

Those Tram Lines Again.—Mdlle. Patrice, the actress, who is performing at the Lyric Hall, Oxford, met with a slight accident after the entertainment on Friday night, the 4th inst. She was proceeding to her lodgings in a motor-vehicle, accompanied by her husband and friends, when one of the front wheels of the vehicle caught in the groove of the tram line. The back wheels swung round, and one of the front wheels was wrenched off. The vehicle collapsed and the occupants were thrown into the road, but they all escaped with nothing worse than a severe shaking. The vehicle was, however, considerably damaged.

Insufficient Brake-Power.—On February 13th, while Mr. Lindfield, of Brighton, was driving a light oil motor-vehicle down a rather steep gradient at Purley Corner, on the Brighton Road, a bag fell out, and in putting on the brakes the steering gear gave way. The vehicle then began to run from one side of the road to the other, and eventually turned right round, running through a wire fence and striking an iron post, which caused the car to turn partly over and against a tree, catching Mr. Lindfield's leg between. He was thus pinned down and unable to move. At last two labourers came and released him. Unfortunately Mr. Lindfield succumbed to his injuries.

Motor-Car in Collision.—At Walton-on-the-Naze on the 28th ult., while a cart was returning from Walton to Clacton, it was met on the hill in the Kirby Road by a motor-vehicle belonging to Mr. J. H. Clamp of Colchester. The horse in the cart was frightened, and it tried to turn round; in doing so, the hind part of the cart was projected across the road. Those in charge of the motor-vehicle endeavoured to get past behind the cart, but from some cause they ran right into it, smashing off one of its wheels. The car was also much damaged, and the two men in charge of it were thrown out, but fortunately escaped with a shaking. The motor was taken on to Walton with damaged spring and axle, but was repaired next day.

THE LONDON GENERAL OMNIBUS COMPANY AND AUTOMOBILISM.

At the recent meeting of this Company, when a dividend of 10½ per cent. was declared, Mr. John Pound, the Chairman, gave the following particulars of the working of the Company:—The total receipts of the past half-year were £541,261, being an increase of £42,390; the expenses were £493,538, an increase of £50,589; and the profits on the working £47,723. To earn the £541,000 in the half-year they had run 1,151 omnibuses 13½ million miles, and carried over 86,000,000 of passengers; and although the receipts showed a satisfactory increase, yet the taking from each omnibus per day had been 4½*d*. less than in the corresponding period. With regard to the expenses, the cost worked out an increase of 11*d*. per omnibus per day. The excess on the road, yard, and general expenses was only ½*d*. per omnibus per day, which was more than accounted for by the increase in compensation. Half of the total increase had been incurred by heavier charges for provender and bedding, amounting to 5½*d*. per omnibus per day, and the balance was more than made up by the increase in shoeing of 1·4*d*. per omnibus per day. The maintenance was 2*d*. per omnibus per day, and stables and buildings 2·4*d*. Turning to the balance-sheet, he said the total trade profit stood at the commencement of the half-year at £889,000, and at the end of the year at £925,000, an increase of £36,000, of which they had expended £39,000 in new buildings, in addition to building 29 more 'buses and purchasing 425 more horses. A sufficient sum had been written off for depreciation, without encroaching upon their investments. From the profit and loss account they would see that the balance from last account was £13,265, the profit on the working of the half-year £47 923, and interest on dividends £5,000, so that they had £66,000 to deal with. Out of this they had placed £10,000 to reserve, bringing it up to £165,000; they declared a dividend for the half-year at the rate of 8 per cent., and a bonus of 25*s*., together equal to 10½ per cent. per annum, which would absorb £38,063, carrying forward £15 000.

In reply to a shareholder, the Chairman said that they were watching very closely the development of motor-vehicles, but as the prime cost of a motor-'bus would not be less than between £500 and £600, they did not see their way clear, at all events at present.

It transpired that this Company does not own the wheels of its 'buses, but hires them from another firm, the expense being £1,200 per month. The Chairman finds the policy a sound one, as it ensures the wheels being carefully looked after. Another useful item of information given was that the Company's horses are valued at £27 each, but cost between £30 and £50 apiece.

HOW TO EMPLOY ALL THE WHEELS OF AN AUTOMOBILE VEHICLE FOR PROPULSION.

As the application of motive power to road vehicles is so far confined mainly to those of light weight, considerable difficulty is experienced under certain conditions in obtaining the necessary adhesion. In nearly every motor-vehicle yet designed but two wheels only are employed in propulsion. On good macadam roads, with slight and easy gradients and a coefficient of about ·5, the adhesion is ample, but on paved roads, with steep gradients, and in muddy weather, the coefficient decreases and the adhesion becomes insufficient.* Could all the wheels be used for propulsion the adhesion, even under the worst conditions, would be ample. Unfortunately, it is difficult to design an arrangement which will be at once simple and efficient. The best arrangement we have yet seen is that devised by Messrs. Sydenham and Walkinson, of the "Crypto" Works, Clerkenwell. As will be seen, this design is extremely ingenious; not only can they use all the wheels for propulsion, but they can make the axes radiate to any point for steering. In order to accomplish these objects, the axle (which is driven in any convenient manner) is divided into four parts. The two middle parts are connected together at one end by differential gear (so that in turning the outer wheel revolves faster than the inner one), whilst their other ends are each connected to one of the outer parts of the axle by a universal joint.

* The theory of the subject will be found in the paper, "Some Points in the Design of Automobile Vehicles," in the present number.—ED.

Fig. 1 is a vertical longitudinal section partly in elevation of the axle and steering gear, and Fig. 2 is a plan. These figures show three of the four parts of the axle, namely, a, a^1, a^2, the fourth part, which is not shown, is to the right of the figures, and is similar to a.

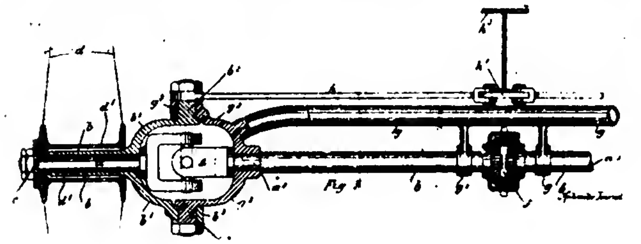

FIG. 1.

The parts, a, are free to turn in sleeves, b, and at their outer ends carry pins or cross-bars, c, engaging with slots on the hubs, d^1, of the wheels, d, so that the wheels turn with the axles. The inner

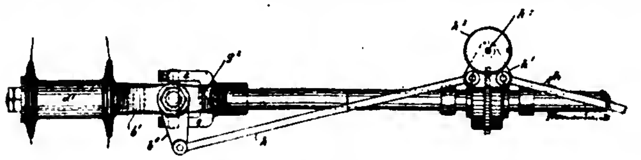

FIG. 2.

ends of the shafts, a, are connected by "Hooke's" joints, e, to the outer ends of the shafts, a^1, whose inner ends are connected by differential gear, f. The shafts, a^1, work in bearings, g^1, fixed to the

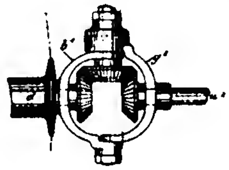

FIG. 3.

frame, g, of the machine. g^2 is a fork also fixed to the frame; at the top it carries a bearing, g^3, and at the bottom a stud, g^4.

The sleeves, b, have forks, b^1, at one end carrying studs, b^2, working in the bearings, g^3, and also bearings, b^3, to receive the

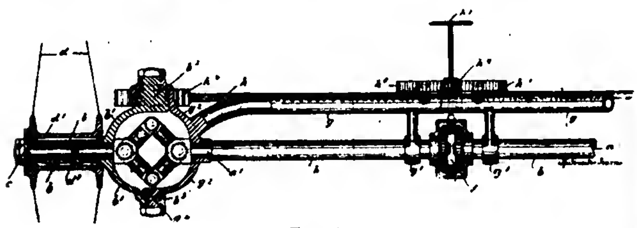

FIG. 4.

studs, g^4. b^5 are levers rigidly fixed to the studs, b^2, and connected by the rods, h, to the plate, h^1, which can be turned about a pivot, h^2, by the hand-wheel, h^3. This arrangement is not suitable when it is desired to turn the wheels through large angles, and in such cases

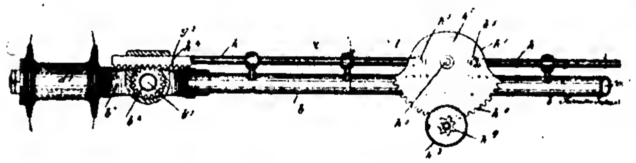

FIG. 5.

the Hooke's joint, e, is replaced by bevelled pinions as shown in Fig. 3, but the inventors prefer to adopt the arrangements shown at Figs. 4 and 5. Figs. 6 and 7 are a plan and side elevation of the carriage.

In this arrangement the Hooke's joint is replaced by a special form of universal joint, consisting of rods jointed together in the

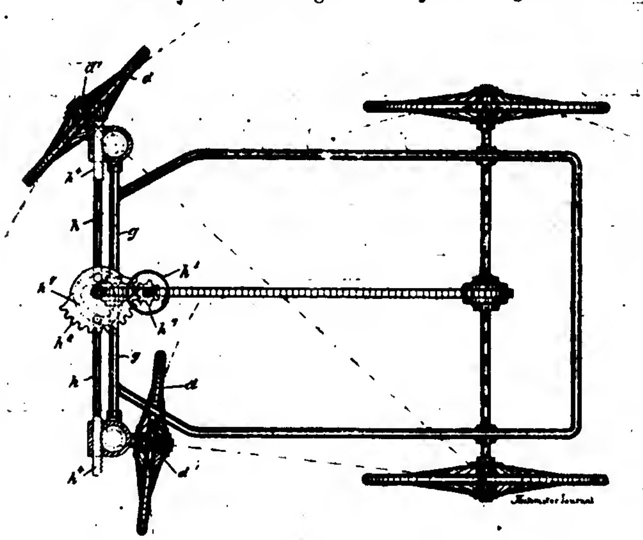

FIG. 6.

form of a parallelogram, each of the sides of which is made in two parts free to turn axially the one upon the other.

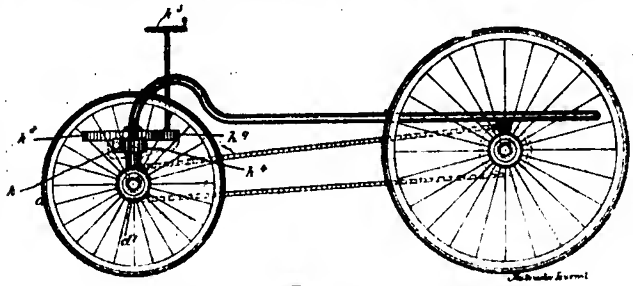

FIG. 7.

Fig. 8 shows an application of the latter arrangement to a tricycle. It will be gathered that much time and thought have been expended

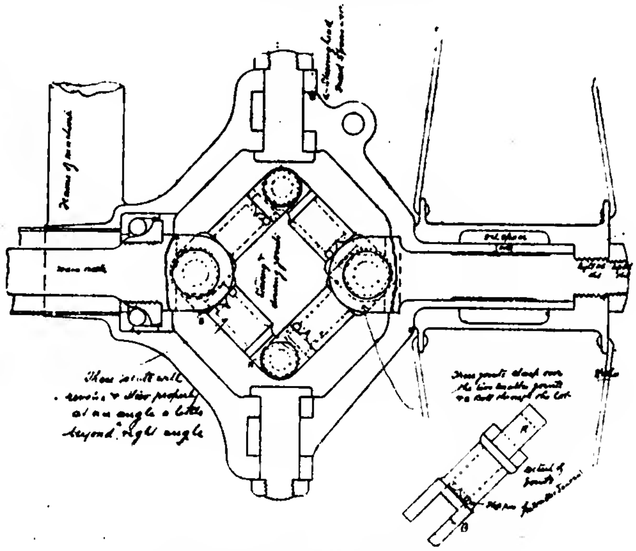

FIG. 8.

in working out these very ingenious details, and we have no doubt but that for light vehicles the proposed arrangement would be found advantageous.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to THE EDITOR OF "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. KING AND CO., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents:—*

London: POTTLE AND SONS, 14 and 15, Royal Exchange, E.C.
Wholesale: BRETT AND CO., 5, Pilgrim Street, Ludgate Hill, E.C.
Birmingham: J. MCCANN, 37, Union Street.
Manchester: JOHN HEYWOOD, Deansgate.
Newcastle-on-Tyne: C. C. ROSS, 35, Side.
Paris: HOMÈRE MOREAU, 97, Rue Nollet.
Victoria (Australia): PHILLIPS, ORMONDE, AND CO., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

MARCH 15TH, 1898.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month

[*For full programme and proceedings of the Self-Propelled Traffic Association, see p.* 205.]

1898.

March 19 to 26	National Sportsman's Exhibition, Exhibition Buildings, Earl's Court.
March 21 ..	Automobile Club of Great Britain, 4, Whitehall Court, S.W. Reading of a Paper on "Motor-Car Machinery," by Mr. Thomas Clarkson, A.M.I.C.E., at 8.30 p.m. The paper will be followed by a discussion.
March 26 ..	Ditto. Ladies' Night and Concert. Ladies will be admitted to the reception room and dining room. Evening Dress. A small orchestra, under the leadership of Mr. Louis d'Egville will play during the evening.
April 4 ..	Ditto. Third House Dinner, 7.30 p.m. Followed by a discussion.
April 7 ..	Ditto Start of Easter Tour; to end on Monday night, April 11.
April 24 ..	Paris Motocycle Critérium.
May 2, 9, 16, 23	Society of Arts Cantor Lectures—"Electric Traction," by Prof. Carus Wilson.
May 24 ..	Self-Propelled Traffic Association (Liverpool Centre) Heavy Vehicle Trials.
May 25 ..	"Concours de Fiacres," Paris. Organised by the Automobile Club of France.
June	International Italian Exhibition of Motor-Vehicles (Turin).
June 10 to 25..	Motor-Vehicle Exhibition, Paris. Automobile Club of France. Sections—(*a*) Automotor vehicles which have given proof of their practical efficiency; (*b*) Industries connected with automobilism; (*c*) Motors adapted for automotors; (*d*) Vehicles adapted for automotors.
June 15 to July 15	International Concours of Automobile Tricycles and Bicycles in connection with the Turin (Italy) Exhibition.
June 25 and 26	Brussels to Spa Race. Organised by the Automobile Club of Belgium.
July 3 to 11 ..	Race from Paris to Amsterdam, under the auspices of the Automobile Club of France.
1899	Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.
1900	Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

J. M.—Aluminium bronze can in most cases replace cast iron, but all bolt-holes require very careful tapping.

A. FORREST (Manchester).—Try the Crypto steering gear. See our present number.

T. LAWTON (Newcastle-on-Tyne).—The best work on the subject suitable for the student is Grover's "Modern Gas and Oil Engines." It can be obtained from the Technical Publishing Company, Manchester.

A. JENNINGS (London).—Consult Professor Boverton Redwood's work on "Petroleum" (Griffin and Co., London).

JOHN P. ELLIOTT (Newcastle).—No, we do not think soldered joints suitable for petroleum tanks.

T. HUNTER (Manchester).—Much of the feed water in your district contains a good deal of lime salts, and these would quickly deposit out. Use plenty of soda.

H. WILKINSON (Southsea).—(*a*) Messrs. Clarkson and Capel's address is 34, Queen Street, Cannon Street, E.C. (*b*) We shall be pleased to have particulars of your new water-tube boiler when completed.

A. W. PERKINS (Bournbrook).—The address of the Brayton Oil Motor Company (Limited), is 74, Coleman Street, E.C., and that of the Hoffmann Manufacturing Company (Limited), King's Head Court, Beech Street, Barbican, E.C., and of Delacroix Motor Syndicate, 4, Wynyatt Street, Clerkenwell, E.C.

W. HILL (Liverpool).—The 1898 POCKET-BOOK has been sent you. We note your remarks *re* Patent Specifications, and as far as possible shall try to deal with them in the best way for our readers.

PALMER PRYKE (King's Lynn).—(*a*) Journal and POCKET-BOOK both dispatched. (*b*) The Irish Motor Company was abortive. *See* our reports of the liquidation and return of shareholders' money, No. 12, pp 506, 514, 521. (*c*) We do not know the present address. The last we heard was in Paris.

T. W. HARGREAVES (Burnley).—The motor which you inquired about has really, as far as we can ascertain, done no practical work, and we should certainly not recommend it at the present moment, except for experimental purposes.

THE EVOLUTION OF THE MOTOR-VEHICLE.

IN many respects the present position of automobilism on common roads resembles the early days of that other automobile, the railway engine. Now, as then, we have the same differences of opinion on such matters as dimensions, proportions, fuels, &c. One engineer finds, under certain conditions, one motor more suitable than another, while another engineer tries the same motor under the same conditions and promptly abandons it as ntterly unsuitable. We say that the conditions under which radically opposite opinions are formed by competent persons are similar; this, however, rarely, if ever, obtains in practice. Apart from mechanical considerations, the "personal equation," which is such an important factor in physical science, is no less important in mechanics. It therefore does not do to dogmatise too much, nor to say that conclusions arrived at by one engineer are necessarily final. However divergent may be the views of engineers on any given mechanical problem, it must not be forgotten that such problems are, in every case, determined by physical laws which may or may not be known; but which, nevertheless, must, in the nature of things, exist.

We are led to make these remarks as our present issue affords an excellent instance of divergent views entertained by some of those engaged in the evolution of the motor vehicle. We publish in this issue our concluding portion of the report on "Les Poids Lourds," and a paper by Messrs. Simpson and Bodman, which was recently read by them before the Liverpool Centre of the S.P.T.A., and which evoked a prolonged discussion, a *précis* of which we also publish. Speaking broadly, the conclusions reached by the highly competent Commission appointed by the Automobile Club de France, under whose auspices the trials were made, is utterly at variance with those arrived at by Messrs. Simpson and Bodman. The Commission in question included some of the most distinguished French engineers, and their investigations and analyses, also their conclusions, may be accepted as final for, of course, those particular conditions under which the trials were conducted. As will be seen by referring to our report, these French trials are absolutely conclusive; they have demonstrated not only that motor vehicles carrying up to two and three tons can be constructed to work regularly, but also that services of such vehicles can be profitably worked.

These French vehicles have been so fully described by us in previous issues that we need not say more than that they one and all possessed features that Messrs. Simpson and Bodman absolutely condemn.

Thus they all had transmission gear—none worked direct. Now these vehicles, and many similar ones, are used extensively, and little or no trouble is experienced with their gear; but such gear is, according to Messrs. Simpson and Bodman, "a horrible *bête noir* in practice." Again, all those French vehicles use the differential, or "Jack in the box," motion; so do the very successful vans of the "Lifu" Company; so do the Daimler, Roots, and most other motors; and although we admit such gear is an evil, as leading to cost and complication, it yet, if properly designed and made, works well in practice. According to Messrs. Simpson and Bodman, they avoided it "at all costs," as being "liable to fire," &c. With the boilers, too, we see the same difference of opinion. MM. Scotte and De Dion have succeeded in making perfectly safe boilers—at least safe so far as the very rigid French regulations can ensure safety. Their boilers are simple, and no difficulty is experienced with the feed, yet Messrs. Simpson and Bodman have made five boilers which were failures, and are now at work on a sixth*; they also have fonnd great difficulty with the feed.

So much for the French vehicles. Making another comparison, the Lifu Company make an exceedingly light, safe, and economical type of water-tube boiler. Now, without infringing any one's patent, a very good water-tube boiler can be designed; yet Messrs. Simpson and Bodman could not succeed in perfecting theirs. The Lifu boiler is fired with heavy petroleum, and although the burner is, we think, noisy, yet in other respects it is efficient, and liquid fuel is most extensively and successfully applied by the Lifu Company, not only to yachts and small craft, but also, as we say, to their vehicles. Now what is Messrs. Simpson and Bodman's view? Judging from their own experience, they say:—"We made a number of experiments to burn liquid fuel. The sole value of liquid fuel in goods work would be its convenience, and it is almost impossible to overrate the value it would have in that respect. It saves from 150 to 200 lbs. in the weight of the boiler case. It enables the boiler case to be one-third shallower in depth. It enables one to force the boiler under stress of load in an exceptional degree. It is not bulky to carry. It is easy to obtain *en route*. But its disadvantages, we came early to the conclusion, absolutely damn it as a fuel to burn on vehicles at present. Its noise, when burnt in any quantity exceeding one gallon per hour, is absolutely intolerable. Its absolute unreliability nnder the slightest change, often quite imperceptible of circumstances in atmospheric condition. The unpleasantness of handling it; and, finally, its cost."

We might fortify the practice of the Lifu Company, and condemn the experience of Messrs. Simpson and Bodman, by a reference to the extensive use of liquid fuel in South Russia, on the Caspian Sea and on the Volga, to the favourable opinion, based upon practice, entertained for it by British and American naval engineers, and lastly, but not least, to the extending use of it on the Great Eastern Railway. Did space permit, we might show that in many other matters the views of Messrs. Simpson and Bodman are not supported by the experience or knowledge of others who are working on the problem of the evolution of the motor vehicle. Thus Mr. J. D. Roots, in our correspondence column, makes some very pertinent criticisms. This latter gentleman, we need hardly say, is a leading authority on oil motors and motor vehicles.

We have pointed out some of the divergencies in the experiences of Messrs. Simpson and Bodman and other workers, as in the very long and not altogether relevant discussion which ensued upon the reading of the paper, they were not mentioned; indeed, a pessimistic tone prevailed, and it would seem that the audience seemed to think it a very good thing that the authors of the paper *had* been so unfortunate and unsuccessful. We quite admit that a record of failure is useful, but we do not think the conclusion should go forth that a reasonably perfect motor vehicle to carry five tons cannot be produced because Messrs. Simpson and Bodman have failed. At any rate, before coming to any decision, we trust that readers of these gentlemen's paper will also study the report of Les Poids Lourds trials. To us these latter are conclusive that the motor vehicle has reached a practical shape in its process of evolution.

* We illustrate this boiler in our present issue.

⁂ As a result of negotiations which have been proceeding for some time, we understand that shortly there are likely to be some important developments which should very favourably affect the future of the motor-vehicle industry. When we are at liberty we shall publish full particulars, and we shall watch with interest the *volte-face* which those scoffers and pessimists will make who have so continually sneered at and held up to ridicule the visible results which have so far been attained in this movement, and which before many years are past are likely to effect the greatest industrial revolution of the age.

THE FORTHCOMING LIVERPOOL TRIALS.

As will be seen elsewhere in our present issue, we are enabled to furnish a good many particulars relating to the trials of the heavy traffic motor-vehicles which are to take place next May in Liverpool; under the auspices of the Self-Propelled Traffic Association. The arrangements are nearly completed, and, providing a sufficient number of vehicles are entered, the trials will be not only very interesting in themselves, but they will afford much valuable data, and will, further, enable definite conclusions to be reached on varions points upon which at present there is considerable difference of opinion. The judges have been selected with great care, and they may be relied upon, from their known position and character, to judge impartially. Sir David Salomons is too well known in the scientific world to need any reference from us; Professor Boverton Redwood is the great authority on petroleum; while Professor Hele-Shaw is the Professor of Engineering at Victoria University, Liverpool. Mr. Brodie is the Liverpool City Engineer; Mr. Calthorp has been largely connected with light railway construction in India, &c., and is now in consultation with the Colonial Office on the question of light railways for the West Indies;

Mr. Cottrell is the Engineer for the Liverpool Overhead Railway; and Mr. West is a well-known consulting naval architect and marine engineer.

The subscription fund was opened on March 1st, and already a large proportion of the required amount has been collected. Mr. E. Shrapnell Smith is the honorary organising secretary, and he may be depended upon to do everything not only for the comfort of the foreign guests from the Automobile Club de France, of whom we hope to see a good many, but also for the many engineers, capitalists, and others who will attend these trials with more than ordinary interest. We have not yet seen the arrangements for testing the vehicles, but we hope these will include brake, horse-power, and dynamometer tests. We also think that sketch maps might be prepared, showing routes, gradients, distances, &c. These trials will, as we say, be interesting enough, but those competitors who obtain the approbation of the judges will find their efforts repaid by abundance of orders.

THE POWERS OF LOCAL AUTHORITIES.

With the extension of local self-government there has been a desire manifested by not a few local authorities to obtain power enabling them to make bye-laws at their own pleasure, such bye-laws often conflicting with the law of the land. The granting of local self-government is no doubt a good thing in itself, but like so many good things it is open to serious abuse, and unless great care is exercised in Parliament we shall in a few years be confronted with the anomaly of each parish being practically a law unto itself. At this time of the year Parliament is asked to sanction very many Acts for the improvement of various districts, towns, &c. These measures being, as a rule, of purely local interest and non-political are relegated to a Committee of the House. After examination and the hearing of various "parties to the Bill" under discussion, the Committee report and, as a rule, the Bill becomes law. There is usually so much of this kind of legislation going on that it does happen occasionally that powers are granted to the local authority which enable it to make bye-laws, as we say, conflicting with the ordinary law of the land. This what we may term parochial law-making is in the majority of cases little more than a legal means of gratifying the predominant local prejudices. Hence, too great care cannot be shown in granting such powers. A case which illustrates the desire on the part of a local authority to legislate for everything and everybody within its jurisdiction is the Paignton Improvement Bill. Paignton is a watering-place in Devonshire, and its local authority is naturally enough desirous of improving the amenities of the district. To this end it is promoting a Bill in Parliament in order to obtain the necessary legal sanction to make improvements. To this no one will object. but it is to matters affecting personal rights that objection will be taken to the Bill. For example, the Council seeks power to make bye-laws regulating such matters as the length of bathing drawers and costumes. Surely such things may be left to the natural good sense of the community. In short, the Council, typical, no doubt, of the local authority everywhere, seeks powers to make bye-laws affecting nearly everything. Does a little boy wish to make a sand castle on the beach there is a bye-law regulating "the user of the seashore." We should not like to live at Paignton.

What, however, more concerns our readers is not the regulations that the Council of Paignton—no doubt very worthy and respectable persons—may make as regards bathing, but their attitude as regards motor vehicles. In the Preamble the word cycle in the Bill "includes bicycle tricycle motor-car or other similar carriage whether propelled by mechanical means or otherwise"—the "or otherwise" is good. Turning to Clause 83 (by the way, what a large Act is required for such little towns as Paignton), we find that "the Council may from time to time for the prevention of danger (of course) from the use of cycles and traction engines make and enforce bye-laws preventing the rate of speed beyond which cycles and traction engines may not be ridden upon any highway or on any street or public place within the district and for *otherwise regulating* the use of cycles and traction engines upon any such highway street or public place as aforesaid."

For a small place this is not bad. As will be seen, the Council seeks to discriminate against the motor vehicle by limiting the speed, and by *otherwise regulating*, it can effectually and practically prevent automobilism within its borders as well as did those local authorities of Cheltenham hinder Gurney some sixty years ago. The presumption of some of these petty local bodies is astounding. Parliament sanctions automobilism, and a petty body of residents of some obscure village at once seek powers to regulate in *their* manner what has already been sufficiently regulated. Here now is a good opportunity for the Self-Propelled Traffic Association, the Automobile Club, and the Cyclists' Touring Club, to render a service to the large and growing public that believes in horseless vehicles. These bodies should exert every effort against this Bill, which has already passed its second reading, and get, at any rate, this obnoxious clause expunged. While on the subject we would suggest, both to cyclists and automobilists, the expediency of forming a Joint Committee, which should examine all Bills promoted by local authority, and if necessary appear in opposition to them.

DISFIGURING THE THAMES EMBANKMENT.

All vehicles, of whatever description, have their natural environment, in which they appear harmonious adjuncts to the scenery. A carriage and pair is—or, rather, was—the complement of a scene in Mayfair, now it is the handsomely-appointed motor-carriage. Both would look extremely out of place in, say, the Mile End Road; similarly a coster's barrow is just the thing which imparts the touch of realism to a scene in the New Cut, but in Park Lane it would be a most horrible blot upon the surrounding features. There are certain districts and streets in which certain types of vehicles are suitable, but the Thames Embankment is *not*, we submit, the place for horse tramcars. To disfigure the most magnificent boulevard in Great Britain, if not in Europe, by the hideous, obsolete, horse-drawn street car is an absolute outrage upon the community. One does not need to be an artist or an art critic to see the truth of this. Every one, with any sense of the beauty attaching to noble structures situated amid scenes of considerable natural beauty, will, we are sure, agree with us in our contention. Why should we make one of our very few handsome thoroughfares as depressingly ugly as, say, the Walworth Road or the Commercial Road? Rather let us beautify where we can; our streets need it badly enough. The reason for this attempted desecration of the Embankment is merely, to employ the familiar platform jargon, "to give facilities to the teeming population of South London to reach their employment in town." This is, we quite admit, a laudable enough intention on the part of the County Council, but is nevertheless no justification for the æsthetic outrage complained of. The only vehicles, in our opinion, which should be permitted to use the Embankment, or which can use it without jarring upon one's sense of the fitness of things, are high-class motor-carriages (not vans), pair-horse carriages, private cabs, and cycles; all other vehicles constitute an eyesore and are an offence. The London County Council is promoting a Bill in Parliament to enable them to run tramcars over Westminster Bridge and along the Embankment. This has aroused a vigorous opposition, and the Bill will be contested point by point. The Automobile Club is, we are glad to say, using its not inconsiderable influence in opposition to the scheme, and has contributed to the funds necessary. Of course we, and all who oppose the measure in any way, will be told that we are pandering to the luxuries of the classes rather than improving the means of travelling for the masses. This is not so, because the object to be attained can be effected by other means. The new underground railway will provide a cheap and efficient passenger transit, while the Thames offers a much better thoroughfare. Let the London County Council develop a proper service of water automotors, they will in this have the support of all classes, but to wantonly disfigure the beautiful Embankment is to give needless offence and to still further enhance that feeling of hostility with which the Council is regarded in so many quarters.

A CHARACTERISTIC FACTOR IN THE POWER OF PETROL MOTORS.

The following is a free translation of a useful article by that well-known authority, M. E. Hospitalier, and which appeared in our contemporary *La Locomotion Automobile.* We reproduce it here, as the actual data relating to the petrol motors usually employed are scarce, while well authenticated trials are still more so. The following information will, we think, be much appreciated by many of our readers as it will enable them to judge the capabilities of motors submitted to them :—

In comparing impartially the movements of automotor-vehicles in racing every one at the present time agrees that speed alone is an insufficient factor. as it only really represents mere power. The first care is usually to determine in which formula of allegence* the motor power appears best, but the determination of this factor presents difficulties upon which it is useless to lay stress. We can only refer somewhere else to the value of the disclosures of builders or competitors, as it is the rule in a meeting to verify all the points in a statement, and this is precisely the fundamental objection made to races that only permit of one controlling factor—speed.

In studying the principal elements of the construction and working of a certain number of motors driven by petroleum, and in comparing certain specific factors, these should be the same theoretically for motors worked on the same cycle, we have noticed that one of these specific factors (we are going to explain it definitely presently) was invariable at nearly 20 per cent. for the eight motors compared, in spite of the difference in proportion, system, and power, &c. There is then a factor that continues, so to speak, steady for all motors worked by petrol, and it is this factor that we propose to utilise by deducing from it the power of the motor that ought to figure in the formula of allegence. This factor is the specific displacement of pistons, calculated, as we are about to show, from experiments made in motors, of which the following data are known :—

Number of cylinders ;
Diameter of pistons in millimètres ;
Stroke of pistons in millimètres ;
Normal angular speed in revolutions per minute ;
Available free power on shaft or brake in H.P.

Principal Elements of Construction and Working of some Petrol Motors.

9. H.P. of motor in poncelets † ...	0·95	2·0	2·8	4·12	3·4	3·7	4·9	5·3
10. Specific displacement of pistons in litres per second and per poncelet	9·36	12·8	11·7	7·7	8·9	9·4	9·2	10·3

* Cubic feet = litres × ·035.
† Poncelet = H.P. × ·763, or ·981 kilowatt.

With these data we can easily calculate the area of the piston and the volume of the cylinders, then, knowing the normal angular speed of the motor and the number of cylinders, it is equally easy to deduce the displacement of pistons expressed in litres per second ; a displacement being equal to double the volume of the cylinder (out and instroke), multiplied by the angular speed of the motor in revolutions per second, and by the number of cylinders.

Knowing the power of the motor in poncelets, and the displacement of pistons in litres per second, we deduce from it, by dividing the second by the first, the specific displacement of pistons, which is found expressed here in litres per second and per poncelet. Now the comparison of eight motors, of which the principal elements of construction and working are summed up in the above table, show us that this factor is sensibly steady, the dimensions explain themselves easily by the variations of the factors multiplied, which unite in the production of motor power. We can then admit, without obvious error, that practically "The quotient of the displacement of pistons of a motor worked by petrol, by its power is a constant quantity, or that the power of a petrol motor is practically proportionate to the displacement of pistons."

Now, if we compare the figures obtained and summed up in the table we see that the specific displacement varies between 8 and 10 litres per second and per poncelet. We do not commit a very big error in saying that the normal power of a motor driven by petrol (expressed in poncelets) is equal to the tenth of the displacement of pistons, expressed in litres per second. Then having a measure, a counter of revolutions, and a chronometer, these are sufficient to determine the real or probable power of a motor, a power of which the value can be thus figured out in the formula of allegence. If the angular speed of the motor leaves any doubt it is sufficient to calculate it after the race by, of course, taking note of the average speed and discounting stoppages.

If the characteristic factor that we propose is not utilised in races it can always be used for the general information of builders, and furnish them with a first approximation in a question where precise particulars are still very rare.

AUTOMOBILE CLUB BELGE.

The Secretary-General, M. le Comte de St. Pierre, asks us to state that the great Automobile Race organised this year by this club will take place between Brussels and Spa on June 25th and 26th. The proposition to have a race between Namur and Spa has been abandoned. We hope to publish further details in time for intending visitors.

A Note to the London Fire Brigade.—The Fire Commissioners of Hartford. Conn., are looking about for a motor hose-cart, so satisfactory. says the *Horseless Age*, is the record of the self-propelled fire-engine they have had in service for several years. While investigating this matter they have run across a novelty in fire-engines which interests them greatly. The engine is a storage battery affair and can be run out at short notice and go at high speed. It is lighter by the weight of a boiler than a steam fire-engine, for it does not depend upon its own power for pumping after it reaches the scene of duty. It is intended only for duty in the city territory, where there is electric service. and on arriving at a fire simply connects with an electric wire and runs its pump as a trolley-car runs its motors.

Messrs. Simpson and Bodman's Paper.—On February 22nd a very interesting paper was read before the Liverpool Centre of the Self-Propelled Traffic Association, by Messrs. D. H. Simpson and W. L. Bodman, narrating experiments which they have carried out. These gentlemen appear. says *The Engineer*, to have been peculiarly unfortunate in the matter of boilers. They have failed to find a satisfactory gauge glass, and vibration has shaken the tubes out of the tube plates. With oil-fuel they have had such difficulties that they unhesitatingly reject it. They have been curiously unlucky in their experiments. These, however, refer mainly to vans and vehicles much larger than any likely to be used as pleasure carriages, and so nothing that they have discovered in their practice has much bearing on what we have just written. It may perhaps be worth while to point out that the jarring trouble may be almost entirely got over by carrying the boiler on lugs, resting on thick indiarubber rings interposed between the lugs and the frame of the vehicle. These will completely avert the small vibrations which are so mischievous.

* "Characteristic formula" would convey a more definite meaning to English engineers.—Ed.

NOTES OF THE MONTH.

THE Dunlop Company think that the motor-vehicle is in comparison with the cycle much better and more efficient.

HIS Royal Highness the Duke of York is an automobilist, and has been taught the "nobler art" by the same driver that has taught Lord Iveagh and other noblemen.

THE Royal Engineer Committee of the War Office has appointed a sub-committee of its members to consider the adaptability of motor-vehicles for purposes of army transport.

THE Liverpool Overhead Railway, in view of increasing speeds and weight of cars, are laying down Muirhead's steel railway chairs. They are the first electrical railway to have done so.

THE Lighting Committee of Bournemouth have recommended that the surveyor be instructed to advertise for designs and tenders for motor-vehicles for the collection of house refuse. The official invitation for tenders appears in our advertisement columns.

ACCORDING to an amusing account of the "Lifu" mail van, which is rendering such an excellent account of itself, the driver is an American who came over specially to take part in the classic race of horseless miscellanies from London to Brighton on November 14th, 1896, and he won.

A NEW broadsheet, entitled "Advice to Boiler Attendants," has been issued by the Manchester Steam Users' Association, of 9, Mount Street, Albert Square, Manchester. The hints and warnings given have been judiciously drawn up, and if generally acted on would go far to entirely abolish boiler accidents.

THE two motor-cars which were put on between Sandbank and Dunoon have been largely patronised, and have attracted considerable attention. The cars are the property of the Glasgow and West of Scotland Motor-Car Company, and they intend to put on seven additional cars, beginning in June.

THE first motor-car for hire in the streets of Glasgow has been licensed by the magistrates of that city after having been formally tested by the Chief Constable. The car is owned by Stirling's Motor-Carriages Co. (Limited), and is now running on the streets of Glasgow, others are to be added as the demand increases.

AT a recent meeting of the Rhyl Town Council a letter was read from the Motor Touring Company, Llandudno, applying for sanction to station two or three of their motor-cars at Rhyl. The clerk was directed to enquire what rent the Company would offer for a station on the Market Ground, and what would be the fares for the public. If the replies are satisfactory the committee are disposed to favour the application.

IT is said that Mr. G. W. Clark, of Rochester, is constructing a steam triplet to be used for pacing purposes which is expected to attain a speed of a trifle less than a mile a minute. When fully equipped it will weigh about 400 lbs. The two men behind the steersman sit side by side over the rear wheel. A peculiar feature of the triplet is a contrivance by which two auxiliary wheels are lowered to hold the machine upright until speed is attained.

MR. COUNCILLOR CALCOTT, on behalf of the directors of the Midland Cycle and Motor Exhibition, recently held in Birmingham, has handed over a cheque for £50 to the Coventry and Warwickshire Hospital, being a portion of the sum allocated by the board for charitable purposes out of the profits of the enterprise.

THE provost, magistrates, and commissioners of Dunoon inspected the motor-vehicles of the Glasgow and West of Scotland Motor-Car Company (Limited) lately, and after a very successful run to Sandbank and back expressed themselves thoroughly satisfied with the machines, and granted licenses for these to ply for hire. The cars started in regular brake service on the 4th inst.

LECTURING recently at Wolverhampton, Professor Sylvanus Thompson, in the course of his remarks, said the use of horse-power on the world's tramways had greatly declined between 1890 and 1897, the mileage being reduced from 5,000 to 900, while the mileage of electric tramways had increased from 1,262 to 13,000. The province of Ontario had 900 miles of electric tramways—more than in the whole of Europe.

THE man who invented the phrase, "—— is still in its infancy," probably never had an idea to what iteration it would be subjected. Every public improvement is to some people still in its infancy. Thus to many people "the electric light is still in its infancy," and now a *Manchester Guardian* man, evidently a nautical automobilist, commences and ends—and, let us add, spoils—a most interesting article with this abominable phrase.

PRIZES for motor-cars are to be offered in connection with the Turin Exhibition announced for opening next summer. They include £160 for the vehicle judged as best constructed and most efficient in performing the journey from Turin through Asti to Alessandria and back, 200 kilometres; £120 for the vehicle, of Italian make, showing best construction; £80 for the one that does the journey in the quickest time; £40 for the simplest and cheapest; and £20 for the best motor-cycle.

THE Schoen Pressed Steel Company, of Pittsburg, has secured a contract for the manufacture of five steel coal cars, with a capacity of 50 tons each, for the Pennsylvania Railroad. These cars will be the largest ever built, and will be experimented with on the Pennsylvania Railroad in the coal regions. They will be flat-bottomed, 30 feet long, and 10 feet high from the rail, and they will be made of heavy plate steel. Five steel sample ore cars are also being built for the Butte, Anaconda, and Pacific Railway of Anaconda, Montana.

AT a meeting in the Inverness Town Hall on the 3rd inst. a proposal was submitted for the introduction of a motor-vehicle service in Inverness. Mr. William Burns, solicitor, presided. It was proposed the car should run from Drummond to the town, from Millburn to the town, and also from Kessock Ferry to the town. The Chairman stated that a 'bus to carry from 15 to 20 passengers could be obtained for £600. It was agreed to defer further consideration of the scheme until a future meeting.

THE whole of the men at Crewe and Carlisle employed at the extensive works of the London and North-Western Railway Company commenced to work full time from Monday last, the 28th ult. The total number employed is from 7,000 to 8,000 men. It is five years since full time was worked at these places. In several of the shops the men are required to work overtime, as business is so pressing. This is another indication of the great activity in the engineering trades of the country, an activity all the greater by reason of the long stoppage.

Commenting on the tramway problem in Newcastle-on-Tyne the *Newcastle Chronicle*, in its issue of the 3rd inst., says:—"The ideal public carriage is one which is self-contained, which can travel on any part of the road, which, therefore, does not need to have a monopoly of the centre of the street accorded to it, and which does not bring traffic to a standstill when it breaks down. Such a carriage is now within the sphere of practical engineering. The argument for the tram-line, which of itself is an unmitigated nuisance and a danger as well, has been that it affords smooth riding.

The number of applications for patents during the year 1897 was 30,936, as compared with 30,194 in 1896 and 25,065 in 1895. Although the number of patents applied for illustrates the progress of inventive activity, it does not, says *Knowledge*, afford any reliable criterion as to the number which arrive at maturity. Out of the 30,194 in 1896, for example, only 13,360 were completed, the rest being allowed to lapse after the nine months' protection. Not a few of the applicants for patents are women, of whom there were about 700 in 1896; some 150 of these inventions relating to dress.

The secretary of the Motor-Car Club has, as he writes to a contemporary, been refused an amateur license because on motor-car day he rode in an exhibition race on motor-cycles against a professional at Sheen House. This is a curious case, and judged from different standpoints presents different aspects. From one point of view, says the *Athletic News*, steering a motor is not cycling or any other athletic exercise, so riding against a professional cyclist does not disqualify a man any more than playing at billiards, cricket, or football with him. I know a professional jockey who has competed under A.A.A. rules. If, however, the committee regard "motoring" as cycling, they are perfectly right in upholding the amateur definition.

It is proposed to establish a service of motor-vehicles between Lowestoft and Yarmouth. These motor omnibuses, being capable of a speed of 12 miles an hour, will render practicable the journey by road between these two important towns in three-quarters of an hour; and inasmuch as motor-vehicles are incapable of fatigue each omnibus could accomplish, in a 12-hours day, four journeys a day each way. The type of motor employed will be Daimler petrol engines, of from 8 to 10 H.P., supplied by the Motor-Carriage Supply Company (Limited), of London. The motor omnibuses running direct from Lowestoft to Yarmouth and back would be serious competitors with the railway, for whilst the distance by road would be practically half that of the rail *viâ* St. Olaves, the motor-omnibus would run for almost the whole way in view of the sea, and would drop its passengers anywhere along the route, or take them actually to the beach at either end.

"Riding the road-skate to the common danger" constitutes the latest police-court charge. The road skate, however, is nothing in the nature of a skate. It is defined as "a pair of small bicycle wheels with wooden supports for the legs." It is, in fact, the nearest approach to the human form divine made bike that has yet been seen. When ridden by a well-dressed lad from Hammersmith to the City it is said to have "beaten the underground trains." If it can do no more than that, it would not appear to be anything very fiery and untamed. Nevertheless, it came so sharply into a City police-constable as nearly to knock that officer down—so, at least, he deposed. On the other hand, the well-dressed boy part of it declared that it was going at a walking pace, and that it was the policeman who knocked *it* down. There being evidence to bear out this latter statement, the magistrate dismissed the summons, and merely cautioned the road-skate not to get knocked down by policemen for the future.

According to a report made by the United Traction Company, of Pittsburgh, to the *Street Railway Journal*, the average life of its wheels is 35,000 miles, and it estimates that about one-third of this life is secured by prompt grinding of the wheels when flat spots are developed. The Consolidated Traction Company, of the same city, buys its wheels on a mileage basis, the manufacturers guaranteeing a life of 30,000 miles for each wheel, replacing those which have a shorter life, and obtaining credit for those which have a longer life. The general manager of the United Traction Company, of Pittsburg, is somewhat less precise, and reports the average life of motor gears on his line as two years, and the average life of pinions nine months. The latter service is an exceedingly severe one, on account of the many grades on the line. The average life of trolley wheels of this company is 1,000 miles, and the conditions under which they operate are quite severe, as the company has on its main line 18 railroad crossings. A tempered copper wheel is employed.

A gas traction plant of tramcars has been started between Lytham and Blackpool. The Blackpool, St. Anne's and Lytham Company was the first to adopt gas traction in this country. There is nothing in the external view of the car to give any idea of the motive power employed, and it is only by opening the doors let into the side that the motor can be found. The engine, which is continually running, even when the car is stopped, is controlled by the driver from the front platform. It is one of 15 H.P., and is placed under one of the side seats. The ignition is effected by the electric spark. A governor changes the speed from 80 to 260 revs. a minute, and the Board of Trade Regulations restricts the speed of the car to eight miles an hour, but the engine is capable of driving it much faster. There are two charging stations, one at the Blackpool end and the other at Ansdell end of the system, and the temporary tram-shed and station are at Stoney Hill, South Shore. The Parliamentary estimate of the cost of the line was £52,038, but this was reduced by £18,000 owing to the Blackpool Corporation constructing the line within the borough and leasing it to the Company.

THE AUTOMOBILE CLUB OF GREAT BRITAIN.

The Second House Dinner of this Club was held on the evening of the 7th inst., at the Club premises, 4, Whitehall Court, when the chairman for the occasion was Sir William Abdy, Bart. Amongst those present were the following:—Messrs. W. Worby Beaumont, E. H. G. Brewster, Frank Butler, R. M. Buttemer, Herbert C. Capel, J. Clarkson, Captain Cunningham, Messrs. S. E. Edge, T. W. Staple Firth, F. H. Fraser, K. Hodges, W. W. Hodges, A. Hening, Ernest M. C. Instone, C. Johnson, Shaw Kennedy, S. H. Lane, Colonel Lee, Messrs. W. J. Leveburo, W. J. Leonard, P. McManus, J. McManus, C. Harrington Moore, Arthur Mulliner, J. W. Parr, Forster Pedley, T. J. Perrett, Captain Sampson, Messrs. L. Sampson, Frederick R. Simms, G. H. Thrupp, Sir J. R. Somers Vine, C.M.G., and Mr. A. J. Walter.

Before leaving the dining-room the Chairman said:—"At a discussion that was held here on Saturday last a proposal was made and subsequently adopted by the Tour Sub-Committee as to the Easter tour. It is proposed to start from the Club at 3 o'clock on the Thursday before Easter, to sleep on the Thursday night at Guildford, and to delay the start on Good Friday until noon in order to give members who may not be able to start on the Thursday an opportunity of catching up the party by starting early on Friday morning. The tour will then proceed to Winchester, where Good Friday night will be spent. On the Saturday the party will go through Southampton to Chichester, where they will stop the night. On Easter Sunday it is proposed to run to Arundel, and after having seen the Duke of Norfolk's Castle and the beauties of Arundel Park, to go to Littlehampton for mid-day dinner. In the afternoon the party will proceed to Worthing, and members will have the option of remaining there for the afternoon or running to Brighton and back. The Sunday night will be spent at Worthing, and on the Monday those who are anxious to return at once to town may proceed to London direct, whilst others will go through Lewes over Crowborough Head to Tunbridge Wells, where Easter Monday night will be spent, and on Easter Tuesday the journey will be made through Sevenoaks to London, where members will re-unite at the Club on the Tuesday evening. This promises to be an extremely interesting and picturesque tour, seeing that it will pass through some of the prettiest country in Surrey, Hampshire, Sussex, and Kent.

"It is particularly hoped that those members who have not motor-carriages will accompany the tour on bicycles or by horse vehicles, and that those who are unable to follow the tour throughout will make a point of joining it even if it be only for one of the nightly club dinners at one of its stopping places, all of which are easily accessible by rail.

"I wish to draw the attention of members to the maps which the Committee have recently purchased and placed on the Club walls. These maps are so mounted that they may be removed from their frames for measuring purposes; they are on the scale of ¼ inch to a mile, and are coloured to show the various altitudes. These maps should prove invaluable to the travelling portion of the members.

"Concerning the proposed tramway for Westminster Bridge and along the Thames Embankment it is certainly one of the functions of this Club to oppose this measure, and the Committee have already subscribed five guineas towards a fund being raised to oppose the Bill.* It is hoped that members will also subscribe to this fund. But there is another way in which they may materially help the opposition of the Bill, viz., by using all the influence that is in their power to induce members of Parliament with whom they may be directly or indirectly associated to attend and vote against the second reading of the Bill, which is fixed for Thursday next, the 10th inst., at three o'clock.

"The last point on which I have to speak is to remind members that on Saturday the 26th of this month—that is to say, next Saturday fortnight, a concert is to be given at this Club to which ladies will be admitted. The programme is not at present fixed, but I am told that a very excellent little orchestra consisting of ladies and gentlemen, some of whom are undoubtedly amongst the best amateur musicians in London, will play some most charming dance music, and that two or three good vocalists have already promised to assist in the concert. There will, on this occasion, be no charge for admission of members' friends, and it is hoped that advantage will be taken of this opportunity to introduce many visitors to the Club with a view to making it widely known and to increasing its roll of members."

Subsequently an interesting discussion took place on "The Bearing of Past Inventions on Future Motor-Car Design," the opening discourse, illustrated by some 40 lantern slides, being given by Mr. Worby Beaumont.

Mr. THOMAS CLARKSON said that Mr. Beaumont had shown that the history of the past motor-car inventions was mainly the history of their boilers, as in other respects they differed but slightly. Important as the boiler design unquestionably is there is for the modern steam-car designer a more difficult problem in the heating arrangement for the steam generator, for, as Mr. Beaumont had pointed out, the public would not be satisfied with the arrangements that were put up with 60 years ago, and Mr. Clarkson could speak from wide experience that the burner question was, in the fullest sense, the "burning question" in steam-car design. It also appeared to him that one of the important points in successful motor-car design must be combination with the coachbuilder. A carriage builder at present was not able to give any satisfactory design, as if asked for a design he generally gave either a box on wheels or a platform on wheels. The reason of this is that he does not appreciate the essential functions of the different parts of the machinery which have so important an influence upon the location of the several parts upon the car. The question then arises: Should the coachbuilder make himself acquainted with what are the essentials in a motor, or should the motor designer make himself acquainted with what are the essentials of a carriage? Mr. Clarkson was of opinion that it was easier for the engineer to learn the essentials of carriage building than for a carriage builder to learn the essentials of a motor, and only in this way does it appear to be possible to secure that unity of conception which is so necessary for the production of a really satisfactory design of vehicle.

Sir SOMERS VINE, who has recently been elected a member of this Club, said that although he had but a small knowledge of the technical side of the motor-carriage question, he had been interested from the outset in the introduction of the principle to this country. He had a firm belief that automobilism had found a place in this country, and would prove to be one of its great industries; and during his recent travels throughout the length and breadth of the Australian continent, he had been convinced that there was a great opening for transport by means of motor traction in Australia and other Colonies. In the Colonies they had not the network of railways which existed in the home country; the trunk roads were fairly metalled and in good condition, and necessarily so, seeing the large amount of road transport which took place over them. He had only recently seen a procession of trolleys each bearing some 6 to 8 tons of wool, and each drawn by from 12 to 16 draught horses, taking the wool from the outlying sheep stations to the railway or to the coast, and he believed that there was a remunerative opening for the industry in Australia and elsewhere among the dependencies of the Empire.

Mr. E. T. HARRAP said:—It has been stated that the heavier motor-wagons would hardly find an application in this country, but having carefully considered this matter with the motor-car makers I am advising, I am certain there will be a very big field indeed where weights of 2 to 5 tons have to be carried distances under 30 to 40 miles. A wagon carrying such weights has already been made, and a number of orders given on the results of its running. The great saving in time and labour due to their being no loading in and out between the ordinary dray and the railway trucks is a matter of very considerable importance. Under such circumstances the motor-wagon would compete favourably with the railways.

Mr. R. W. BUTTEMER said:—In connection with the subject of the influence of past design on present construction of motor-cars, I wish to call attention to its bad influence, as shown in the survival of useless parts, degenerate representatives of parts necessary in horse-drawn vehicles. Instances: the dashboard, still existent on some types, in spite of fact that no horse is in front to kick up mud, and no reins to be supported; the ends of longitudinal bearers of carriags, often terminating in hooks for the attachment of non-existent traces. The engineer should certainly be the predominant partner in the construction of motor-carriages; but if he has it all his own way the result is not a comfortable car, though probably a fast one, *e.g.*, the Bollée. With regard to other remarks, a clinometer is a most useful accessory. Few of those who talk glibly about a gradient of 1 in 6 or 8 know what such a hill really is. I have experimented with several forms of clinometer: a curved tube containing coloured glycerine which, though dead-beat, was too slow in responding; a suspended pendulum, which was too much affected by vibration; and, finally, have found a mercury gauge the best, an arrangement which was, I believe, put on an autocar about 1870.

Mr. Killingworth Hedges, Mr. T. W. S. Firth, and Mr. P. McManus were also among the speakers, and the following letter from Mr. Theodore F. S. Tinne was read by the Chairman during the evening:—

Hawkhurst, March 5th, 1898.

The Secretary, Automobile Club.

DEAR SIR,—A prior engagement having prevented my attending the meeting at which "Inventions" are to be discussed, I beg to submit the following remarks:—

Having designed a steam-driven motor-car "in the sixties," having always been keenly interested in the subject, having watched the race to Brighton and the procession to Richmond, and being now the owner and driver of a "Daimler" victoria, the several points I now enumerate seem to me to need the attention of inventors.

The motor should be capable of being *started* (as well as stopped) from the seat. It is not only inconvenient and, at times, dangerous to have to get down to start the motor, but it has an undignified and even ridiculous look, as well as, in wet weather, risking the muddiness of the tails of one's great-coat!

It would be better far if we could have a "self-starter," by which the pressing of a knob or moving of a lever should start all off.

Then all fittings should be capable of being reached "from the deck," instead of, as at present, its being necessary to lay down a sack in the mud and lie on one's back under the car.

There should be, in view of the driver, an indicator to show exactly how much oil fuel he has in his tank; and, for electrically ignited, or driven, carriages, how much electricity he has left.

A self-*recording* speed indicator should be easy to design, and might save a driver from the astounding judgment of some policeman, in cases of disputed speeds, if he could show, say by a pencil line on a revolving drum covered with paper, the exact speed he was running at any time on his trip.

* This fund has been further increased by a donation of £5 5s. from Sir Wm. Abdy, contributed through the Automobile Club.

A clinometer could be easily fixed on the car, by which would be indicated, without question, the angle of the slope up or down which a car is going.

For very hilly country a pair of "slippers" could be arranged to drop under the hind wheels at a moment's notice by "touching a button" from the seat, even if it involved the necessity of getting down to pick them up again at the bottom of the hill.

These last, however, are refinements. What has been impressed on my mind most in introducing my autocar to the notice of many friends is the necessity of simplifying all the mechanism to the utmost—to have as few details as possible requiring manipulation, attention, adjustment, and repair—so as to put the whole management of a self moving carriage well within the powers of an ordinary unskilled and unmechanical person. At present, the multiplicity of things to be done, and the almost certainty of being very dirty when you have done them, are great deterrents to many who would be only too ready to possess an autocar if they could do so without incurring an undue sense of insecurity and worry.

I am, Sir, yours faithfully,

Theodore F. S. Tinne.

The Secretary of the Automobile Club has issued a circular giving particulars of the Easter Tour organised by the Club. In it he states:—

It is hoped that every member of the Club will make an endeavour to participate in this tour, if not on a motor-vehicle—on a bicycle, or by horse-vehicle, or by joining the tour at one of its stopping places, all of which are easily accessible by railway.

Ladies and non-members accompanying members will be welcomed to the Club luncheons and dinners on the tour.

I shall be happy to provide you with all possible information as to hotel accommodation, but members will engage their own rooms and places at table.

It is strongly urged that, in order to avoid disappointment, members should engage bedrooms immediately.

The following members of the Tour Sub-Committee will take part in the tour, and will be happy to assist members in every possible way:—Mr. Frederick R. Simms, Mr. Frank Butler, Mr. C. Harrington Moore, and the Secretary.

Members participating in the tour who use photographic cameras are invited to take photographs, and to contribute prints for the Club album.

Members having knowledge of hotels, coach-house accommodation, petrol stores, &c., on the route are requested to kindly give as full information as possible.

The following is a general synopsis of the tour:—

Thursday, April 7th.—1 p.m., luncheon at Club; 3 p.m., start from Club; 8 p.m., dinner at Guildford. Sleep at Guildford.

Good Friday, April 8th.—12 noon, leave Guildford; 1.30 p.m., luncheon at Farnham; 7.30 p.m., dinner at Winchester. Sleep at Winchester.

Saturday, April 9th.—10 a.m., leave Winchester; 2 p.m., luncheon at Fareham; 7.30 p.m., dinner at Chichester. Sleep at Chichester.

Easter Sunday, April 10th.—10 a.m., leave Chichester for Arundel; 1.30 p.m., dinner at Littlehampton; to Worthing (Worthing to Brighton and back); 8.30 p.m., supper at Worthing. Sleep at Worthing.

Easter Monday, April 11th.—9.30 a.m., leave Worthing; (*a*) Direct for London; (*b*) For Tunbridge Wells; 1 p.m., luncheon at Uckfield; 7.30 p.m., dinner at Tunbridge Wells. Sleep at Tunbridge Wells

Easter Tuesday, April 12th.—10.30 a.m., leave Tunbridge Wells; 1 p.m., luncheon at Sevenoaks; 7 p.m., dinner at the Club.

Accompanying the circular is a useful detailed diary and itinerary for the entire tour.

E.P.S. Batteries.—Mr. J. W. Barnard informs us that his engagement as secretary of Electrical Power Storage Company (Limited) having terminated, the Company have appointed him their sole agent in the United Kingdom for the sale of their Q and V types of storage cells. It will be remembered that these types of E.P.S. cells are intended specially for use in connection with carriage, cycle, miners', domestic hand-lamps, phonographs, electro-medical appliances, &c. Mr. Barnard has secured offices at 4, Great Winchester Street, E.C., where he will have every opportunity of meeting the numerous customers of the Electrical Power Storage Company who are interested in this particular branch of its manufactures.

THE PROGRESS OF AUTOMOBILISM.

The Yorkshire Motor-Car Company (Limited), of Bradford, are not wasting time and money in so-called experiments but are developing a steady business, and, if we may be pardoned a "hull," are pushing the motor-vehicle with most satisfactory results to all concerned. They have just completed a very handsome Daimler delivery van for express parcel service for use in Bradford. They are also doing good business in the hire and purchase system with motor-tricycles and sociables.

THE SIMPSON AND BODMAN BOILER.

In our present issue we publish a paper read by Messrs. Simpson and Bodman, on Motor-Vehicles, before the Liverpool Centre of the Self-Propelled Traffic Association. In this paper, which, by the way, is well worth careful study, these gentlemen detail their experiences

Fig. 1.—Simpson and Bodman Boiler.

with various types of boilers, and at length they have designed a type of water-tube boiler, which we illustrate herewith, and which seems to us to possess many good features. The general appearance of the boiler is shown in Fig. 1, while Fig. 2 is a general elevation. The boiler consists of 22 elements, each element being an indented "Royle" tube. This form of tube gives a relatively larger surface per unit length. These tubes are connected up in series, much as in the Serpollet system, but Messrs. Simpson and Bodman employ a differential screw joint union. The generator so formed has a very large amount of heating surface, and, at the same time, is not heavy. The following are the references to the lettering in Fig. 2:—*FWT*, feed water tank; *PS*, pump suction pipe; *HSP*, hand starting pump; *EP*, engine pump; *PD*, pump delivery pipe; *SRV*, spring relief valve; *ISV*, injector stop valve; *FHT*, feed heating tube; *BFP*, boiler feed pipe; *G*, generator; *SP*, steam pipe; *ID*, injector drum; *MSP*, main steam pipe; *MSV*, main stop valve; *FB*, firebox; *F*, funnel.

We hope to give in a future issue the results of trials with this boiler, which is a most ingenious construction.

P

FIG. 2.—SIMPSON AND BODMAN BOILER, GENERAL ELEVATION.

Automobilism in Belfast.—The *Belfast Evening News* understands that a number of motor-cars for passenger and vehicular traffic will be inaugurated in that city early next month. The first experiment for passengers will start from the Bank Buildings to Newtownards and Portaferry, and afterwards to other northern towns, including Ballynahinch, Newcastle, Castlewellan, &c. It is anticipated this novel undertaking will prove a great success, and undoubtedly will be highly appreciated by tourists and the public generally.

Storage Battery Traction.—The equipment of the Ostend railway is on the electric accumulator system, the plant being established in the depôt of the local railway. The line, which was recently described in *L'Electricien*, is 3·1 kilometres long, and is virtually a circular road connecting the Kursal Boulevard, Rogier Station, and the Harbour. The plant includes one compound engine direct-connected to a Westinghouse dynamo, generating 135 ampères at 280 volts, and operating at 650 revolutions. The switchboard is of three white marble sections, with the usual instruments, and commands four accumulator-charging circuits with pressures varying between 240 and 270 volts. The charging of the accumulators is done upon a central track, so that the handling, both loading and unloading, is extremely easy of accomplishment. The complement of each car comprises 12 boxes of nine elements, having a capacity of 140 ampère hours at a 50 ampère rate. The charge lasts from three-quarters of an hour to two hours, according to the demand made upon the battery. As constant use gradually disintegrates the active matter of the positive plates, this is carefully saved in a tank, and eventually used for renewing the battery. This process is several times repeated before the frame finally becomes worthless, when it is recast. Each element is contained in an ebonite vessel, the nine elements being enclosed in a wooden trough, having two bands of copper for contacts. The carriages weigh 7,500 kilogrammes without accumulators or passengers, and have a capacity of 24 seats and 26 standing places. They have no imperial or deck seats. The carriages are lighted by six 16-candle-power lamps each, and are provided with two 18-kilowatt Westinghouse motors, each connected to an axle by reducing gears of one to five. The motors are regulated by a series-parallel controller with spark extinguisher. According to data obtained for three months of active service, the management claims that the expense of this line will be very much below anything so far known in this form of traction, the consumption of coal being shown to be but 1·45 kilogrammes per kilometre-act.—*Electrical Review.*

CONTINENTAL NOTES.

In Austria alcohol-motors are finding increasing favour.

The Paris-Amsterdam race will start on July 3rd, and return on the 11th. The total distance traversed will be 1,104 miles.

The latest Roser-Mazurier omnibus weighs, in working order, 5,280 lbs.; this includes 11 gallons of petrol and a box of tools. The vehicle will carry 15 persons.

The well-known engineering firm of Decauville has decided to engage in the manufacture of automotor vehicles. It has purchased the patents relating to the Guidon motor.

A Company has been formed at Nuremberg, with a capital of 200,000 marks, to work the Lutzki motor patents. The Company is entitled Gesellschaft für Automobilwagenbau.

The Compagnie Générale des Automobiles Livreurs, with a capital of £8,000, and La Société Commerciale d'Automobiles, with a capital of £24,000, have recently been formed in Paris.

The duty or tax upon automotor vehicles in the province of Liége has been fixed at 75 francs for vehicles of four places, 60 francs for vehicles of less than four places, and 10 francs for motor-cycles.

The Compaguie Française de Voitures Electromobiles has been formed under the auspices of La Banque Internationale de Paris and La Compagnie Générale des Voitures. The office of the new Company is at 20, Rue Tailhout.

Messrs. G. Barthélemy and Co. have taken a large place near Place Periere, 13, Rue Descombes, Paris, for the benefit of those who possess automobiles, and the charging of electric batteries can also be effected there. Coach-houses exist, and all is ready for repairing and cleaning.

The Automobile Club of France invites tenders for the supply of speed and distance measuring apparatus, to be supplied to vehicles competing in the various contests the Club is going to organise during the present year. The last day for receiving tenders is April 30th, so inventors must put their best foot foremost.

M. Le Comte de Dion has reported to the Commission of French Customs (Douanes) in favour of imposing a duty on the export of motor-vehicles, because he fears the industry would be transferred from France to this country. He also objects to the publication of patent specifications, because foreign makers will copy ideas.

A future automobilite of distinction will be M. Pierre Hospitalier, the son of the distinguished writer and engineer of that name, a translation of one of the latter's articles appearing in our present number. Young Hospitalier, although only 11 years, can already handle the steering and starting gear in a way which excites the admiration of even experienced *chauffeurs*.

Motor-omnibuses are now used on the road between Mantes and Vetheuil, and between Mantes and La Roche-Guyon, the run between each of the two places occupying 45 minutes and one hour respectively. One of the vehicles is a De Dion and Bouton steam omnibus, which carries 18 passengers, weighs about 4·8 tons, and is provided with an engine of 30 H.P. A petroleum motor-omnibus, constructed by M. H. Tenting, of 46, Rue Curial, Paris, is also engaged on this service. In this omnibus the motor is fitted under the front instead of the rear of the vehicle. The motor, which has, in this case, four cylinders, is capable of developing 16 H.P., the weight of the carriage, complete with its load of 18 passengers, being about 6 tons.

The French Chamber has sanctioned the imposition of the following taxes upon automobile vehicles. In Paris vehicles for two seats pay 60 francs; vehicles of more than two seats 100 francs; in the communes of more than 40,000 inhabitants, 40 and 75 francs; in communes of 20,000 to 40,000 inhabitants, 30 and 60 francs; in communes of 10,000 to 20,000, 25 and 50 francs; in communes of 5,000 to 10,000, 20 and 40 francs; in communes of 5,000 and below, 10 and 20 francs.

The Marseilles-Nice race, although most carefully planned, yet suffered much from the weather, and the concluding portion of the competition, which took place on the 7th, was run in a perfect downpour of rain which had fallen almost continuously for 48 hours. The roads were consequently very heavy and slippery, and tried the machinery of the different systems very rigorously. Fewer than 38 carriages and 10 motor-cycles faced the starter at Marseilles on the previous day, a motor-cycle and a carriage being despatched together at intervals of half a minute. The first day's halt was at Hyères, a distance of 71 kilometres. The competitors left Hyères on Monday morning at nine o'clock for Nice, a distance of 159 kilometres, with very steep gradients, especially between Hyères and Fréjus. A huge crowd had assembled at Nice on the Promenade des Anglais, especially in front of the Méditerranée Club. The following is the result of the race:—1. M. Charron, in a carriage by Panhard-Levassor; 2. M. Bourgières, same maker; 3. M. De Knyfe, same maker; 4. M. Giraud, same maker; 5. M. Koechlin, in a carriage by Peugeot.

COST OF ELECTRIC TRACTION.

According to the *Railway World* the following are the prices for producing current for sale to tramway companies:—

	No.	Average cost (pence).
I.—*Local Authorities.*		
(*a*) Selling over 1,000,000 units per annum	4	1·63
(*b*) Selling from 500,000 to 1,000,000 units per annum	4	1·95
(*c*) Selling less than 200,000 units per annum	20	3·51
II.—*Companies.*		
(*a*) Selling over 1,000,000 units per annum	1	2·44
(*b*) Selling between 500,000 and 1,000,000 units per annum ..	3	2·28
(*c*) Selling less than 200,000 units per annum	12	4·26

Commenting on these figures the *Electrical Review* says:—"We are thoroughly in accord with our contemporary in considering such tariffs as 3*d.* and 4*d.* per car mile or per unit for tramway current to be simply prohibitive under average conditions; the maximum rate fairly chargeable ought not, so far as we can at present say, to exceed 2*d.* in view of the long hours of demand coupled with steady use of current. The momentary variations from zero to maximum, which are sometimes characteristic of a line with sparse traffic, doubtless affect the instantaneous governing powers of the engines, but can hardly be said to make much difference to the steady jog-trot of the recording watt-meter that helps to draw up the bill for current delivered. Nor should they necessarily imply the provision of expensive duplicate plant with greater capital outlay and consequent higher cost, in so far as that is concerned, of current delivered."

According to some comparative calculations of all the costs of installation and operation required by animal, oil-motor, and electric traction, made by the Société des Voitures Electriques, which operates on the Krieger system, it seems that all the advantages as regards economy lie with the electric system. For daily cost of operating cabs this Company gives the following figures:—

For animal traction	15·44 francs.
For a petroleum automobile	13·20 „
For an electric automobile	8·13 „

DOINGS OF PUBLIC COMPANIES.

THE Madelvie Motor-Car Company (Limited), of 67, George Street. Edinburgh, a private Company recently launched in Edinburgh, with a capital of £25,000, for the manufacture of motor-vehicles, cycles, &c., has secured ground to the extent of 5 acres, at Granton, for works. Mr. William Peck, F.R.S.E., &c, is the Managing Director.

New Beeston Cycle and Motor Co. Reconstruction.

THE statutory meetings of the Beeston Cycle Company (Limited) and the Beeston Motor Company (Limited) were held on the 26th ult. at Coventry, Mr. Rowland Hill presiding, there being also present Dr. Iliffe and Mr. S. Gorton (directors), Mr. E. F. Peirson (secretary), and a few shareholders.—The CHAIRMAN recalled to the mind of the meeting of the Cycle Company the steps which were taken last autumn to reconstruct the New Beeston Cycle Company (Limited), and for the formation of two separate Companies—a Cycle and a Motor Company—one object being to get rid of a large number of vendors' shares in the possession of the promoters of the original Company. The capital of the present Cycle Company was nominally £100,000, of which £68,000 was issued. To that had to be added debentures amounting to £35,000, making a total of £103,000; and whereas, at the present time, nearly all cycle companies entered large items for goodwill in their assets, here no such thing was done. The buildings, plant, and stock-in-trade, together with the book debts, cash in hand, and 3s. per share provided by the shareholders, amounted to the total of something over £90,000. He wished the shareholders to understand the great advantages which had been obtained by the arrangements now carried out. The trade had well received the Company's machines, and, with fine weather, he believed the season would prove a good one. The demand for motors continued to increase. He alluded to the recent launching of the Beeston Cycles (Continental) Company, and said the directors thought there was a good opportunity for extending the business in this way, and that they would have been unwise if they did not take advantage of the opening. He acknowledged the loyal way in which the shareholders had stood by the Board, and thus assisted them in rescuing the Company from a position in which success was practically impossible.

At the meeting of the Beeston Manufacturing Company, the CHAIRMAN stated that the nominal capital of this concern was £110,000, of which some £69,000 was absorbed by members of the old company. The vendors of the old Company took £35,000 4 per cent. debentures. The 3s. liability should yield a working capital of £10,000, which the directors considered would be ample for the purpose of the business. The business was of an encouraging character; for whereas during the greater portion of the New Beeston time the motors made were the best that could be turned out under the circumstances, they now had their own works devoted exclusively to the manufacture of motor-cycles. There was now a regular weekly output, and he thought the total volume of trade was likely to be a large one in future. The directors were more confident than ever that there was a great future for the Company.—The shareholders present at the meeting, before leaving, inspected the factory.

G. R. Blot and Co. (Limited).

AT the statutory meeting of this Company, held on the 14th ult., the CHAIRMAN (Mr. Thomas Parker, J.P., F.R.S.E., M.I.C.E., &c.), after the Secretary (Mr. William Aubanel) had read the notice convening the meeting, in addressing the shareholders, said:—The future of the Company is well secured, owing to the fact that they have orders in hand and in view, and a very effective staff to carry out the requirements of the Company. The capital of the Company has been largely subscribed by English and French shareholders, and there are amongst both some very influential people. The Company, therefore, has at its command the capital necessary to meet its requirements. I am glad to be able to say that the French Company, La Compagnie des Accumulateurs Electriques Blot, has been very successful, and has just received an order from the "Secteur" of the Champs Elysées for a battery of 10,000 ampère hours, discharging at the rate of 2,000 ampères per hour—one of the largest batteries in the world, if not the largest. Those who know something of accumulators will understand the magnitude of this one, and I question if there is so large a one at present built. The Company has 15 tons of plates to handle per week, so that we have every reason to hope that we shall do quite as much at our factory at Wednesfield. Your directors are proceeding as quickly as possible with the erection and fitting out of our new works near Wolverhampton, and in a few weeks will be able to commence delivery of accumulators on a large scale. For my own part, I have been connected with accumulators since 1881. There was a notice of my first effort in this respect in the *Electrician* of February 7th, 1882. From this time, as managing director of Ellwell-Parker (Limited), up to 1889 I have developed a very large accumulator business in Wolverhampton. In 1889 I ceased to be a manufacturer of accumulators, but have since that date been largely connected with enterprises in which accumulators have played an important part, and I welcome this Company in their efforts to establish a business in England, and, I believe, upon lines which will be successful. The new Company has everything in its favour—works admirably situated, with every facility for cheap transport by canal, railway, and the like. The freights being so reduced and rent so cheap, it is more than probable that handsome dividends will soon be paid. Situated as our works are, right in the very heart of the electrical world, there is every reason to hope for a favourable result, and I trust that at our next annual meeting we may be able to tell you that we are well and securely on the road to this end, and I hope we shall thoroughly satisfy those gentlemen who have taken an interest in the Company.

Mr. J. COLLEY having thanked the Chairman for the very able manner in which he had conducted the meeting, the proceedings terminated.

London Electric Omnibus Company.

AN extraordinary general meeting of the above Company was held on the 4th inst., for the purpose of receiving the report of the committee appointed at the meeting on December 31st last, Major Flood Page (the chairman of the Company) presiding.

The notice convening the meeting having been read, the Chairman said that at the annual meeting held on December 31st last he, on behalf of the board, proposed a resolution for the appointment of a committee. He would therefore at once call upon the chairman of the committee to address the meeting.

Lieut.-Colonel THOMAS TURNBULL (chairman of the committee) then read the report of the committee, which is as follows:—

"The first business discussed was the Company's present unsatisfactory position, which, in the opinion of the committee, results from the following causes:—(a) By the board having gone to allotment on too small a firmly-subscribed capital; (b) by the payment to the vendors of £6,183 10s. in cash, when the Company had such a very small available working capital; (c) by the board having made an agreement on July 29th, 1896 with Mr. Marshall, one of the vendors, who was also a director of the Company, that only one call of equal to 2s. per share should be made prior to July 31st, 1897. This agreement deprived the Company of the power to raise the capital necessary to work the business; (d) by the loss of capital—firstly, through the failure of Mr. Marshall and his associates ultimately to pay their calls, amounting to £9,737 10s.; and, secondly, to that of other shareholders, amounting to £5,696 19s., making a total deficiency of working capital of £15,434 9s.; (e) by the excessive expenditure upon general charges as shown in the annual report; a portion of this, may, however, have been indispensable in the establishing of this new industry; (f) by the large expenditure in connection with the development of the Sola Accumulator. With an increased working capital of not less than £15,000, and under economical and careful management, expending said capital in building and properly equipping omnibuses, the committee is satisfied the Company has a splendid future before it, with a large earning capacity. Provided the above capital is secured to work the Ward system and Schanschieff Sola Accumulator agreements, which are both valuable, the position of the Company is much better than was represented to the public previous to the annual general meeting. Mr. Ward has agreed with the board and committee to extend his licenses to the whole of the United Kingdom; he to be paid 10 per cent. in cash or shares on any gross amount the Company may receive from the sale of the same in the United Kingdom outside of England, the Company already possessing the licenses for England; the Company also to have the benefit of any and all improvements Mr. Ward may make in relation to electric accumulator traction in omnibuses, cabs, stage coaches, and other public vehicles other than vehicles used on tramways. Mr. Schanschieff's agreement conveys the exclusive right to use his patents for accumulators for omnibuses and cabs for London, with the additional privilege of granting sub-licenses for all public carriages, excepting tramways, for all England, and a right to use any improvements and discoveries that may be secured by the patentee, provided the Company pays cost of securing the patents. Also, the patentee undertakes to supply accumulators for 300 omnibuses at actual cost, and, should the Company decide not to manufacture accumulators, to supply all future orders at a royalty to be fixed by arbitration, the price net to exceed what is usually paid to other accumulator companies. Mr. Spagnoletti attended one of the meetings, and expressed his opinion that the 'Sola Accumulator was most suitable for street traction, because it was lighter and cheaper than the average accumulator, and more economical to manufacture and work.' The committee requested the board to make a practical test of the running of the omnibus, resulting in a trial made on the 5th inst. The entire arrangements for this test were made under the direction of the board, who requested Mr. Spagnoletti and Mr. Schanschieff to take observations, and Mr. Ward to act as engineer. The omnibus carried 17 passengers, and ran out to Hammersmith Broadway from Trafalgar Square and back to Whitehall, a distance of 14 miles, going and returning by circuitous routes. On the outward journey the route lay up Haymarket, one of the steepest grades in London, and the omnibus maintained a uniform rate of speed on this grade. The steering was perfect in every respect, and the control in starting and stopping was thoroughly successful, the omnibus threading its way through the crowded traffic with perfect facility. Mr. Spagnoletti concludes his report thus: 'The result of this trial trip I consider most encouraging and very satisfactory indeed.' The committee find a contract is in existence with the Electric Street Car Manufacturing Syndicate (Limited), of Wolverhampton, its main object being the building of suitable omnibuses in an expeditious manner for this Company. Provided these are secured on advantageous terms, this contract should prove to be to the interests of the Company. The committee having carefully examined the articles of association, are of opinion that these should be suitably amended. The Company has at present at its disposal 119,993 shares ordinary stock unissued. The issue of deferred shares is 80,000 shares of £1 each; these were all given to the vendors. The committee recommend that, provided the consent of the holders of the ordinary stock is secured, some satisfactory arrangement should be made with the deferred shareholders which would have the effect of reducing the capital stock of the Company very materially. This, in conjunction with the securing of the additional capital, would be an important factor in the future prosperity of the Company. In the meanwhile this Company has secured a prominent lead in the great question of electric traction for omnibuses, &c., and the committee feel assured that within a very short space of time this Company's method of accumulator traction will entirely supersede that of horse traction. The committee have gone into facts and figures, and given careful consideration to the probable results from an investor's point of view, and are satisfied that if properly equipped omnibuses are placed on good thoroughfares in London and elsewhere, with regular services, the returns will be satisfactory on money invested, and will bear out the figures as to profits given in the original prospectus. A reduction of expenditure is necessary, and towards this it has been proposed, by the directors themselves, that they should be entitled to only two-thirds of the fees fixed in the articles of association until such time as the Company has paid an annual dividend of 7 per cent. Mr. Ward has voluntarily reduced his annual salary one-half until the Company is able to pay a 7 per cent. annual dividend to its shareholders, when he may resume his former salary, provided the said dividend is arrived at within the limit of his agreement. Mr. Ward has also relinquished his seat at the board. It has been unanimously decided by the board and committee jointly that a sum of at least £15,000 working capital is required for the immediate development of the Company's business. It is proposed to construct 12 omnibuses, and place them on a desirable route, or routes, to be decided. It is estimated that these omnibuses will cost, with complete equipment, the sum of about £9,000, leaving a balance for fixed charges, omnibus stabling, wages, &c., of about £6,000. In the event of providing a station and electrical appliances, so that this Company might supply its own electricity, it is estimated that a further sum of about £5,000 would be required. Though arrangements can at present be made to purchase electricity on fairly reasonable terms, it is thought advisable that this matter should be taken into consideration as soon as the necessary capital is available. The immediate appointment of an assistant engineer is absolutely necessary; this will receive the board's attention. The Company has the right to dispose of the forfeited shares, upon which 10s. has already been paid, or credited as paid. This should prove a valuable asset, and the committee recommend that these shares should be offered (1) to the original shareholders who have defaulted; if so taken up the Company would receive the sum of £15,000; and (2) to the present shareholders as fully-paid shares for the sum of 10s. each, which would yield the sum of £15,935; and (3) in block to any person or persons who would be willing to purchase at a price to be named, or who would advance a sum sufficient for the Company's immediate requirements. Provided the amount required is realised from the forfeited shares there will remain 119,993 unissued shares of ordinary stock, which the proposed development under the expenditure of the £15,000 should also become an asset of considerable value to the Company. The committee feel assured that the future prosperity of the Company, carried out on the proposed lines, will lead to great financial success, and trust this policy will be heartily endorsed by the shareholders."

Lieut.-Colonel TURNBULL, in moving the adoption of the committee's report, said he thought there had been mistakes of judgment on the part of the board; but they also recognised the great difficulties the directors had had to contend with, owing to the small capital they had at their command, and through the shareholders not having met their calls. It was important that the Company should be run on business principles, and the first thing necessary was to provide sufficient capital to build omnibuses. There was a contract in existence with the Street Car Manufacturing Syndicate, of Wolverhampton, which the committee thought could do the work necessary in a satisfactory manner. The Company possessed a good system of steering in the Ward system, and a good accumulator, lighter and cheaper to manufacture than any other.

Mr. J. ELLIOTT CONDICT, in seconding the resolution, said the action of the board in their development of the Sola Accumulator had been very satisfactory, and he did not think that they had spent an unnecessary sum of money in that direction. The Sola Accumulator was half the weight of any other accumulator in the market. The test of the omnibus lately was a most satisfactory one, because they were able to find the exact amount of voltage and the number of ampères used on the track. Having this data before them, and knowing that they could purchase the current from electrical companies at the rate of 2*d.* per unit, they were able to verify all the statements that had been made in the prospectus. They were consequently able to feel that in this omnibus business they were standing on good solid ground.

The CHAIRMAN expressed satisfaction at the report of the committee. With regard to the agreement made with Mr. Marshall, the promoter, not to make a call, the board did not know much about his financial position, but from the representations that were made to them they felt they were justified in making this arrangement. He could bear testimony to the large amount of work done by the committee, and it was a matter of satisfaction to him that the committee had given the cachet of their approval to what the directors had done.

The resolution was then put to the meeting, and carrie unanimously.

On the motion of Mr. Brooks a sum of £100 was voted to the committee for their services, and the proceedings terminated.

The report of the committee of this Company forms, says the *Electrical Review*, pretty reading, and the practical test which Mr. Spagnoletti considers most encouraging and very satisfactory only goes to show he must be very easily satisfied. Mr. J. Elliott Condict, too, boasts of the satisfactory nature of last month's test, because, forsooth, they were able to find *the exact amount of voltage and the number of ampères used!* Can it be possible that these figures have never been ascertained previously? The results obtained with the 26-passenger 'bus, carrying, however, only 17, have been submitted to us, and, briefly stated, are as follows:—The vehicle ran from Trafalgar Square to Hammersmith Broadway, and back to Whitehall, a distance of 14 miles, in 1¾ hours, inclusive of a 17 minutes' wait at Hammersmith. The day was perfectly dry, the roads clean, and with one exception, viz., Haymarket, the route to Hammersmith is fairly level. The return was made on a road still more favourable for the 'bus, but had the day been wet, with greasy streets, it is doubtful whether it would have reached home without assistance. Readings of current and voltage were taken every 5 minutes, the ampères averaging 39 and the volts 230, or an average of 12 H.P. electrical. It is stated that at the end of the run enough electrical energy remained in the battery for 11 miles further, but we need not, at the moment consider this. The question is, whether there is not a great loss of electrical energy somewhere; 13,000 watt-hours taken from the battery during a trip of 1¾ hours means no less than 9 units per hour, a result which speaks for itself.

This Company's return was filed on January 21st. The capital is £250,000 in £1 shares (80,000 deferred). All the deferred and 17,818 ordinary have been taken up, and the deferred are considered as paid; 19*s.* 6*d.* per share has been called on the ordinary, and £33,274 2*s.* 6*d.* has been paid (including £17 15*s.* paid in advance); £15,500 9*s.* is in arrears, and £16,520 8*s.* 6*d.* has been received on 32,189 forfeited shares.

The Epstein Electric Accumulator Company (Ltd.) (in Liquidation).

MR. P. W. NORTHEY, liquidator, receiver, and manager of this Company, has issued the following circular from 28, Victoria Street, Westminster, S.W.:—"As you are probably aware, an action was instituted in the month of July last on behalf of the first debenture holders, and in such action I was appointed receiver and manager, and have in that capacity continued to carry on the business of the Company. Subsequently, an order was made for the compulsory winding-up of the Company, and I was appointed liquidator in such winding-up. An offer has been made for the purchase of the Epstein Company's assets by a new Company, which proposes to take over the business as a going concern. The terms of purchase, while not immediately satisfying the entire claim of the first debenture holders (£6,000), give them such interest in the new Company, coupled with a guarantee of minimum working capital, that the offer is likely to receive favourable consideration on their part. As to the owners of the second Epstein debentures, these will have the option of applying for fully-paid ordinary shares in the new Company, not exceeding in face value the amount of their present holding in second debentures at a discount of 50 per cent. Any such options not exercised by owners will be held at the disposal of other second debenture holders who wish to participate in the new scheme beyond their present holding. The actual assets of the Epstein Company, after collection of outstanding accounts, will be approximately £2,000 in cash, besides:—

	£	s.	d.	
Plant ..	8,164	17	5	as nominally valued in books on January 1st, 1898.
Stock ..	3,296	17	11	
Patents ..	70,050	0	0	

While the before-mentioned offer is under consideration, I desire to invite competitive proposals which may be productive of better results, and I shall be glad to give any desired information with a view to the receipt of ulterior proposals before closing with the one received, which will be open for acceptance till February 26th."

We believe this proposal is still open.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

	Capital.
Automotors, Ld. (40, Holborn Viaduct, E.C.)	£100
Beeston Cycles (Continental), Ld. (Quinton Works, Cheylesmore, Coventry)	15,000
British Wagon Co., Ld. (22, Moorgate Street, Rotherham)	700,000
Coventry Accessories, Ld. (Triangle Chambers, Martineau Street, Birmingham	5,000
Gloria Cycle Co., Ld.	100
Hopkins, Taylor, and Co., Ld. (Birmingham)	2,000
International Engine Patents Developments Co., Ld. (33, St. Swithin's Lane, E.C.)	3,750
Langdon-Davies Electric Motor Co., Ld.	70,000
Manchester Acetylene Gas and Carbide Co., Ld. (St. Simon Street, Salford)	40,000
New Coventry Co., Ld., (Quinton Works, Cheylesmore, Coventry)	15,000
New Power Syndicate, Ld.	15,000
Pneumatic Beer Pump Co., Ld. (2, John-Dalton Street, Manchester)..	5,000
Self-Charging Electric Traction Co., Ld. (40, Holborn Viaduct, E.C.)	100
Taxameter Syndicate, Ld.	20,000
Windsor Cycle Co., Ld. (3, Great Turnstile, High Holborn)	1,500

REVIEWS OF BOOKS.

"Transactions of the Liverpool Engineering Society." Vol. XVIII. Edited by R. C. F. ANNETT, Assoc. Inst. C.E.

THE Liverpool Engineering Society, we need hardly say, is one of the most important and flourishing provincial professional bodies, and hence the papers read by the members on various engineering matters, and which constitute the Transactions, are not only of interest but of considerable practical value. The present volume is no exception to this rule. In the Presidential address, by Mr. S. B. Cottrell, on Railways, the following passage occurs; we reproduce it here, as it illustrates the attitude with which many people even now regard automobilism:—"What strikes us at this date (1825) as most remarkable is the difficulty met with in persuading the public that the idea of railways was more than hallucination of insanity. Thomas Gray, of Nottingham, on seeing a train of coal wagons propelled by steam along a railroad track in the North conceived the idea of applying the invention to the purposes of locomotion generally. From that time he persistently agitated the subject in spite of every discouragement, with the common opinion that he, poor fellow, was not quite himself. It was undoubtedly a result of this agitation that when the business men of Liverpool and Manchester turned their attention to a means of transit other than the canals, the railway at once suggested itself. Even then, except by the promoters, among whom appear names highly honoured in Liverpool, the project was laughed at. Such was the feeling in the country districts, when the affair became known, that George Stephenson had to make his first surveys for the line by stealth. On one occasion the mob attempted to 'duck' him. Landowners fiercely warned him off. It is not surprising in these circumstances that his surveys did not prove quite accurate; and on this pretext the Bill was thrown out, and the inevitable slightly delayed. There was a fierce fight, too, with the vested interests of the Canal companies, who naturally played upon public prejudice. The contest was obstinately renewed over every fresh scheme of railway enterprise. The Great Western Bill, introduced in 1833, was opposed by the authorities of Eton as injurious to the discipline of the school and dangerous to the morals of the pupils; and when the Bill was lost, public meetings were held at Oxford and elsewhere to celebrate its rejection. The opposition, however, received a terrible shock from the success of the Liverpool and Manchester enterprise. The assembled thousands who came from all parts of the country to witness the preliminary trials at Rainhill, gazed on the 'Rocket' and the 'Novelty' with a wonderment which became something akin to consternation when the 'huge bulks' were seen moving at a speed which, according to a witness of the affair, 'wearied the eye and excited the brain.' The then Earl of Derby, a bitter opponent, came down to rejoice over the expected failure, but was disappointed, and when the line was formally opened, the Duke of Wellington, as one of the spectators, and guarded by a posse of special constables (owing for the moment to his unpopularity), even refused to enter a railway carriage until thirteen years afterwards." It is interesting to note that the present Earl of Derby is the President of the Liverpool Centre of the Self-Propelled Traffic Association. "Some Notes on Railway Construction," is an interesting account of the difficulties of construction that occur in unfavourable localities. "Water-Tube Boilers," by Mr. G. L. Benton, is a distinctly useful paper, and one that may be used with advantage by those who think about employing such boilers for automobiles. It may be noted that there are no less than 25 recognised types of water-tube boilers to select from. There is a good paper on "Mechanical Refrigeration," by Mr. J. Wemyss Anderson, and one on a similar topic by Mr. Bannister, who, by the way, is a Member of the Council of the Liverpool Centre of the S.P.T.A. Another good paper is on "Sewage Sludge Removal," by Mr. J. Corbett. Space forbids us to deal at large with this interesting and instructive volume of engineering literature. It is well worth quiet study.

"The Essentials of Gearing." By GARDNER C. ANTHONY, A.M. (D. C. Heath and Co., Boston, U.S.A. 1897.)

THE modern technical student does not lack either books or instructors. As one of the latter, Professor Anthony occupies a deservedly high place, while as a writer of the former he is no less well known. The present work on gearing bears strong internal evidence that it has been written with a full knowledge both of the subject and of the student. Many otherwise excellent treatises fail of general acceptance because the writers lack a knowledge of student nature. One can spend much time—not altogether profitably—in studying the principles of wheel gearing: and as presented in the larger works one reads much that, from the practical point of view of the draughtsman, is of little use. Professor Anthony has contrived, in the course of some 80 pages of matter, accompanied by 15 separate plates, to say as much about gearing as will satisfy all but the very advanced mathematician. After some preliminary definitions of terms, assisted by sketches, the various curves are described, together with the method of tracing or drawing them. The theory of Cycloidal Action is, while fully, yet simply, treated of, and the same remark applies to the theory of Involute Action. The chapter on Annular Gearing contains about the best description of this species of toothed gearing we have seen; the limitations and practical considerations being clearly stated. Bevel gearing is thoroughly well described. A table, containing all the elements for shafts at 90° apart, should, we think, prove extremely useful. Although it is customary to tabulate such elements, we quite agree with the author that the most feasible method for the acquirement of a working knowledge of the theory of gear-teeth curves is by a graphic solution of problems relating thereto. But it requires much time on the part of an instructor, and is very difficult for the student, to devise suitable examples which, while fully illustrating the theory, shall involve the minimum amount of drawing. It has been the aim of the author to overcome these difficulties by the presentation of a series of progressive problems, designed to illustrate the principles set forth in the text. An interesting account of various odontographs is given. These means of describing teeth are not so much used here as in the United States. In addition to the purely theoretical aspect of gearing, many valuable hints are given on the practical questions relating to drawing teeth, &c. The work is very well got up, the printing and the plates leaving nothing to be desired.

"The Universal Electrical Directory" (Berly's). (Alabaster, Gatehouse, and Co., 4, Ludgate Hill, London, E.C.). Price 6s.

To all engaged in the electrical industry this work may be said to be indispensable. We notice that the proprietors and publishers do not confine their work to giving mere lists of names and addresses, but give many particulars of the industry in general such as must be very serviceable to the large number of people who are either shareholders in electric light companies or ratepayers interested in municipal lighting and traction schemes. Needless to say that, owing to the rapid growth of the industry, it has been necessary to enlarge the book, which now consists of 1,180 pages. It now contains the names of the members of the electrical and kindred industries throughout the world, and the British Alphabetical Section now comprises about 9,918 distinct names, the Continental 7,872, the American 4,080, and the Colonial 1,924, making a total of 23,794—approximately 1,136 names of individuals and firms more than were contained in the book for 1897. For simplicity and facility of reference it is divided into four groups—viz., British, Continental, American, and Colonial—which are again subdivided into alphabetical and classified sections. In the case of the British a geographical section is given, making in all nine subdivisions. The printing and get-up are also much better than have been the case with former issues.

"Willing's British and Irish Press Guide." (Mr. James Willing, 125, Strand, London.)

This work is now in the twenty-fifth year of its age, and there is indication of its utility and importance, and also of the growth of journalism. It is only by turning over the leaves of such a work as this that one realises the vastness of the enterprises associated with newspapers; while to think that the large number of newspapers shows no tendency to diminish, but, on the contrary, is steadily increasing, is evidence of the growing literary intelligence of the public. On examining the work before us we naturally sought for The Automotor. It was not under the heading of "Motors," nor "Horseless Vehicles," nor "Engineering," but it is placed in the list of papers relating to cycling. This is an error which only needs to be pointed out. The book is distinctly useful to all connected with the Press, and especially to advertisers.

The Yachting Monthly Magazine.—This is the first number of a new magazine emanating from the *Yachtsman* Office. There are a number of interesting "yarns" in it, and some good descriptive writing, but the tone throughout is extremely amateurish, and the professional nautical automobilist will find but little to interest him. The best article is by Mr. E. Horn, on the probable renewal of Schooner Racing. The letterpress is good, and the illustrations also. The magazine is susceptible of considerable improvement in its literary matter, but one must not be too hard on a first number.

CATALOGUES.

Mr. H. Ronnebeck, of Middlesbrough, has sent us his catalogue of steel and iron girders, bars, channels, &c. We observe that the lists are very copious.

Messrs. C. A. Parsons and Co., of Newcastle-on-Tyne, have issued a new descriptive and illustrated catalogue of their well-known Turbo Motor, which was recently described in our columns. This special motor is already very largely used for electric lighting. The catalogue also contains illustrations of the various other appliances connected with naval automobilism made by this firm.

One of the most attractive catalogues we have seen for some time is that of Messrs. Alley and Maclellan, of Glasgow, the makers for Great Britain of the "Sentinel" (Westinghouse) high-speed motors. This cataloge is a useful one to have, as it contains much information of a practical kind. We do not see why the remarkably compact engine made by this firm should not be used for motor-vehicles. A little alteration to some of the parts, and the addition of another eccentric, would render this quite possible.

We have received an excellently well-written catalogue from the Mirlees, Watson, and Yaryan Company, of Glasgow, describing their water-tube boiler. This boiler consists essentially of three upper horizontal steam and water drums, connected by three series of tubes to one lower horizontal drum, which latter serves also as a mud drum, where solids originally suspended in the feed water or thrown out by the evaporation may be deposited. A very high evaporative efficiency is obtained in this boiler owing to the heating surface being in the form of tubes. The transmission of heat across the metal is, therefore, rapid, and takes place with lower differences of temperature than are necessary where the surface is in the form of heavy plates. The hottest gases are applied at the lower and colder portions of the front section of tubes. A very rapid transference of heat to the water thus ensues, and, what is of equal importance, a vigorous circulation of the water is set up and maintained. The circulation is rapid, complete, and continuous, not being impeded by headers, although the tubes are sufficiently inclined to prevent "geyser"-like action. The back section of water tubes is an "economiser," in which the feed water, descending slowly, has time to absorb heat from gases which have already done their principal work in the generation of steam in the front sections.

We have also received *Industries and Iron*, the *Practical Engineer*, *Indian Engineer*, the *Journal of Acetylene Gas Lighting*, the *London Chamber of Commerce Journal*, the *Machinery Market Review*, *La Locomotion Automobile*, *La France Automobile*, *Les Sports*, *L'Automobile Illustré*, the *Engineering Magazine*, *L'Energie Electrique*, *Horseless Age*, *American Wheelman*, *Cyclist*, &c.

Motor-Car without a Light.—On March 8th, William Syers, of Coventry, was summoned for driving a motor-car without a light on the Coventry Road on the 27th ult. A police constable proved the case. Defendant did not appear. He was fined £2, including costs.

Sub Judice.—Mr. Justice Stirling, on February 18th, fined the editor of the *Stock Exchange Gazette* £20 for contempt of court in commenting in his journal on a pending action, involving issues of fraud, brought by a Mr. Greenwood against the Leathershod Wheel Company. The editor pleaded youth and inexperience and ignorance of the law. He apologised to the Court, and agreed to insert an apology in his paper. He also undertook to comment no further on pending litigation.

CALCIUM CARBIDE AND ACETYLENE.

So many of our readers have addressed inquiries to us regarding acetylene—the new illuminant—that the following information will no doubt be serviceable:—

Acetylene was discovered by the great chemist Davy in 1836, who found that in the reduction of potassium from potassium carbonate a compound of potassium and carbon was formed which, in the presence of water, decomposed, producing acetylene. This gas was by him called "klumene." Acetylene is also produced by the decomposition of sodium carbide, and also by the electric arc in an atmosphere of hydrogen. That it was a powerful illuminant was well-known, but the difficulties of its preparation rendered its production of little use save as a laboratory demonstration.

With the introduction of high temperatures, whether produced by the combustion of various gases or by the electric arc, chemistry has assumed an entirely new aspect. The most refractory substances can now be resolved, and other ones formed. Thus Wöhler, by heating at a high temperature an alloy of zinc and calcium with carbon, obtained calcium carbide, and from the latter, in the presence of water, acetylene. The chemical reaction being—

$$Ca + C_2 = CaC_2.$$
$$CaC_2 + H_2O = CaO + C_2H_2.$$

Notwithstanding the discovery of calcium carbide, acetylene did not possess any commercial value owing to the high price of calcium.

The electric furnace, however, enabled Moissan in 1889 to produce calcium carbide much more easily, but still at great cost. He found that calcium carbide was formed by the action of the calcium vapour from the quicklime lining of the furnace in which projected the two electrodes. He fully studied the properties of the carbide, and described them. Simultaneously Mr. Wilson, of Spray, U.S.A., independently discovered that calcium carbide could be produced in the electric furnace. His discovery was, however accidental. He was seeking to produce something else, and threw away into a stream what he thought a useless by-product. He observed that on its coming into contact with water a violent effervescence ensued with the evolution of gas, which, on ignition, burnt with an intensely white light. The gas was acetylene. So valuable is the latter as an illuminant that means were sought to produce calcium carbide on a sufficiently cheap scale to render the use of acetylene a commercial possibility.

Calcium carbide is a hard, shiny crystalline substance of a brownish-red colour; its specific gravity is 2·262. It is practically insoluble in most reagents, but in presence of water it decomposes, as seen by the foregoing equation, into acetylene (C_2H_2) and lime (CaO). Theoretically 1 lb. of carbide requires ·525 lb. of water for its decomposition, and this should yield 1·1563 lb. of lime and 0·4064 lb. of acetylene, measuring 5·5857 cubic feet at 0° C. In practice, however, owing to losses and impurities, 1 lb. of carbide yields 5 cubic feet of acetylene. Upon decomposition 1 lb. of carbide gives 900 British thermal units, and this heat has to be considered in designing generating plant, owing to the low temperature at which acetylene is decomposed.

Calcium carbide acts as a reducing agent to many oxides, and alloys of calcium with most metals can now be obtained. Calcium carbide is manufactured by heating lime (60 per cent.) and carbon (coke) (40 per cent.) in an electric furnace. On starting the current an arc is formed, and the intense heat of this meets the two substances producing the carbide and (see equation above) the carbonic monoxide which burns as a gas with a blue flame. Very heavy current is required for the reduction, as much as 1,700-2,000 ampères at 100 volts; 2·2 H.P. hours are required to produce 1 lb. of carbide. After allowing for various losses it is found that 7,500 electrical H.P. hours are required for the production of 1 ton of carbide. This means that carbide can only be produced when the power can be obtained for little or nothing, hence the factories, in all cases, derive their power from high waterfalls; the idea of producing carbide from electric furnaces in which the current is produced through a steam-engine and dynamo being utterly out of the question. At present the price of carbide is about £16 per ton for large quantities.

Acetylene is an invisible evil-smelling gas, very irritating when inhaled, especially if at all impure. It is soluble in acetone, alcohol, and paraffin, the two latter absorbing 6 and 2·6 times their volumes respectively. Its density is 0·91. Its theoretical calorific power is 336·5 calories. In practice the calorific power is but 397 calories, the difference being due to the fact that acetylene is an endothermic compound, that is, during its formation heat is absorbed and this heat is again set free. When it is decomposed the liberation of heat, especially in the case of liquid acetylene or compressed acetylene gas, invests the use of acetylene in either of these forms with a certain element of danger. According to Professor Lewes, R.N., of the Royal Naval College, at any pressure up to two atmospheres acetylene is perfectly safe from any explosive action, *per se.* At higher pressures, however, a red heat will induce explosion through the whole volume of the gas, this being due to the revolution of the acetylene into its constituent elements, carbon and hydrogen, with the liberation of the endothermic heat stored in it. When burnt with 50 per cent. of oxygen an intense heat, 4,000 C., is produced. The gas freezes at −81 C., it ignites at 500 C., and decomposes at 780 C.

As an illuminant acetylene surpasses all other gases in purity and whiteness; it gives 240 C.P. per 5 cubic feet per hour under the most favourable conditions. In practice 30-40 C.P. are obtained with burners consuming about 1 cubic foot of gas per hour. If the burners were more suitable much better results could be obtained. As regards cost, according to some recent researches acetylene is as cheap as coal gas at 2*s.* 6*d.* per 1,000 cubic feet if burnt in a flat flame. It is thus from its high illuminating power and from its ease of manufacture particularly suitable for isolated mansions, country houses, railway stations, &c.

We shall in a future issue more particularly deal with acetylene as a motive power.

THE ALLAN ACCUMULATOR.

An accumulator which is likely to attract a considerable amount of notice in the traction world is being placed on the market by Messrs. Allan and Adamson (Limited), of 88, Tabernacle Street, E.C. This is the Allan accumulator, whose chief features are;—(1) The proper and effective support of the active material in the plate without the use of a heavy lead supporting frame. (2) Provision for expansion of the plate, to avoid buckling or bending. (3) Effective surface contact over the whole plate between the active material and its supporting frame.

The Allan accumulator plate consists of a hollow frame or envelope, with its edges perforated, and its sides constructed of lattices extending from edge to edge, the edges of the lattices being bevelled. This frame is filled with the active material in the form of a paste, which fills up the centre and keys itself into the two sides of the frame by the bevelled edges, and as these are bevelled towards the inside the active material is effectually locked within the frame, forming a solid block or cake of material in contact all over its surface with the sides and bevelled lattices. The perforations at the edges of the plate allow for expansion of this solid block, and prevent buckling. The effect of this construction is such that the completed plate is a mechanically sound article, whilst the active material cannot fall out, and is in direct contact at all points with the frame. There are consequently no pellets or discs of active material to drop between plates, whilst the excellent contact between the frame and the active material is just where it is required, namely, on and a short depth below the two surfaces. The construction of both + and − plates is similar.

It has been found from careful and lengthy tests of these accumulator cells that they will discharge at any convenient rate and can even be short circuited without harm; and, moreover, they are very free from sulphating and entirely free from buckling. The chief advantages derived from the plate are:—High capacity and discharge; mechanical strength and durability; lightness; freedom from buckling and sulphating.

These important points render this accumulator very suitable for traction purposes, and we understand it has been found from independent tests that Allan cells of standard size will give the same capacity as other cells, but at half their weight and about two-thirds their size. If this claim is substantiated by practical tests, the cell will have a great value, as it will be an ideal one for motor-cars, cabs, &c.

An accumulator which will stand the rough work and handling on motor-car work is, of course, suitable for all other purposes. The makers of the Allan accumulator are prepared to prove the capabilities of their cells by actual tests and trials, and are especially desirous of opportunities for proving their value in actual work in vehicles of every description.

CORRESPONDENCE.

**** We do not hold ourselves responsible for opinions expressed by our Correspondents.*

**** The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion or containing queries.*

AUTOMOBILE CLUB BELGE.

MONSIEUR LE RÉDACTEUR,—Nous vous prions de bien vouloir insérer dans votre estimable journal le communiqué suivant:—

L'Automobile Club de Belgique vient de prendre excellente mesure qu'accueilleront avec joie tous les chauffeurs Belges; il s'agit de l'organisation d'une série d'excursions de propagande décidée par sa commission du Tourisme, excursions qui auront lieu de quinzaine en quinzaine. Les dates choisies sont:—le 20 Février, Pont de Soignes; le 6 Mars, à Tervueren; le 20 Mars, à La Hulpe, par les quatre bras. À Dimanche prochain donc, rendez-vous Place Royale, pour la première sortie à 9 heures du matin. En cas de mauvais temps l'excursion est remise au Dimanche suivant.

Veuillez agréer, Monsieur le Rédacteur, l'expression de mes sentiments distingués.

Comte F. DE VILLEGAS DE SAINT PIERRE,
Le Secrétaire Général.

[We have pleasure in publishing the above.—ED.]

THE ENLIGHTENED PRESS.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—Noticing the usual remarks of our general Press, should they see a motor-car standing, we are much surprised to have seen no mention of a strange sight that met our view the other day in the Kennington Road; within 200 yards we noticed a four-horse 'bus, a White's ginger-beer van, and a Parcel Post van, all broken down at the same time. Surely this is of as much interest as one motor-car standing whilst its owner does business, yet not a word of this can be found in our enlightened Press.—Yours faithfully,

THE LONDON MOTOR-CAR WORKS CO. (LTD.).

Hammersmith, *February 15th*, 1898.

THE MOTOR-CAR ATTACHMENT COMPANY.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—I hope it is not asking too much to supply me with the name of the patent, but preferably the date and number of the patent, under which the Motor-Car Attachment Company are working? Please insert your reply amongst the answers to "Motor-Car," in your next publication of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL, and you will oblige,—Yours truly,

A. MITCHELL.

Longside, Aberdeenshire, *February 10th*, 1898.

[We do not know the Company under this name, nor do we know what patents they own. All our most recent information on such matters will be found in our AUTOMOTOR POCKET BOOK.—ED.]

BRITISH MOTOR SYNDICATE AND ITS CLAIMS AS REGARDS PATENTS.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—It is known that this Syndicate claim all controlling patents, or master patents, for petroleum engines used for propelling road carriages. It is quite possible that the broadness of the claim and the somewhat threatening advertisement in a contemporary may have prevented some firms from going in for the manufacture of motor-cars. That the greater part of these claims are groundless may be proved by any one who has time to make a search at the Patent Office.

Dalton and Kenworthy's patent, 3,467 of 1879, relates to explosion engines for tramways, locomotives, *wheeled vehicles*, canal boats. A carburettor is shown for producing petroleum vapour.

Hardaker's patent, 2,290 of 1880, relates to a small carriage driven by a gas engine, the charge being fired by an electric spark. Of course these patents have now lapsed, so it is difficult to see how the British Motor Syndicate can have the audacity to continue their threatening advertisements.—Yours, &c.,

JOHN HENRY KNIGHT.

Barfield, Farnham, *February 23th*, 1898.

[The above instances are not the only ones, we believe, of a similar character in connection with the British Motor Syndicate Patents. The current price of this Syndicate's shares, issued at £3, is a fair criterion of the real value placed upon these patents by the public. The Syndicate, however, seems to have got hold of a rather more valuable asset recently by the appropriation of the much-respected title of our JOURNAL in connection with the "Automotor" vehicles advertised to be manufactured "under special license from the British Motor Company."—ED.]

MESSRS. SIMPSON AND BODMAN'S PAPER ON STEAM ROAD VEHICLES.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—We have been much interested in the paper written by Messrs. Simpson and Bodman and read before the Self-Propelled Traffic Association, as we perceive that there are others going through a similar course of experiments, *mutatis mutandis*, steam for oil, to those we have already been though chiefly before the new Locomotives Act came into force. All our experiments were made with oil and not with steam, but as to the means and gear for transmitting the power, as to the construction and suspension of the framing and car, the methods of steering, and the brakes, we had to encounter and solve similar problems to those described by Messrs. Simpson and Bodman in this the brief history of their troubles.

As we were probably the only firm in this country building cars before the new Act came into force (we were building in the winter of 1895), and certainly the only firm building oil motor-cars, perhaps a few observations of ours upon the paper will not be out of place. We would observe "right here" that in the use of the word oil we mean petroleum oil, not mineral spirit. The application of the word oil to the mineral spirit motor was a company promoting dodge to mislead the public. It was feared that the public would not look at a mineral spirit motor.* They knew benzoline, and had never called the benzoline lamp an oil lamp.

Messrs. Simpson and Bodman complain of the joints in their boiler giving out, we have not had any difficulty whatever in this way; joints remain as sound in our oil-motor on the cars as in the fixed oil engines. We next come to a somewhat surprising statement. "It is not much trouble to push the car a little to get right for starting." We fear that Messrs. Simpson and Bodman have another extensive series of experiments before them if they are going to take this for granted. Imagine having to get down to push your car before you can start it. This will be bad enough on the level, but suppose you had to start on a hill. Further, imagine that you are starting in the midst of dense traffic in a city—or, say, in the city.

"We were determined, at all costs, to avoid jack-in-the-box gear, which is liable to get a twist and fire, is heavy, and is not by any means efficient in transmitting the power on (*sic*) corners." We rub our eyes, and read it again and yet again. We can only suppose we have been unusually fortunate. We had thought if anything had been sufficiently demonstrated it was the efficiency and usefulness of the properly-constructed balance-gear box. We have not seen any liability to "twist or fire," our gear is very light for each size, and is perfectly efficient in all ways. The balance-gear box has, however, one disadvantage, its expense, assuming the gear is cut, and for this reason chiefly, as also for the fact that it usually requires the use of a tube surrounding the shaft to which it is attached, a substitute should be sought. The whole of that commencing paragraph on the "construction of the car and framing" shows us conclusively that Messrs. Simpson and Bodman have yet a good deal of expensive experimenting before them, but our remarks on this point might run into a paper.

* We note that your esteemed contemporary, the *Autocar*, still uses the word oil when it means benzoline or mineral spirit.

On the question of oak *versus* steel framing for parts of the vehicle we must say we have a good deal of sympathy with what Messrs. Simpson and Bodman say, although this would not be endorsed we expect by any other engineers than those who have experimented with motor-vehicles. With regard to the advantages of liquid fuel for steam boilers, we had thought this had been demonstrated by one firm at least; in any case we have made burners for kerosine that would use one gallon per hour, which were perfectly reliable, and which made but a very slight noise. Messrs. Simpson and Bodman have selected, and stand by, steam as the propelling power for motor traffic; we are, on the other hand, the advocates of oil. There will no doubt be a rivalry between the two sources of power until the time when, as we believe, oil, used in an internal combustion engine, will be so conclusively demonstrated the superior for road locomotives that steam will have no chance in the competition between the two. Messrs. Simpson and Bodman offer us a little proof for our conviction in the following paragraph:—

"The commercial points of a self-propelled vehicle that an intending user should require are, in our opinion, and as the result of careful consideration: A prime cost about equal to three and a-half times the prime cost of a horse lorry capable of moving the same load, with all its horses and appointments; a depreciation account and repair bill not exceeding 33⅓ per cent. per annum of the prime cost to keep it always in the highest condition."

We think Messrs. Simpson and Bodman's figures fairly accurate as to price of the lorry mentioned, since we are in a position to supply oil-motor lorries to carry 1 ton of goods at £350; but with the next item we think we can show Messrs. Simpson and Bodman that at the very outset of their experiments they started with a wrong assumption. In their first paragraph they say, "In deciding to confine our researches to steam as a motive power." They apparently assumed, probably not knowing much of the internal combustion engine, that the steam-engine was the more suitable power. It is our conviction that for all vehicles carrying weights up to 2 tons the steam-engine cannot compete with the oil-engine, and we will employ some of Messrs. Simpson and Bodman's figures in support of our view.

"A depreciation account and repair bill *not exceeding* 33⅓ per cent. per annum of the prime cost." 33⅓ per cent.! If it really works out like this, we fear very much for the future of steam automobilism. We allow less than half this amount, 15 per cent., and then believe it allows a margin for some accidents. As far as we can arrive at it from the figures given, the cost per ton-mile for motive power with steam is three-farthings; the cost per ton-mile with our oil-motor is only one-third of a penny. These figures include fuel, lubricant, and water only in each case.

Then, whereas the steam boiler and motor would require more or less continuous attention, the oil-motor would not require a further thought after starting for the day's run. There would, no doubt, be a more rapid depreciation of the boiler than of the oil-motor, and there would be also a certain amount of danger with the steam-boiler (especially after a few years' use), while there would be none with the oil-motor. To recapitulate briefly, on the points of running, cost, attention, depreciation, danger, handiness, and, in all probability, first cost also, we think that the advantages of the oil-motor heavily outweigh those of the steam boiler and motor.—Yours faithfully,

Roots and Venables.

Westminster Bridge Road, London, S.E.

CYLINDERS AND SHAFTS OF MOTOR-VEHICLES.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Can you, through your journal, enlighten me upon the following points, viz.:—Is it true that all the most successful oil-motors have vertical cylinders? If so, what is the reason? In the Automotor and Horseless Vehicle Pocket-Book you give a formula for finding the weight of the fly-wheel rim for an oil-motor. Now, by this formula I make the weight of rim for a 5 I.H.P. or 4 B.H.P. oil-motor, 2-cylinder, at 700 R.P.M., fly-wheel 12 inches mean diameter, come to 159 lbs. But the Panhard and Levassor 4 B.H.P., at 700 R.P.M., only weighs 166 lbs. complete, and Peugeot's same power motor weighs but 198 lbs. How is this? What would be the weight of fly-wheel rim for my motor? Is a 1¼-inch steel crank-shaft large enough for above motor? You do not give any formula for crank-shafts of oil-motors in the Pocket-Book. I propose cooling the circulating water by pumping same through thin copper tubing placed under car-body. How can I arrive at the number of square feet of cooling surface required for a 5 I.H.P. motor? If you could answer the foregoing I should be greatly obliged.—Yours truly,

B. A. Payne.

Netley, Old Christchurch Road, Bournemouth.

[No; the object in fitting vertical cylinders is to save fore and aft space; but, as a rule, vertical cylinders are preferable for wear and tear and the avoidance of unequal stresses. The rule for fly-wheels is one deduced from theory and practice: it gives the least weight of a wheel necessary to avoid fluctuation in the power transmitted. The discrepancies you mention (really the agreement is very close) are due to the fact that in French practice slightly different factors in formula are employed. You may rely upon that given in the Automotor Pocket-Book as embodying the latest and best practice in gas and oil engineering. As regards the diameter of shaft, the size is ample; such a shaft, if of good steel, could transmit at 700 revs. 14 H.P. We give an excellent rule for shafts on p. 94, and on p. 93 of the Pocket-Book we give formulæ for cranks and crank-shafts. For air cooling it is difficult to give the amount of surface, as so much depends upon the surrounding temperature and the general design. You will see a description of an air-condenser in the present issue.—Ed.]

THE DAIMLER MOTOR AND WHO SUPPLY IT.

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir,—On reading a letter on page 185 of this month's Automotor, relative to the price of Daimler Motors, we sent the enclosed letter, addressed to Edgar Wrightson, Esq., The Nine Elms, Hinckley, Birmingham, but it was returned from the Lost Letter Office marked "Not known at Hinckley." We should be very much obliged to you if you could forward the enclosed to the writer of the letter, or, if he cannot be found, if you would permit the enclosed to appear in your next issue.—We are, yours faithfully,

Per pro The Motor-Carriage Supply Co. (Ltd.),
E. E. Lefébure, Secretary.

Donington House, Norfolk Street, Strand, London, W.C.,
February 23rd, 1898.

[Enclosure.]

Dear Sir,—We notice your letter to the Editor of The Automotor and Horseless Vehicle Journal of January 5th, inquiring where you can obtain Daimler Motor-Carriages. We therefore beg to inform you that this Company is in a position to supply Daimler Motor-vehicles of the very best quality and workmanship, and ranging in H.P. from 4 to 20. These carriages are being manufactured by the most experienced men, under the personal supervision of Herr Daimler, the original inventor of the Daimler Motor, and the workmanship is of the most reliable kind. You will find there is no firm besides ourselves who can supply Daimler Motors of 4, 6, 8, and 10 H.P. If you will tell us what type of motor-vehicle you are seeking, we shall be pleased to send you full specification and quotation as to price. We may add that our carriages will contain many of the latest improvements which have not yet been adopted in the Daimler Motor-Carriages of this country, one of the most important improvements being an automatic form of electric ignition, which requires no accumulator and no recharging, and which is absolutely certain in action.—We are, yours faithfully,

Per pro The Motor-Carriage Supply Co. (Ltd.),
E. E. Lefébure, Secretary.

A DIFFICULT PROBLEM.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Messrs. Simpson and Bodman seem to have set themselves a somewhat difficult problem. They have come to the conclusion that a *short* wheel-base is necessary for steering purposes, and yet their vehicle must be sufficiently *long* to accommodate the engine, boiler, fuel and water necessary for propulsion, and at the same time leave as much room for cargo as in an ordinary horse-drawn "lorry." If you can bring yourself to adopt so grotesque a method as using more than four wheels, there is no difficulty at all; but then, of course, that idea is inadmissible—a six-wheeled van, for instance, would *look* so ridiculous. No engineer of repute would think of such a thing; he would rather bury his head in the sand like the ostrich, and say that he has decided that there *is* no automobile

industry after all! And perhaps he is right, too—until, that is, we can plan something better than merely *horseless* vehicles.—I am, &c.,
March 3rd, 1898. A. J. A.

[We are not sure that a six-wheeled vehicle is at all ridiculous, and we certainly do not believe in short wheel bases.—Ed.]

THE PYGMEE MOTOR.

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir, — Have just now subscribed to your Journal, through your agents, Messrs. Phillips and Ormond, Melbourne. Found a special notice in my first copy (November), with a list of contents and number of illustrations contained in each volume. However, I could not see anything of the Pygmee Motor for road carriages. Wallace Taylor states in his book, p. 147:—"The 'Pygmee' is one which, in point of efficiency, equals, if not surpasses, the Daimler Motor." Gives a very meagre account, and no illustrations showing the disposition of its parts, especially the regulating device. Would it be asking too much to give us a full account, together with illustrations of the same, in the Automotor Journal at an early date?—Yours very respectfully,

H. Austin.

Melbourne, *January 10th*, 1898.

[This is a French motor, and French makers are not at all inclined to give particulars of their machinery. We have endeavoured to obtain drawings, &c., but so far have not been successful.—Ed.]

THREE v. FOUR WHEELED CARS.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—It would be interesting to have some discussion as to the relative advantages of three and four wheeled motor-cars, up to a weight of 10 to 16 cwt. I am strongly in favour of three wheels. I find, however, considerable prejudice against this design. So far as my experience goes, the only disadvantage of the single front-steering wheel is in its being out of the usual wheel tracks; on very bad country roads this might have some little weight. On the other hand, the single steerer has distinct advantages, which I may tabulate as below:—

1. Simpler and cheaper construction of car.
2. Reduction of weight of car.
3. More certain and greater range of steering.
4. Less wind resistance.
5. Less road resistance.

These are all most important points in motor vehicles. In my experimental three-wheeled car I am able to run round in a circle of 5 feet 6 inches radius, being the length of wheel-base of car—that is to say, with steering wheel parallel to hind axle. This would be quite impossible with a four-wheeled car. I should, however, like to see the matter discussed in your useful columns.—Yours truly,

F. Lister.

Keighley, *March 5th*, 1898.

[We shall be glad to receive communications on this subject.—Ed.]

That Battery.—Says the *Chicago Herald*:—"The American Electric Vehicle Company, of Chicago, confirms the report that it is about to establish a factory at Dayton, O. C. E. Corrigan, manager of the Company, is at Dayton looking over the ground. Officers of the Company say they have so many advance orders they will start with 350 hands. Their horseless vehicles are operated by electric storage batteries, which have the merit of weighing only 13 lbs. as against the 40 lbs. of other systems. This battery is the invention of a Chicago man, and the Company is controlled by Chicago men, but Dayton people will be permitted to take $50,000 worth of stock." America is the country of great inventions truly. On this side if we can get a battery for an electrical cab weighing some 1,500 lbs. we think we are doing fairly well; but then we poor benighted Britishers cannot expect to keep pace with the American inventor and motor-vehicle maker. We long to see that battery which, according to the *Chicago Herald*, weighs but 13 lbs., or even 40 lbs. of "other systems." Really, we have much to learn.

PROCEEDINGS OF TECHNICAL SOCIETIES.

Mechanical Features of Electric Traction.*

(*Concluded.*)

Single-Reduction Motors.—The maturing of the design of single-reduction motors marks a distinct epoch in the construction of tramway motors. The practical experience of many years' use has proved them reliable and efficient; and they have fairly fulfilled the following essential requirements of a motor for tramways:—

1. The motor must be as light in weight as possible, having due regard to strength and simplicity in its mechanical and electrical construction.

2. It must be completely closed in, and protected from dirt, moisture, &c.

3. Its capacity must be ample, and it should be able to run continuously for at least two hours at its rated capacity, without heating beyond 90° to 135° F. It should be capable of developing at least 50 per cent. more than its rated capacity, without injurious sparking or other damage; and the starting torque must be great.

4. All the external and internal parts of the motor must be thoroughly accessible, and easily taken apart.

That motor is the best which enables the line to be worked at the lowest cost for fixed charges as well as for running expenses. The relation between weight of motor and expense of working is forcibly shown by the maintenance of way on various tramways at present working. A motor entirely protected from dirt, moisture, &c., needs far less repairs, and so diminishes the cost of working. If a motor does not keep within a certain limit of heating and sparking, renewals of parts will obviously become numerous and costly. Difficulty of access to the wearing parts means higher charges for maintenance and labour.

Gearing.—More than one reduction in gearing between armature and axle means too high speed of the armature, and consequently too great wear in the teeth. Any decrease in number of parts and bearings diminishes the cost of maintenance. Large teeth must be used, and the gearing must run in grease. Experience has proved the greater economy of steel over cast-iron gearing for tramway motors. A recent careful investigation of 66 tramways in 49 cities, using over 7,000 motors, has demonstrated that the average life of cast-iron gearing is somewhat over 30,000 miles, while that of steel gearing is nearly twice as great. Apart from the advantages of longer life and higher efficiency, there is much less danger of breakage in steel than in cast-iron gearing, and of consequent springing or breaking of shafts and frames. The teeth are cut out of a solid rim by finely made cutters of the best known shape, as determined by exhaustive experiments. Motor pinions should be made from the best hammered steel forgings, and the teeth should be formed by accurate cutters and specially designed machinery with the same care as is used in the manufacture of the gearing; and they should all undergo the same rigid inspection and tests as the gearing.

Power.—The average horse-power exerted by a tramway motor at the car wheel probably does not exceed 20 per cent. of the maximum power it is expected to exert in starting the car under the various conditions encountered. In order to get the best efficiency out of such a motor, it is necessary that its point of highest possible efficiency should coincide with the development of the power at which the greatest amount of work is to be done.

Suspension of Motors.—There are three principal ways in which the motors can be suspended from the trucks; they are known as "nose," and "side-bar," and "centre" suspension. In the first method, one end of the motor rests on the axle through its bearings, while the other is hung from the truck by a cross-bar and springs. An advantage claimed for this method is that the gearing wears more evenly. In "side-bar" suspension the weight is nearly all taken off the axles. A side frame resting entirely on springs carries the motor by two lugs, one on either side, which are so placed that the motor is suspended from its centre of gravity. This plan has not proved as successful as was anticipated; and the first, or "nose" suspension, is still much in use.

Rating of Motors.—This is rather a difficult question, because there are so many variable factors. At present nearly every manufacturer has a different method of rating, and a motor which

* Paper read at the Institution of Mechanical Engineers by Mr. Philip Dawson.

would be called 15 H.P. by one is called 30 H.P. by another. A tramway motor works intermittently, and, therefore, can exert for brief periods a much larger power than it could continuously. Motors may be rated either by the torque which when making a given number of revs. per minute they exert upon a wheel of a given diameter, that is to say, by their tractive effort; or else by the horse-power which they can develop. In both cases, however, care must be taken to state the length of time during which the motors are to exert their rated power; and also the rise of temperature permitted in that time. The General Electric Company, which is the largest manufacturing establishment in the United States, rates its motors by the torque which they can exert for one hour at the circumference either of a 30-inch or of a 33-inch wheel, at the speed for which they have been constructed, with a limiting rise in temperature of 135° F. after a run of one hour. Such a rating fairly represents the maximum conditions of ordinary working, and leaves sufficient margin to meet emergencies without injury to the motor. Instead of expressing the power of the motor by the torque, the tractive effort which the motor can give out at the normal speed may be stated. Motors may also be rated by the horse-power which they can safely give out temporarily, while they are so designed that they can run continuously at half that rated power without their temperature rising by more than 90° to 135° F. Inasmuch as all the insulation used in the construction of tramway motors is practically fireproof, they can stand a far greater amount of heating than ordinary stationary motors. It is unnecessary to go into the electrical details of the devices used for controlling the speed with tramway motors; they can now be considered practically perfect, and they are so designed mechanically that it is impossible for an attendant to make a mistake in handling them.

Power Station.—The success or failure of an electric line depends to no small extent upon the situation and design of the power station. The conditions which govern its erection are in many ways entirely different from those which have to be considered in the construction of an electric-lighting station. The load is constantly varying, and the variations are large and unexpected. Breakdowns are more serious than in electric lighting; and such precautions must be taken as will render a suspension of service practically impossible under any circumstances. In many instances the station must be in continuous operation for several consecutive days. In large American power stations certain of the engines have frequently been running for eight and ten days continuously. In Table 9 are given the sizes of engines recommended for use in power stations.

TABLE 9.—*Sizes of Engines recommended for use in Power Stations.*

Maximum Power required. I.H.P.	Number of Engines.	Power of each Engine. I.H.P.
200	2	200
400	3	200
600	3	300
1,000	3	500
1,500	4	500
2,000	4	750
5,000	6	1,000
10,000	6	2,000

In early days the engines employed were far too small and weak. At the present time dynamos for tramway work are so constructed that accidents to them are quite as rare as to the driving engines themselves. Countershafts have been abandoned as wasteful in power and useless. Large reserves of power were also provided on the earlier electric lines; this practice has been abandoned, and Table 9 shows the reserve power which should be allowed; it will be seen that a sufficient number of engines are provided to furnish the maximum horse-power required for working the line, with a surplus of one engine in reserve. With this reserve the machinery can be kept in perfect adjustment and repair, one engine being at all times stationary. In case of a breakdown, this extra engine is ready to take the place of the one disabled.

Driving.—A great diversity of opinion used to exist as to whether the engines should drive the generators by belts or ropes, or be directly coupled. The great objection advanced against direct coupling was the want of elasticity, which in the event of sudden and heavy overloading might cause a breakdown of the engine itself. It is said that belts and ropes act as a spring, and prevent sudden shocks from damaging the engine. It seems, however, to be beyond doubt that, for large stations having direct-coupled engines of 500 H.P. and upwards, slow-speed compound condensing engines, horizontal or vertical, are preferable. Direct coupling is steadily gaining ground, and should always be used for units of 100 kilowatts and upwards.

Stations should always be built as compact as possible; but space, light, and, above all, ventilation, should never be grudged in the engine room. Whether vertical or horizontal engines are adopted seems to depend primarily upon the available space; and secondly, and to a large degree, upon the fancy of the designing engineer.

Power.—Tramway work being of such a character that even in the largest stations the average load rarely exceeds two-thirds of the maximum, it becomes necessary, in order to have an economical engine, for it to be so constructed that at its most economical cut-off it will give out two-thirds of its maximum power. Thus, supposing an engine at its most economical cut off of 28 per cent. will give 350 H.P., at its maximum cut-off of 80 per cent. it will give 520 H.P. When, therefore, an engine of 350 H.P. is ordered, it is expected to be able to run at 50 per cent. overload, the generators being constructed to stand the same strain. All bearings must be of such ample dimensions as to run perfectly cool when the engine is working at 50 per cent. above its rated power.

Engines.—In consequence of the difference of conditions between a lighting and a traction station, all engine builders who have had experience in tramway work now build an entirely different kind of engine for traction from that which they supply for lighting stations, as far as dimensions and weights are concerned, as indicated in Table 10. The conditions under which a tramway engine works are if anything more onerous than those of a rolling-mill engine. A slight variation either in number of revolutions per minute or in angular velocity per revolution is of the greatest importance in a traction station, whereas it is of small importance in a rolling mill. A traction station should always be so arranged that, if the normal load be suddenly thrown on or off an engine, the speed shall not vary more than 2 per cent. In some cases a maximum variation of 1¼ and 1½ per cent. is all that is allowed. Where polyphase currents are used, constant speed is of even greater importance; and a guarantee should be required that under no circumstances shall the angular velocity during one revolution vary more than three-quarters of 1 per cent., and in some cases not more than half of 1 per cent. With heavy fly-wheels, and governors properly designed for tramway work, especially when the governors are of the fly-wheel kind, it is quite practicable to fulfil the above conditions. A shaft governor is undoubtedly far more satisfactory in every way than any ball governor driven by belt or gearing from the engine shaft.

TABLE 10.—*Comparative Weights of Engines for Lighting and for Traction.*

Power of Engine.	Weight of Engine. For Lighting.	For Traction.	Difference.
I.H.P.	lbs. tons.	lbs. tons.	lbs. tons.
90	13,000 = 5·8	15,000 = 6·7	2,000 = 0·9
115	15,000 = 6·7	17,000 = 7·6	2,000 = 0·9
140	21,000 = 9·4	23,500 = 10·5	2,500 = 1·1
215	33,000 = 14·8	37,000 = 16·6	4,000 = 1·8
325	46,000 = 20·5	50,000 = 22·3	4,000 = 1·8
400	53,000 = 23·7	58,000 = 25·9	5,000 = 2·2
500	74,000 = 33·0	80,000 = 35·7	6,000 = 2·7

Governing.—During the last few years there have been several fly-wheel accidents in tramway stations in America. Respecting these accidents and fly-wheels in general, more is said later on. Most fly-wheel accidents have occurred with engines employing a releasing valve gear and a delicate ball governor. When the load is suddenly thrown off, and when they have to work with no load and a vacuum, ball governors are too uncertain. They generally act; but occasionally the valve gear, owing to wear or bad adjustment, prevents the engine from controlling itself. To obviate this, a second governor is put in engines of this class, which governs some 10 revolutions slower than the main governor, and which, when it exceeds the speed it is set for, causes a stop-valve to trip, whereby the steam is entirely shut off from the engine. This seems to be an admission that such engines are liable to run away. With powerful shaft governors connected directly to the cut-off valves hy means of positive mechanism it is impossible for engines to run away.

Tahle 11 gives the standard dimensions of bearings and fly-wheels and the weights of typical engines now successfully working large tramway stations. Tho first two examples are engines with fly-wheel governors; the smaller engines are fitted with single or double piston valves, and the larger with gridiron valves. In small engines tbe governor acts only on the high-pressure cylinder, hut in large engines it is so arranged as to act on both cylinders. Table 12 gives tbe dimensions of some standard Continental engines, most of which are driving rolling mills. On comparing the dimensions of the bearings in this tahle with those of the tramway engines, it will be seen that the ratio of the length of the bearing to its diameter in the tramway engines is generally somewhere near 2 to 1 (Tahle 11), whereas in the engines not designed for tramway work it is nearer 1¼ to 1 (Table 12). The main bearings are usually provided with cylindrical shells, which can be taken out by simply jacking up the shaft to take the weight off tbe bearings. The shells are made hollow for water circulation, which can be used in case the bearings should heat from dirt or other cause; by this means the engine can he enabled to complete its run.

TABLE 13.—*Tests of Pratt Street Electric-Power Station, City and Suburban Railway, Baltimore.*

—	Date of Test, 1695.				
	August 14.	August 16.	August 17.	August 21.	Average.
Average I.H.P. for 20 hours ...	1,860	1,873	1,773	2,000	1,876·5
„ E.H.P. „ „ ...	1,395·5	1,405	1,330	1,499	1,407·4
Coal used, total ... ... lbs.	75,678	70,885	72,835	74,511	73,490
„ per I.H.P. per hour, engines only lb.	1·83	1·70	1·85	1·67	1·76
„ per I.H.P. per hour, other machinery lb.	0·20	0·19	0·21	0·19	0·20
„ per I.H.P. per hour, entire station lbs.	2·03	1·69	2·06	1·86	1·96
„ per E.H.P. per hour, entire station lbs.	2·71	2·52	2·74	2·48	2·61

COAL CONSUMPTION.—The above consumptions are based on the total amount of coal actually used in the station for the above electric output, no deductions being made for ash, clinker, or moisture.

LOAD.—The heaviest load was 781 I.H.P., the lightest 366, and the average during four hours 553 I.H.P.

GENERATORS.—Four 500 kilowatt by General Electric Company, of 670 E.H.P. each, making 2,680 E.H.P.; and one 200 kilowatt, of 268 E.H.P.; total, 2,948 E.H.P.

BOILERS.—Campbell and Zell water-tube, four sets of 700 H.P., making 2,800 H.P. total.

ENGINES.—Four compound by McIntosh and Seymour, cylinders 20 and 36 inches diameter by 36 inches stroke, of 750 economical I.H.P. each, making 3,000 I.H.P.; one compound by same makers, cylinders 15 and 23 inches diameter by 17 inches stroke, of 250 economical I.H.P.; stoker, hoisting and conveying engines of 50 I.H.P.; total, 3,300 I.H.P.

Two Blake vertical twin air-pumps and condensers, each 1,800 H.P. capacity, making 3,600 H.P.; one horizontal ditto, 250 H.P.; total, 3,850 H.P. capacity.

Two Blake duplex feed-pumps, 14 and 8½ inches diameter by 12 inches stroke, each 2,800 H.P. capacity, making 5,600 H.P.; two combined pumps and receivers, 6 and 4½ inches diameter by 7 inches stroke, each 4,500 H.P capacity, making 9,000 H.P.; total, 14,600 H.P.

Hunt's coal and ash conveying apparatus. Roney mechanical stokers.

Tests.—Table 13 gives the results of tests recently made in a largo American station. There are four tandem compound condensing engines—bigh-pressure cylinder, 20 inches diameter; low-pressure, 36 inches; stroke, 36 inches; initial pressure, 125 lbs. per square inch; economical cut off, $\frac{5}{18}$ of stroke in high-pressure cylinder; vacuum, 24 inches of mercury; revolutions, 103 per minute. These four engines each drive by belt a 500 kilowatt generator; and there is one direct-coupled engine, with cylinders 15 and 23 inches diameter, and 17 inches stroke, driving a 200 kilowatt generator. The results may he considered highly satisfactory. Practically the minimum coal consumption is 1·67 lbs. per I.H.P., and 2·48 lbs. per E.H.P. at the switchboard. It therefore appears safe in a well-designed and fairly large station to estimate the coal consumption per I.H.P. at 2 lbs., and per E.H.P. at not more than 2·66 lbs., so that the coal consumption per Board of Trade unit will not exceed 3·3 lbs.

Fly-wheels.—The use of fly-wbeels in electric traction stations is important. Owing to the need of keeping the angular velocity as constant as possible, especially in large stations where, owing to Board of Trade regulations, polyphase transmissions become a necessity, the fly-wheels have to be much heavier tban for ordinary lighting work. The strains they may be called upon to bear occasionally are enormous. The dynamos for tramway work are now constructed with such an amount of copper, and with such fire-proof insulation, that they can stand short-circuiting without serious damage. Circuit-breakers are, of course, supplied, and are generally prompt in action; hut it may happen, and has occasionally occurred, that something goes wrong witb the circuit-breaker, and it will not immediately break the line when a sbort circuit occurs. It may therefore happen that an engine may be practically stopped dead, and enormous strains may thus be put on the fly-wbeel. Moreover, the moment the fly-wheel has stopped, the circuit-breaker may happen to act, and the full power behind the piston may be applied to rotate the wheel, thereby again subjecting it to great strains. The utmost care has therefore to be taken in the design of fly-wheels. Accidents cause terrific havoc, and as far as the damage done is concerned are nearly as bad as boiler explosions, if not worse. In America the circumferential speeds allowed, even with cast-iron wheels, are much in excess of those to be met with in this country or on the Continent; over 90 feet per second is frequently allowed, as seen from some of the tables, whereas in English practice it is not considered safe to go beyond 80 feet. This may possibly be owing to the better quality of cast-iron in America.

Fly-wheels built up of rolled plates, and constructed more like a boiler or a bridge, have been adopted to some extent in electric tramway stations in America. These built-up wbeels generally have a cast-iron centre or hub, with brackets to which tbo armature is bolted, so as to take some of the strain off the two keys that hold the armature on the sbaft. To the centre of the hub are connected segmental web-plates, extending to the extreme outside diameter of tbe wheel. The plates are faced along their edges, so as to form a good joint. Outside of these segments are two circular plates, bolted through each segment and through both plate and hub. The segments are generally braced by truss pieces, held in the centre by cross bolts which act as struts. Outside tbe web plates surrounding the rim is a strip riveted through the rim; and outside of this is a second strip also riveted through. The rims of these wheels are usually turned down after the wheels have heen riveted up and fixed on the shaft.

Accidents to fly-wheels may generally be attributed to three chief causes:—Firstly, poor castings or internal strains; secondly, faulty design and construction; thirdly, excessive speed. In designing a fly-wheel it is easy to calculate its parts so that it shall be perfectly safe to bring it to a standstill within a given angle. Investigation of some of the best fly-wheels for tramway stations shows that their design permits of their being stopped in less than one revolution, with factors of safety varying from 17 to 18.

Generators.—The kind of generator to be used for electric traction is an important question. As in the case of the engines, tramway generators (Table 14) must stand heavy overloading without damage. Moreover, as one pole is earthed, the greatest care must be taken that the best insulation is used throughout. Since the loads to which they are subject are extremely variable, dynamos as usually constructed for lighting work would require the position of their brushes to be constantly altered. To obviate this, heavy magnetic inductions are allowed for in designing tramway generators, thus rendering it unnecessary to shift the brushes, and also avoiding sparking. It is the universal and best practice to use toothed armatures in tramway work.

TABLE 14.—*Electric Tramway Generators.*

Rated Power.	Total Weight of Generator.	Diameter of Shaft.	Armature. Diameter.	Armature. Weight.	Number of Poles.	Revolutions per Minute.	Commercial Efficiency. Full load.	Commercial Efficiency. Half load.	Commercial Efficiency. Quarter load.

	64,300 = 28·8	15 to 18	72	28,740 = 12·8	8	120			
	59,700 = 26·6	14 to 16	65½	24,900 = 11·1	6	150			
500	87,100 = 38·9	16 to 18	88½	35,800 = 16·0	10	75	94	93	89½
	76,000 = 34·0	16 to 18	88½	32,000 = 14·1	10	90			
	71,300 = 31·8	16 to 18	88½	30,500 = 13·6	10	100			
	64,300 = 28·8	16 to 18	88½	27,100 = 12·1	10	125			
800	110,000 = 49·1	19 to 22	94½	49,440 = 22·1	10	80	94½	93½	90
	100,900 = 45·0	19 to 22	94½	45,520 = 20·3	10	100			
	94,400 = 42·2	19 to 22	94½	41,170 = 18·4	10	120			
1,300	158,930 = 71·0	21 to 27	126	69,910 = 31·2	12	80	95	94	90½
1,500	163,200 = 72·5	24 to 27	126	73,100 = 32·6	12	75	95	94	90½
250	40,000 = 17·8	12 to 14	60	15,000 = 6·7		100			
400	60,000 = 26·8	16 to 19	75	25,000 = 11·2		90 to 100			
500	90,000 = 40·0	18 to 21	80	30,000 = 13·4		90			
800	125,000 = 55·8	21 to 23	90	40,000 = 17·8		80 to 90			
1,200	195,000 = 87·1	23 to 25	115	65,000 = 29·0		80			
1,500	240,000 = 107·0	24 to 27	130	70,000 = 31·3		75			

As to the kind of field winding which should be adopted, it would seem from tests made on a large scale with separately excited shunt-wound, and compound-wound machines, that the best suited to tramway work from every point of view is the over-compounded generator. The usual pressure of current employed on trolley lines is 500 volts; and for this tension dynamos are so designed that the pressure between their terminals is 500 volts at no load, and is increased to 550 volts when the full load comes on. The over-compounding can be regulated up to 10 per cent. by varying a German-silver shunt placed on the series coil.

Automobilism on Roads.*

(*Continued from p.* 196.)

Some evidence of this is given by an examination of a London granite macadam road when it is broken up for any purpose. Down to a depth of several inches it will be found that the once sharply angular stones have all been more or less rounded by the rubbing together of the adjacent pieces before they became fixed by the crumbled and pressed material from the corners of every other surrounding piece. This process commences with the steam-rolling of the large stuff tipped and levelled with the shovel. If the progress of a heavy roller be watched, a wave of the road material immediately in front of the rollers will be seen, a wave which gradually lessens as the rolling approaches completion, but which is there to the end, and is formed in both backward and forward travel. In this way not only does the road-metal get its corners rubbed off, but there is more or less regular recurrence of harder and softer places formed by the recurrent surmounting of the wave. The really good road surface cannot be made in this way, and an illustration of the reason may be given by a reference to what would happen if a similar process were adopted with a heap of loaf sugar. If a large box of broken loaf sugar were put under a heavy roller to make a level hard surface, an irregular hard and soft surface would be obtained, with a sub-surface of crushed lumps. If, however, every piece were carefully packed, a very little or no rolling would be necessary. Now, although packing by hand, like laying of small bricks, cannot perhaps be indulged in in macadam road-making, the packing should be done, and I believe can be done by apparatus not at all difficult to devise.

Of the third very desirable improvement in our roads it is impossible in this address to do more than call attention to the vast saving that might be made in work done and wasted, in time lost, and in avoidable accidents, by the profitable employment of capital in reducing the hill gradients, and in making up the roads across hollows.

As an example of this class of work reference may be made to the proposed new road through the Sty Head Pass from Borrowdale to Wasdale. Here a new road is to be made according to the plans of Mr. G. J. Bell, which will reduce the gradient of 5¼ to 1 of the pony road hitherto used to 1 in 20 one side of the summit, and 1 in 12 the most on the other; that is to say, the power of every pony or horse will be more than treble, as between Wast Water and the Sty Head, and more than doubled on the Borrowdale side. In this case a certain summit 1,578·6 feet above datum has to be reached from starting point at 264 feet, and the length of the road has to be increased from 4·3 to 7·88 miles, but the time taken with the doubled or trebled load will only be about the same. The road is to be 18 feet wide, and the whole cost will be only £10,000, or about £1,260 per mile. This is an extreme case, a rise of over 1,300 feet being made under five miles. In many cases, however, the road improvement will be made by taking the top off the hill, going through it or round it, not necessarily surmounting it, and while the gradient will not often be improved by so large a reduction, the length of the road will, on the other hand, not be increased.

The capital expenditure on the Sty Head road will only represent a yearly charge of, say, £350, and for this a good safe road is obtained, the transporting power of every horse is doubled, and safety is exchanged for many dangers. Either less than half the horses will be necessary, or more than double the passengers or baggage can be carried. Assume that four one-horse journeys each way are made per day for six months of the year, we have, for only six days per week, 1,296 journeys. To this addition to the horse's journeys or to his load must be added the numerous profits arising from the doubled power of transport, and when these are put together it will be obvious that the inhabitants will reap a handsome return for the money expended.

This is only a small example of the kind of work which could be carried out in many main and secondary roads all over the country. Many of the Kent hill roads, for example, might, with the greatest advantage to the ratepayers, be put into the hands of the engineers, as in days gone by the roads of the north were put into those of Telford. Small detours and small cuttings and banks, which in these days can be carried out by mechanical means at small cost, would in many cases cheat gravity of half of its natural aid to high rates for cartage. The hills of the 100,000 miles of road in this country not only cost us an enormous sum every year to surmount, but they put the most effective stop on the cheapening of road transit of goods between railway stations, villages, and agricultural districts.

The days are past when the natural highways were looked upon as only of importance to those who used them. Everything that can be done to make haulage on the roads easier and cheaper, cheapens commodities partly by the reduced number of horses necessary or by the use of mechanical road vehicles, and partly by saving of time, which is equally valuable. We have arrived now at a time when it is seen that the great railway system which has

* Excerpt from the inaugural address delivered by Mr. WORBY BEAUMONT, M.I.C.E., M.I.M.E., &c., before the Society of Engineers, London, on February 7th.

done so much for us has its limits with regard to distribution, and we see now the common high road must again receive the attention which for some years was given to it in the early part of this century under Telford and others. The extensive employment of engineers must again be resorted to for the planning of new and the improvement of existing roads, and the mechanical aid to road transport, which was spurned when railways were growing up everywhere and promising everything, must now be taken into service.

If we are to have the advantages of cheap and rapid transit between the hard and fast points of railway service we must have mechanical power on the roads. Already the importance of this is recognised, but it is necessary to point out that to secure the great possible advantages of this we must have not only the mechanically propelled vehicles and the roads suitable for their working, but that these very road improvements are as desirable for the horse-propelled vehicles.

Over many miles of suburban and country roads the construction of really well-made macadam roads, with wheel ways at the sides, will make a splendid national investment. The better the road the longer it lasts, the less the time lost by stoppages of traffic for heavy repairs, the greater the average speed of travelling of goods and passengers.

The haulage resistance on well-finished macadam roads is less than half that on a badly-made road of the same kind. This means more than the old fact that one horse would do the work now done by two, and do it quicker. With the improvement of the worst gradient, one horse could in many parts do the work now done by three, for it happens frequently that the full power of the two or three horses of a team is only required for a fraction of the whole road traversed. Further than this, it means that the mechanically-propelled vehicle could do with either less than half the steam-engine power now necessary, or could carry much greater loads, and the average speed would be greatly increased without making any addition to the full speed. In fact the maximum speed could be reduced, and a higher average speed attained.

With the improved roads the cost of fuel either as horse feed or as coal or oil, would be enormously reduced, especially in the case of horses, and the distance traversed by mechanical road vehicles with one supply of fuel and water would be proportionally increased. The reduction of cost in this respect is comparable with that of locomotives on the railways as against that by horses, but not equal to it in every respect.

When stage and mail coaches were employed the allowance of horses was a horse per mile of double coach road. Now see what this means on the London and Birmingham road. The distance is 113 miles, which would require 56 horses per coach for the single journey. These horses would consume about 28 lbs. of food per day each, so that for the journey from London to Birmingham 14 cwt. of food would be consumed in order to convey at most 14 passengers, or 1 cwt. per passenger. This food at the present day would cost not less than 5*s*., so that the cost for food fuel alone for, say, the 500 passengers (which a locomotive of to-day would take) would be £125, and it would weigh 25 tons. The locomotive takes the 500 passengers for about 1·8 tons of coal, or about 8 lbs. per passenger instead of 112 lbs. The coach carried a passenger for about 35*s*. of the then value, and the engine does it for 9*s*. 5*d*. present value.

To take the 500 passengers to-day it would have required 35 or 36 coaches and 2,000 horses, and they would do the journey in 11 hours, while a 700-horse engine does the distance in 2¼ hours. Thus the passenger does the journey in less than quarter the time and quarter the cost, and for a visit for a few hours he saves the cost of staying a night at an hotel, saves the cost of about nine hours' travelling refreshments, and saves the value of at least a day of his time. Thus one train carrying 500 passengers saves over a year and a half of working days.

For each 20 travellers a ton of food had to be carted for the horses, while at the present time each passenger could carry the necessary coal in his pocket to take him the journey. The time saved is one of the greatest of all, and, although we do not always remember this, it is one of the several ways in which the steam-engine has more than doubled the money-earning capacity of men who do much travelling, and has increased the earning power of all.

(*To be concluded.*)

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Specifications Published.

THE following is a List of Specifications recently published, and obtainable at the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform charge of 8*d*. per copy. Owing to the enormous pressure upon our columns it has been found impossible to deal in any other form with the accumulation of patents now being taken out in connection with automobilism. As far as possible, a selection for special mention is made by the Editor from the more prominent inventions:—

Applied for during 1896.

27,368. R. WADSWORTH, Sanitary Implement Works, Thomas Street, Halifax, Yorks. Motor road-sweeping, watering, &c., vans.

27,603. Major H. C. L. HOLDEN, Royal Arsenal, Woolwich. Construction of internal combustion engines in combination with cycles or carriages.

28,833. J. RIDGE, T. MUTTON, and H. E. HUPTON, 84½, Kings Road, Brighton. Gearing.

28,850. H. LANE, Corporation Street, Birmingham. Method of and apparatus for applying motive power to vehicles running on ordinary roads.

29,269. F. J. GIBBS and W. WRIGHT, 70, Lower Hurst Street, Birmingham. Pneumatic tyres.

28,585. MILLS. Hubs for wheels.

30,145. E. ARCHDEACON, 12, Rue du Ranelagh, Paris. Driving gear.

28,192. H. R. GILLING, Oaklands, Arkley, Barnet, Herts. Pneumatic spring arrangements.

28,400. THOMPSON (J. Dulait), Charleroi, Belgium. Electrically-propelled motor road-vehicles.

28,422. W. T. SHAW, L. W. BOOTHROYD, and A. SYDENHAM, 29, Clerkenwell Road, London. Driving gear.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

VOL. II. No. 19. APRIL 16TH, 1898. PRICE SIXPENCE.

CONTENTS.

MOTOR DUST-CARTS FOR CHELSEA.

THE Chelsea Vestry lately instructed their surveyor, Mr. T. W. Higgins, Assoc. M.I.C.E., to report upon the advisability of utilising motor vehicles for the collection of house and street refuse. This gentleman has reported at considerable length upon the subject. After some elementary remarks upon automobilism and means of obtaining the motive power, he says:—

In order to obtain the necessary estimates I wrote to 11 firms asking if they were prepared to submit estimates to the Vestry for motor dust-vans. These vans I specified were each to contain 6 cubic yards of refuse which would not weigh more than 4 tons, they were to be worked in accordance with the Locomotives on Highways Act of 1896; and would be required to tip the refuse over a shoot.

From the replies I received it seems evident that a vehicle of the size I specified is rather beyond the capacity of the ordinary electric-motor or oil-engine.

There do not at present seem to be any firms making electrically-driven cars of the size we require. The makers of electric motor-cars seem to be directing their attention more to light passenger vehicles than to heavy vans for business purposes.

The Daimler Motor Company and the Great Horseless Carriage Company, of Coventry, both makers of oil-motors, write that at present they are unable to quote for so large and heavy a type of car as would be required for the purpose we have in view.

Messrs. Roots and Venables, of Westminster Bridge Road, will build a dust-van driven by an oil-motor of 6 H.P. geared to run at any speed not exceeding 6 miles an hour, and capable of carrying a load of 1½ tons, for £375. The engine would be driven by ordinary paraffin, and the cost of fuel would be less than 3*d*. per hour. This van is, I think, too light for the work required. If a van of larger capacity is used the time spent in travelling backwards and forwards to the wharf to tip will be reduced by one half.

Five firms have submitted estimates and specifications for steam motor-vans, viz.:—

(1) The Lancashire Steam Motor Company, of Leyland.
(2) Messrs. T. Coulthard and Co., of Preston.
(3) Messrs. Toward and Co., of Newcastle-on-Tyne.
(4) The Liquid Fuel Engineering Company, of East Cowes.
(5) The Steam Carriage and Wagon Company, of Chiswick.

The prices of their motor-vans and the description of machinery to be used are as follows:—

(1) The Lancashire Steam Motor Company, of Leyland, will build a steam motor dust-van for £320. The tip van to carry 6 cubic yards of dust, the weight of dust not to exceed 4 tons. The body of the van to be made of ash supported with ironwork. The underframe to be channel steel filled up with oak. The engine and boiler to be placed alongside the driver's seat within a covered shelter for the driver. The engine to be a compound steam-engine of about 14½ H.P., to give a speed of 4 miles an hour; and the boiler to be composed of patent copper conical tubes, and to work at 200 lbs. to the square inch.

The firing is done by a patent automatic oil-firing apparatus which keeps the working pressure steady; it is quite independent of the driver's attention after he has once lighted the burner. The consumption of oil does not exceed two gallons per hour when in full work. The commonest paraffin oil is used.

The Lancashire Steam Motor Company are the makers of steam road vehicles and lawn mowers.

(2) Messrs. T. Coulthard and Co., of Preston, will build a steam motor dust-van for £340; if the 12 vans are ordered at the same time there will be a reduction of 5 per cent. The tip van is to carry 6 cubic yards of dust, the weight of dust not to exceed 4 tons.

The effective H.P. of the engine is to be under ordinary conditions 9 H.P., but when high pressure steam is used in both cylinders

18 H.P. A patent distribution valve will be used which will admit of the steam being regulated between "no load" and "full load," the whole operation being performed with one lever. The engine is fully protected from dust and can easily be cleaned. The boiler is of the water-tube type, oil fired, all the tubes are straight and accessible.

The tip van is to be built by the Gloucester Carriage Company, and is to be provided with their patent tipping gear.

The engine and boiler will be placed alongside the driver's seat, and the driver will be protected by a covered shelter. The consumption of oil—ordinary lamp oil—will be less than 15 gallons during the day's work.

Messrs. Coulthard and Co. have a van in use at Preston which is used for carrying coal and heavy goods.

(3) Messrs. Toward and Co., of Newcastle-on-Tyne, will build one steam motor dust-van for £430. The engine and boiler would be placed under and alongside the driver's seat within a covered shelter. The engine would be a compound steam-engine, fired with coal or coke, having an intermediate shaft geared for 5 and 3 miles per hour. The road wheels would be of steel with iron tyres.

The tip van is to contain about 6 cubic yards, the weight of dust not to exceed 4 tons.

The approximate cost of working, according to the makers, would probably be:—

Driver	20s. to 25s.	per week.
Coke or coal	5s. to 6s.	,,
Waste stores	3s. to 4s.	,,
Total	28s. to 35s.	,,

Messrs. Toward and Co. have built a steam-driven parcels van, which is now in use in the North.

(4) The Liquid Fuel Engineering Company, East Cowes, Isle of Wight, will build a steam motor dust-van for £525, but if the order is given for three vans at the same time the price to be £475. The tip van is to carry 6 yards of dust or from 3 to 5 tons of rubbish. It is to be built of suitable seasoned wood, the frames to be of best channel iron. The engine and boiler to be placed in front of the van. The engine to be a compound steam-engine, and the vehicle is to have a speed of from 5 to 6 miles an hour, the boiler to be of the water-tube pattern, ordinary paraffin oil to be burnt, and the firing is automatically regulated by means of the steam pressure in the boiler. The van is fitted with a steam ejector, whereby dust-bins could be steamed out.

The Liquid Fuel Engineering Company are the makers of the steam motor road train which runs between Circencester and Fairford.

(5) The Steam Carriage and Wagon Company (Limited), of Chiswick, will build a steam motor dust-van for £668. The tip van is to contain 6 cubic yards of dust, and will carry a load of 3 tons up an incline of 1 in 20 on ordinary macadam roads.

The main framing is to be of steel, as also are the wheels. The engine and boiler will be placed alongside the driver's seat and will be protected by a covered shelter. The boiler will be of the Thornycroft water-tube type, with special arrangements for the control of steam and silent blowing safety-valve; the engine, a compound reversing one, being enclosed in a dust-proof and oil-tight casing.

The Steam Carriage and Wagon Company are the makers of the two motor dust-vans now in use at Chiswick, which collect an average of 20 cubic yards of refuse per day with a consumption of 2 cwt. of steam coal.

The prices of these vehicles vary considerably, and an inspection of the plans and specifications submitted does not show sufficient reason for such a difference, but the two lowest estimates are very close. A sum of £320 or £340 is not much to pay for a motor-van of this capacity, and if a thoroughly reliable motor can be obtained at that price I think the Vestry would be wise in purchasing one on the understanding that if it worked to their satisfaction for six months they would obtain more motor-vans from the same maker.

The Vestry's resolution suggested 12 for the home district and three for Kensal Town, but I consider that at present 10 for the Home District and two for Kensal Town would be all that would be required, as each motor-van would do the work of two ordinary dust-carts, probably more, but how much more could only be ascertained by actual trial of a motor-van.

The cost of a motor-van compared with two dust carts and horses would be:—

Motor Van.

	£	s.	d.
Capital expenditure	320	0	0
Annual expenditure—			
Driver's wages, 35s. per week	1	15	0
Two dustmen, 25s. ditto	2	10	0
Fuel, water, &c.	2	0	0
Per week	£6	5	0
£6 5s. for 52 weeks = per annum	325	0	0
10 per cent. for depreciation, &c., say ..	32	10	0
	£357	10	0

Two Dust-Vans and Horses.

	£	s.	d.
Capital expenditure—			
Two horses at £70	140	0	0
Two dust-vans at £50	100	0	0
	£240	0	0
Annual expenditure—			
Driver's wages, two at 28s. per week ..	2	16	0
Two dustmen at 25s. ditto	2	10	0
Fodder, &c., two horses at 16s. per week ..	1	12	0
Per week	£6	18	0
£6 18s. for 52 weeks = per annum	358	16	0
Depreciation at 5 per cent.	12	0	0
	£370	16	0

The above shows that though the capital expenditure would be about £80 more for a motor-van than two horse-driven ones, yet the annual expenditure on the former is sufficiently low to more than repay the interest on the extra money borrowed to pay capital expenditure on the motor-van.

The annual expenditure on the motor-van would probably be about £12 or £13 less than for the horse-driven dust-vans, and if 12 were obtained the saving would be about £150, that is if each motor only did the work of two dust-vans. I think, however, it would do more. Besides, there is always the risk of a valuable horse dying. In looking through the annual report of an adjoining parish I find that out of a stud of 112 horses, six died or were killed during the year. One worth £80 only worked one month, another worth £74 three months, the others worked 3, 4, 4½, and 6 years respectively. An engine can be repaired and its interior renewed; a horse, however, goes to the knackers or the zoological gardens to feed the lions when any portion of his vital machinery goes wrong.

In conclusion, I consider that the offer of the Lancashire Steam Motor Company for a motor dust-van to cost £320, and that of Messrs. Coulthard and Co. to cost £340, deserve the careful consideration of the Vestry, but I cannot go so far as to actually recommend either of the two firms until I have seen their vehicles at work so as to satisfy myself that their arrangements for burning liquid fuel are quite satisfactory.

[The above report is useful and instructive as far as it goes. Mr. Higgins does not, however, adequately demonstrate the superior economy of the motor-vehicle. By the aid of Kelvin's "Law of Economy,"* we can determine this very exactly on the assumption that one motor dust-cart can replace two horse-propelled carts, and that the figures given above are accurate. This law tells us that "*the most economical design in any case is that in which the annual interest on the cost of an increment of material is equal to the saving in annual expenses which results from that increment.*" We then have:—

Two horse-propelled carts, cost	£240
One motor-cart, cost	320
Increment of capital	£80
Interest on, at 5 per cent. per annum	£4

* *Vide* Automotor and Horseless Vehicle Journal, Vol. II, October, 1897.

Annual cost of working two horse-propelled carts	£371
Annual cost of working one motor	357·5
Saving in annual expenses by employing motor-cart	£13·5

Inasmuch then as £13·5 is greater than £4 the economy is also very great, but assuming again that the motor-cart has a larger capacity, *i.e.*, it can perform more work in a given time than two ordinary horse-propelled carts, the economical advantage is still greater.—Ed.]

THE OPPERMANN VICTORIA.

Electric traction for vehicles plying in city and suburban districts has at length emerged from the region of experiment, and is now a mere commercial matter. Just as any one who can obtain a police license can become a hackney cab proprietor, so any one with the necessary capital can become an electric cab proprietor, with just the same commercial risk. Nearly every town of importance possesses an electric lighting station, or other sources of electrical energy, and arrangements for charging can in most cases be made with the same facility as the purchase of hay and fodder. Or, preferably, the enterprising electric cab proprietor can put down his own plant, and so reduce the cost of charging his cells. Among others who have rendered this agreeable elimination of the horse possible, the public have to thank Mr. Carl Oppermann, of Clerkenwell, London. This gentleman took up the question of electric traction by secondary batteries some years ago, and, like his colleagues who worked at the same problem, he had many difficulties to overcome. From the theoretical point of view the system of traction is charmingly simple. All you have to do, says the man in the street, is to pour electricity into a battery, which doles it out to the motor, which turns the wheels, and there you are! As many of our readers know, the solution of the problem of propelling a cab by electricity derived from storage cells was only a little less difficult than that of designing a successful arc lamp, or that of conveying high tension currents. And this problem required much time, thought, labour, and money, to solve. Of the nature of the difficulties that have been overcome we need say but little more than that improvement in some details is yet wanted, but in the main the problem is, as we say, practically solved. Mr. Carl Oppermann, unlike some other constructors, has managed to satisfy the æsthetic sense, as will be seen from the accompanying illustration. His latest vehicle, a Victoria, is distinctly handsome, and strikes one as being natural and elegant in its design. There is nothing of the ambulance wagon about it. It is essentially a vehicle that a gentleman would instinctively select for social purposes.

The battery is contained in a box attached to the body of the vehicle, and 40 "Headland" cells arranged in four groups of 10 each. The whole can be arranged either in parallel or series, or two groups in parallel, each with two groups in series. No resistances are used, the various speeds being obtained by the grouping of the cells. The capacity of each cell is 150 ampère hours. At the normal rate of discharge, 25 ampères, the charge suffices for a run of about six hours, covering a distance of 40 miles, at a speed of about 8 miles per hour. The motor consists of a 3½ H.P. series wound; on each end of the armature spindle is a pinion which, by means of chains, transmits the motion to the rear wheels. The weight of the vehicle in working order is 3,120 lbs., of which the battery weighs 1,330 lbs., or about 440 lbs. per E.H.P. All the machinery is well cased in and protected from dust. The vehicles are under perfect control, a single lever at the driver's left hand being all that is necessary to stop and start the car, or reverse it, or to apply the electrical brake. The steering arrangements are simple and efficient, and enable the vehicle to be turned completely in a little more than its own length. There are two powerful band brakes applied by foot to the two rear road wheels, thus preventing any undue wear to the indiarubber tyres.

The Oppermann Victoria.

The cost of recharging the accumulators at 1½*d.* per unit is about 2*s.*, there being no difficulty in obtaining the necessary electric supply at this rate, as a number of these vehicles would form an excellent means of providing a "day load" for municipal and other electric lighting undertakings.

One of these carriages has been running in Paris for the past three months, during which time its hill-climbing properties have been amply tested, with most satisfactory results; on one notable occasion ascending to Belleville and returning with four passengers to the heights of Montmatre, commencing at Rue Lepic and following the cable tramway; also ascending from the bridge up to the entrance of the Trocadero, a gradient of 1 in 7, or 14 per cent.

One most important feature was the entire absence of "side slip," accounted for by the makers by the very sensitive steering arrangements; for during the end of February and early part of March there was a spell of very wet weather, and the carriage was out every day, doing an average of 30 miles per day. During a trial run, a distance of 45 miles was traversed in the streets of Paris with one charge of the cells. The whole of the mechanical part of the carriage, including the motor, controller, gearing, wheels, and axles, were specially designed by the inventor, and constructed at his works in Clerkenwell. The body of the carriage, which is finished in superb style, was made by Mr. Arthur Mulliner, of Northampton.

We may mention in conclusion that on Mr. Oppermann's arrival in Paris recently with his Victoria he was immediately approached by the representatives of certain French capitalists, with the result that a company has been formed to run these vehicles in Paris. Every one will congratulate Mr. Oppermann on his well deserved success.

CONDENSERS FOR STEAM-VEHICLES.

Messrs. Thornycroft and the Steam Carriage and Wagon Company, of Chiswick, have patented an ingenious system of air condensers for use in steam vehicles. The following description is taken from the patent specification :—

The object of the invention is the construction of surface condensers, in which steam can be readily condensed by the action of air coming

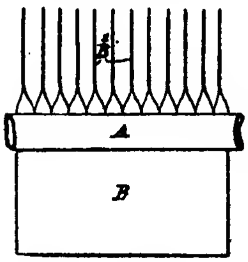

Fig. 1.—Side View.

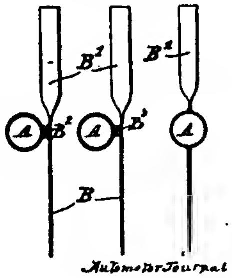

Fig. 2. Fig. 3. Fig. 4.

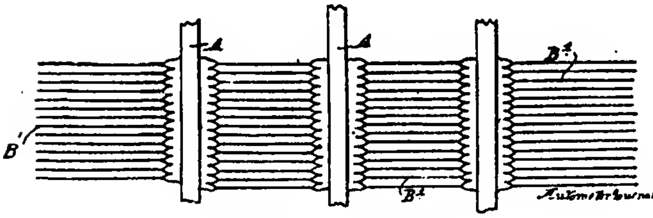

Fig. 5.—Side View of Condenser.

in contact with steam-containing portions of the apparatus. Such a condenser is made with thin tubes of metal that is a good conductor of heat; the tubes are constructed with a series of thin fins or gills that project outward laterally to a distance that is considerable in comparison with the diameter of tube, these lateral projections being so arranged that between them spaces are left for the passage of air, which, impinging upon the exposed surfaces, will take up heat from the steam that is in the tubes, and so cause condensation.

Referring to the accompanying drawings—Fig. 1 is a side view of a portion of an air-condenser tube, and Fig. 2 is a transverse section. The tube, A, is made with one or more extremely thin flanges, B, wide as compared with the diameter of the tube, and running its entire length, these flanges being cut transversely at short intervals into a number of narrow parts, B¹, each of which is at its inner end integral with the tube, and is twisted, as shown at the upper part of Fig. 1, so that there are formed a series of lateral projections, with spaces between them that will allow currents of air to pass, and will present efficient surfaces for the air to act against. The tube, A, is formed in one with its fins, B¹, from a thin sheet of copper bent to a tubular form, with a flange projecting tangentially on each side of the tube seam, which is soldered, as shown at B² in Fig. 2.

Fig. 3 illustrates a modified construction, in which the fins are made separate from the tube, and the two parts are joined by solder, as indicated at B³. Fig. 4 illustrates a further modification, in which the tube, A, and fins are made in one piece, the tube being made complete without soldering, and the fins being arranged to extend diametrically therefrom, and tapered towards their outer edges.

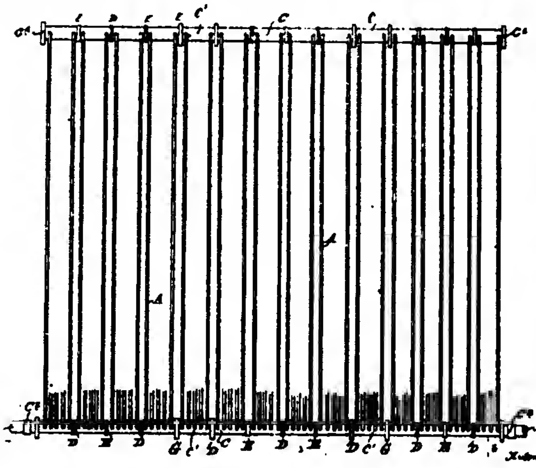

Fig. 6.—Plan of Condenser.

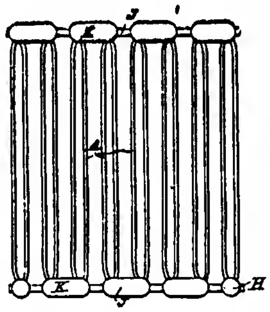
Fig. 7.—Section on line a—b.

The inventors have found that tubes with small fins or gills, such as described, give a much better result than an equal extent of surface not so subdivided. It will be understood that the surface of each lateral projection constitutes a small area which, by reason of the arrangement adopted, is traversed by air that has not just previously been flowing over another portion of surface belonging to the same tube.

Fig. 8.



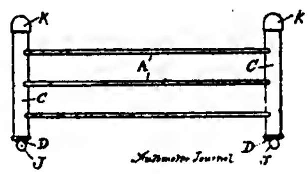


Fig. 9.

Fig. 5 is a side view of a portion of a set of condenser tubes so provided with fins; the tubes, A, are soldered to one side of a thin metal plate as shown, and the fins of the several tubes in the set are formed by making a series of short parallel slits in those parts of the plate that lie on each side of and between the tubes, A, and twisting or bending the strips of metal to the required angle. Condensers according to this invention can be constructed so that the flow of air may be that due to the passage through the air of vehicles carrying such condensers, or the flow of air may be caused by fans, blowers, or exhausters. Special provision is made for readily and automatically removing the water of condensation as the steam is condensed. A convenient arrangement of condenser comprises a number of transversely arranged tubes having fins or gills, these tubes being connected at their ends in series by longitudinal tubes provided with diaphragms to cause the steam to flow from one

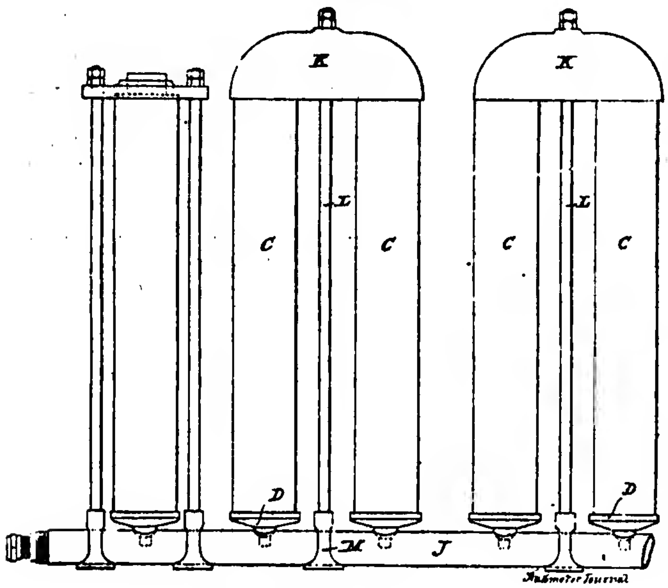

Fig. 10.

longitudinal tube through one series of transverse tubes to the other longitudinal tube, and thence back again by another series of transverse tubes and so on; small holes being formed through the diaphragms to enable the water of condensation to flow along the longitudinal tubes to suitable points whence it can be conveyed to the feed or water tank.

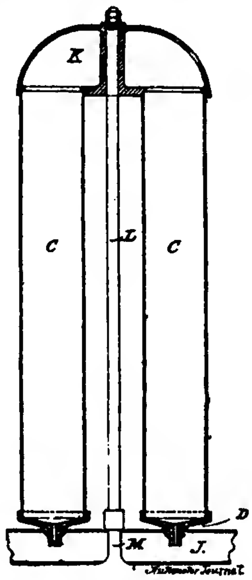

Fig. 11.

Fig. 6 is a plan of such an arrangement of condenser, and Fig. 7 is a section on the line, a—b, Fig. 6, and which are respectively a plan and a rear elevation of a modified construction of condenser in which the tubes, C, that connect in series the transversely arranged tubes, A, having fins or gills are vertical, the lower ends of each tube, C, being provided with a funnel-shaped diaphragm, D, the outlet portion of which is let into a pipe, J, adapted to lead off the water of condensation that passes through the diaphragms. The tubes, C, on each side of the condenser are connected in pairs at their upper ends by junction pieces, K, as illustrated in Figs. 10 and 11, which are detail views to an enlarged scale. The junction pieces are secured by rods, L, that screw at their lower ends into sleeves, M, embracing the pipes, J, and at their upper are fitted with tightening nuts as shown. It will be seen from Fig. 8 that the arrangement is such that steam admitted at H will be caused to flow in a zig-zag fashion through all the sets of transverse tubes, A, as in the previously described arrangement.

The following claim is made:—An apparatus for condensing steam made with thin tubes of metal that is a good conductor of heat, which tubes are constructed or provided with a series of thin fins or gills that project outward laterally to a distance that is considerable in comparison with the diameter of tube, these lateral projections being so arranged that between them spaces are left for the passage of air which, impinging upon the exposed surfaces, will take up heat from the steam that is in the tubes and so will cause rapid condensation.

The specification is numbered 25,489 of 1896.

AN EARLY ELECTRICAL CARRIAGE.

The accompanying illustration is reproduced from an old engraving of a carriage propelled by primary batteries, which was tried on the Edinburgh and Glasgow Railway in 1842. It cannot be said to have been a great success, as the maximum speed attained was only four miles an hour, but it is, nevertheless, of considerable interest as being the first electrical carriage, on a practical scale, ever constructed.

Model carriages had certainly been made before that date. Davenport, an American, in 1835, constructed one adapted to run on a circular railway; this was exhibited in this country in 1838. Botto, an Italian, Sturgeon, and Clarke had likewise constructed working models before 1842. Clarke's model was exhibited at work upon a circular railway in Leicester.

The particular machine we are now dealing with was the invention of a Mr. Davidson, of Aberdeen. It weighed, complete, 5 tons, and was 16 feet long by 6 feet wide. The drawing shows the construction and action pretty clearly. The armatures were composed of cylindrical blocks of wood, into which were inserted longitudinal bars of iron spaced at 120° apart.

The electro-magnets are not one solid piece of iron, as is generally the case, neither are they rounded behind. Each of the side parts, or arms, is constructed of four plates of soft iron, put together so as to form, as it were, a box, for the sake of lightness. The arms are 25 inches long, and joined together behind by plates of iron. Their rectangular poles measure 8 by 5 inches, and at their nearest points are only about 4 inches asunder. The coils with which they are surrounded do not consist of a single copper wire, but of bundles of

T 4

wire wrapped round with cloth to ensure insulation. According to Mr. Davidson's first arrangement, these magnets were placed so that their poles were nearly in contact with the revolving masses of iron in their transit; but so prodigious was the mutual attraction, that the means taken to retain the magnets and iron in their assigned positions were insufficient. They required to be more firmly secured, and their distances had to be somewhat increased, by which considerable power was lost.

The electro-magnets of each pair were energised alternately in the manner shown in the upper figure.

Near each end of the axle which passes through the large cylinder are two smaller cylinders. Each of these cylinders has the half of its rim next to the larger cylinder entirely covered with metal, so that it is a conductor of electricity. The outer halves, O O′, are only partly covered with metal, the intervening portions being of ivory, well-baked wood, or some other non-conductor of electricity. We shall suppose the dark spaces on the belts, O′ O, to represent the conducting parts, and the white spaces the non-conducting parts. Now, suppose one end of the wire which is coiled round the iron, M, to be connected with Z, one pole of a battery, and the other end of that wire, *a*, to rest on *c*, the metallic rim of the right hand small cylinder, while the wire, K*b*, from the other pole of the same battery rests on a metallic part of the rim O; in this case the circuit is complete.

The batteries comprised 59 elements, each consisting of a plate of amalgamated zinc placed between a pair of iron plates. The dimensions of the plates were 15 inches by 12 inches. Means for elevating the plates out of the liquid were provided.

EXPLOSION OF A STEAM TRAMCAR BOILER.

The following account is taken from the official report of the explosion of a steam tramcar boiler at Birmingham, on December 21st, 1897. As will be seen from the accompanying illustration, the boiler is of the locomotive type, made of iron throughout, except the tubes, which are of brass, and the fire-box and fire-box stays, which are of copper. The barrel is 2 feet 9 inches external diameter, and 3 feet 3 inches long; the dimensions of the external fire-box are—length, 2 feet 7 inches; width, 2 feet 11 inches; and height, 3 feet 10 inches; and those of the internal fire-box are—length, 2 feet 2¼ inches; width, 2 feet 6¼ inches; and height, 2 feet 7 inches. The sides of the fire-box are supported by stays screwed into the plates and riveted at each end, and the top of the box by similar stays screwed into the plates and fitted with nuts at their lower ends. The plates are $\frac{7}{16}$ inch thick throughout, except the tube plates, which are ⅜-inch and ½-inch thick, respectively.

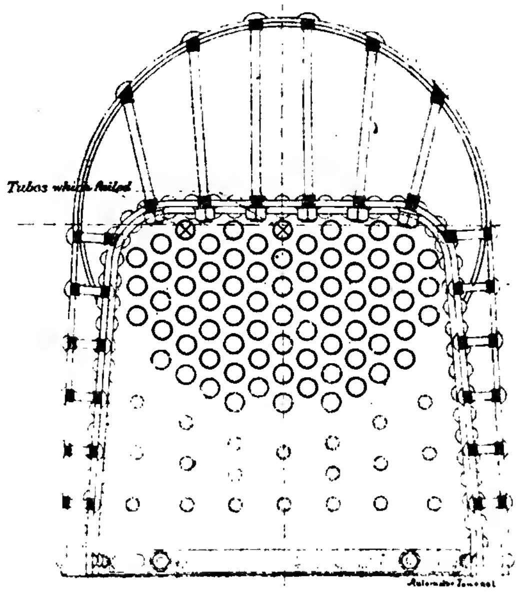
The longitudinal joint of the barrel is made with double butt straps, double riveted, and all the other seams are of the lap description, single riveted. There are 73 solid drawn tubes, 1⅜ inches external diameter, and about 3 feet 5 inches long between the tube plates, fitted with ferrules at the fire-box ends. These tubes were said to be made of a mixture of 70 parts of copper and 30 parts of zinc; their original thickness was 11 S.W.G. at the fire-box end, and 13 S.W.G. at the smoke-box end. The boiler was fitted with the usual mountings, including a pair of spring coiled safety valves, which were set to blow at 165 per square inch. The boiler was made by Messrs. Kitson and Co., of Leeds, in 1884, but has since been repaired by other firms. It was insured with the Scottish Boiler Insurance and Engine Inspection Company, of Manchester, and was examined by them every 12 months. In January, 1897, it was examined and tested by hydraulic pressure to 250 lbs. per square inch.

In addition to the above, the engines are brought into the tramway depôt once a week, when the boilers are washed out, the tubes swept, and any repairs that may be required are attended to. At the same time the Company's boiler-makers look them over, and it is the practice, from time to time, to test the condition of the tubes by means of a bent lever, which is inserted into the mouth of the tube for this purpose. The explosion consisted in the collapse and rupture of two of the tubes at the fire-box end, the positions of which are shown on the accompanying drawing, and through the openings thus made steam and hot water escaped, severely scalding the driver. The explosion was due to the tubes having become so thinned on the fire side near the fire-box tube plate that they gave way at the ordinary working pressure. Their wasting was probably due to the scouring action of particles of coke carried through them by the draught, and to the corrosive action of the sulphurous gases given off by the fuel.

At the time of the explosion the engine was standing at the Birmingham terminus of the tramway, in readiness to take up passengers and commence a new journey; nothing wrong had been noticed with respect to the boiler, when the tubes suddenly collapsed without any warning. The pressure of steam at the time is said to have been about 145 lbs. per square inch, and it is probable that one of the tubes failed first, and the consequent shock then caused the collapse of the other.

The life of brass tubes in this class of boiler varies considerably according to the nature and conditions of the work done, and in this instance the tubes have lasted longer than those in many similar cases have done, but, as in other boilers belonging to this Company, tubes have worked satisfactorily for still longer periods before renewal, the worn-out condition of those that have now failed was not suspected.

When weighed, the collapsed tubes were found to have lost about 30 per cent. of their original weight, but the chief wasting had been localised at the part near the fire-box tube plate, where the thickness was no greater than that of paper.



Section Showing Tube Plate.

In his observations, the Engineer-in-Chief of the Board of Trade, Mr. P. Samson, M.I.M.E., &c., says:—"It is well known that brass tubes in boilers of this type are subject to a wasting action by which they are frequently worn out in a comparatively short time. The deterioration in this instance seems to have been less rapid than usual, and those responsible for the safety of the boiler, though, no doubt, aware that the tubes must have been getting thin, appear to have relied on the tests which were made by the boiler-makers for the detection of any which were entirely worn out.

"Such tests, if applied systematically and to all the tubes at sufficiently frequent intervals, are no doubt of great value for the purpose intended, especially when supplemented by the drawing of samples from the box of which the loss of weight and actual thickness can be accurately determined.

"A water test of less than double the working pressure, unless applied at very short intervals, is of little use as a means of detecting the condition of thin brass tubes, inasmuch as the local wasting is often rapid, and the strength of the tubes when hot is considerably less than might be inferred from the fact of their satisfactorily withstanding a cold water test, such as that applied in this instance."

NAUTICAL AUTOMOBILISM.

Fire Floats.

The London County Council have adopted the report of the Fire Brigade Committee recommending the conditional acceptance of Messrs. Yarrow and Co.'s offer to supply for £8,000 a fire-float containing pumping and propelling machinery. The following are the particulars of the proposed craft:—The length of the vessel will be 100 feet, the beam 18 feet, and the draught about 1 foot 7 inches, and it is estimated the speed will be from 9 to 10 knots. The vessel will be propelled by twin-screw compound condensing engines, developing about 180 H.P., deriving steam from a pair of Yarrow's water-tube boilers. These boilers are also designed to supply the fire pumps, which will consist of four powerful Worthington duplex pumps, each capable of discharging 500 gallons per minute, any one or more of which pumps may be started as occasion requires and worked at full power. These pumps will deliver into a discharge pipe connected with a water tower or large air vessel in the forward part of the craft. and from which a series of branches will be carried with shut-off valves connected with any required number of fire-hoses in action. On the top of this large air vessel will be mounted a water-tower ladder, the two sides of which will be formed by water pipes delivering at its topmost end and through two 2-inch nozzles. The direction of these nozzles can be varied according to the instructions of the fireman at the top of the ladder by lifting, depressing, or swinging the water ladder from the deck. Branches will be taken underneath the deck from the pump delivery pipes to either side of the vessel forward or aft. The valves will be arranged in such a manner that the pumps may be made to discharge overboard at any of the four orifices provided, so that the vessel may be manœuvred to starboard, port, or broadside on. The vessel will be fitted with steam steering gear, steam winch, towing apparatus, and provided with two small boats, and the craft will be built of the same class of material at present used by Messrs. Yarrow and Co. for light vessels constructed for Her Majesty's Government. The propellers will be fitted in raised tunnels on either side of the vessel, so as to obtain the advantage of the lightest possible draught, and to ensure the capability of manœuvring near shore.

The Thames Automobiles.

The service of steamboats on the River Thames has at length commenced operations, and boats are now running between Chelsea and London Bridge and Greenwich. The service is now conducted under much more favourable auspices, the Company running the boats being very strong financially, and therefore able to effect those improvements in the boats which were so much wanted. The Company in question is really an offshoot of the Thames Ironworks and Shipbuilding Company, of which Mr. A. Hills, the well-known philanthropist, is chairman. This gentleman, as an ardent temperance and vegetarian advocate, has, as his first reform, abolished the "bars" which used to form such a feature, and a needless one at that, of the "penny steamer." All the boats have been overhauled and generally improved during the past winter, and the fleet now comprises 35 vessels, including three new ones, named the "Alexandra," "Boadicea," and "Cleopatra." As these vessels are intended for "above-bridge" boats, their dimensions, &c., have been adapted for that special service. They are each 125 feet long between perpendiculars, with a beam of 17 feet, a depth of 7 feet 9 inches, and a displacement of 100 tons, at which their water draught will be 2 feet 6 inches. They have flush decks from stem to stern, the height between the deck and the floor of the saloon being 7 feet.

Being paddle-wheel vessels, they are fitted with oscillating engines, having surface condensors; the engine cylinders are 23 inches diameter, with a piston stroke of 2 feet; steam of a working pressure of 30 lbs. per square inch is supplied by two cylindrical return-tube boilers, the object of these being in duplicate is to keep them entirely under the deck, which, conjointly with the engines, being as low in the vessel as possible, provides a spacious promenade—on deck—on each side right fore and aft. In previous boats of the class the boiler casings and engine-room skylights have been so wide that only a narrow gangway was left on each side, making the embarking and disembarking of passengers very inconvenient. This is now obviated by the improved boiler and engine arrangements, the skylights over these compartments being made no wider than just sufficient for light and ventilation.

It was at first proposed to fit these "above-bridge" boats with compound engines, but through the requirement of frequent starting and stopping at a number of piers, it was after careful consideration concluded that they would not be so convenient as the low-pressure type of engine, nor more economical in fuel through the shortness of run between stoppages. As the engines are surface condensing, each boat is fitted with a circulating pump driven by an independent motor, a large double-acting pump for wash deck and fire purposes, and a dynamo and engine for supplying the current for an electric installation throughout the vessel.

Below the deck each boat has two spacious saloons, the after one being 38 feet long, and the forward one 31 feet, both of the full width of the vessel; a commodious temperance refreshment bar, lavatory, &c, are provided in the after one.

As their engines will indicate about 150 H.P., the speed expected to be realised by these boats is 12 knots.

HORSE AND MOTOR-VEHICLE ACCIDENTS.

The Dangers of Driving Nervous Horses.—As Mr. Thomas Kank, of Leyland, was driving down Fishergate, Preston, in his dogcart, on March 29th, his horse was startled by a motor-vehicle, which passed it. The animal dashed down the street and collided with a lorry. The trap was wrecked, and Mr. Kank was pitched head first on to the pavement. The horse proceeded down Fishergate with the broken shafts trailing after it, but was stopped by a man, who, however, failed to retain his hold of the animal's bridle. Turning round, it dashed up Fishergate, and when passing the Town Hall fell and fractured one of its legs. By order of a veterinary surgeon it was poisoned. Mr. Kank was removed to the infirmary, where he remained in an unconscious condition. His injuries, it is feared, are of a serious nature.

A Similar Case.—On Thursday morning, the 31st ult., as a two-wheeled covered cart belonging to Messrs. Ford and Amor, contractors, was being driven through Basinghall Street, London, it collided with another van, causing the horse to bolt. The driver was thrown between the shaft and the horse, the wheel passing over his neck. He was killed instantaneously. Another man was thrown out of the back of the cart and was taken unconscious into an office close by.

A Bull in a China Shop.—While an ox was being driven through Islington on the 17th ult. it met a motor-cab, the driver of which tootled on his horn. This evidently terrified the bull, as with tail erect it rushed across the road, scattering the passers-by in all directions, some of them falling over one another in their eagerness to get out of the way. The bull then took a course down Chapel Street, and charged at a stall loaded with vegetables, overturning the lot, which were at once spoiled, as they, most of them, landed in a heap of street refuse which was piled at the side. The unfortunate woman who kept the stall was pinned to the ground by the stall. The bull then charged on, knocking over a man and a boy who had pluckily rushed to the assistance of the woman. They sustained a severe shaking. The bull next turned its attention to some piles of crockery ware, which had been stacked up on some sacking in the gutter for the day's market. In a very few minutes the greater portion of the crockery had been reduced to atoms, whilst the luckless owner was standing on the top of a van close by swearing as loudly as he could, and calling on the some half-dozen men who had been plucky enough to follow the bull, to shoot or strangle it in some way, or he would have the law on them. The man was in such a state of abject terror that, notwithstanding the seriousness of the situation, the men roared with laughter at him. A few moments after this the two drovers appeared on the scene, and also three or four constables. The bull stood at bay amongst the crowd, but by dint of a little manœuvring a constable succeeded in lassoing it, but not before the bull had managed to pull several people to the ground. The drovers then took him in hand, and in a very few minutes managed to lead him away amidst great excitement.

U

THE EFFICIENCY OF BICYCLES.

PROFESSOR R. C. CARPENTER has recently pnhlished the results of an extended series of experiments on bicycle efficiency, which he has conducted at the Sibley College of Cornell University. Starting with the bearings, he found the loss here to be very small, being hut $\frac{1}{5}$ to $\frac{1}{10}$ per cent. of the work transmitted when light machine oils were used, and from $\frac{6}{10}$ to $\frac{7}{10}$ per cent. when the lubricant was a mixture of graphite and lard. This frictional loss appeared to he entirely independent of the speed. The chain efficiency at ordinary loads and at high speeds was found to range between 93 to 97 per cent., with chains in good oondition. A dirty chain, however, usually wasted 10 to 15 per cent. more in friction than the above; though much seemed to depend on the make, as one of the specimens tested worked practically as well when old and dirty as when new. Until the recent improvements in gear-cutting machines, no bevel gears were as efficient as a good chain; even now, in none of his experiments has Professor Carpenter found a bevel gear with a higher efficiency than a good chain, whilst medium quality chains are much superior to medium quality bevel gears. In one test of a high quality chainless machine, tested at 15 miles per hour, and receiving from 20 to 280 foot-pounds per minute, the work lost in friction ranged from 10 to 18 foot-pounds per revolution, whilst with a similar quality chain wheel the loss was hut 7 to 5 foot-pounds per revolution. The highest efficiency noted for a chain gear was 97 per cent., and for two pairs of bevel wheels 94 per cent. Independent experiments by Professor Denton, made under conditions particularly favourable to the bevel gears, showed very similar results, as, though these latter proved slightly superior at very high loads, the chain had the advantage when tested at the usual riding loads. The greatest difference in the efficiency of different machines is to be found in the tyres. Thus, one wheel running at 14 miles per hour, and taking $\frac{1}{4}$ H.P., showed a total efficiency of 42 per cent. On changing the tyres this was increased to 54 per cent., and a second change brought the figure up to 60 per cent. In another case a change of tyres hrought up the total efficiency of a bicycle from 42 per cent. to 75 per cent., which is the highest total efficiency noted in the experiments. As to the power required to move the hicycle, Professor Carpenter estimates that at 5 miles per hour, on a good level road, a rider does work at the rate of about 840 foot-pounds per minute; and at 10 miles an hour the work done, even with an allowance for wind, will not be more than 1,336 foot-pounds per minute. Hard continuous riding needs 4,500 foot-pounds per minute, whilst for a short period a good rider can do work at the rate of 11,000 foot-pounds per minute.—*Engineering.*

Motor-Tricycles *v.* Trains.—Mr. James Tuke, of Bradford, a well-known automobilist, writes:—"I left Bradford at 9.30 on Wednesday, 17th ult., for York on a 1898 pattern 'New Beeston' motor-tricycle. Arrived in York at 11.30, did husiness in York and got lunch; left York 1 p.m., arrived in Bradford 3 p.m., 35 miles each way: total, 70 miles, four hours' running. Had I gone by train I could not have been back till 4·17. Owing to change at Leeds the trains take two hours each way. How is this for a record?—17½ miles per hour kept up four hours."

The Local Authority Again.—At a recent meeting of that august legislative body, the Bedford City Council, a Mr. Potter called attention to the dangerous riding of bicycles in the town, and hoped some bye-laws would be passed to prevent it. A Mr. Burridge thought some attention should also be given to the motor-cars. The Town Clerk said there were already bye-laws dealing with these matters. It is really very curious to observe that directly a local tradesman obtains a seat in the city council he seems to be consumed with an overpowering desire to make bye-laws regulating either his neighbour's dog, mangle, housemaid, or something else which is *not* his.

SARGEANT'S WATER-TUBE BOILER.

MR. W. S. SARGEANT, of Chiswick, is a well-known builder of steam launches and of river craft generally, and as such has acquired a deservedly high reputation. Some years ago, when the secondary battery became a commercial and practical fact, he built and ran a small fleet of electric launches on the Thames, charging the batteries at a small station situated within his premises. When the era of water-tube boilers and high pressure of steam commenced, Mr. Sargeant went into the matter and experimented largely, his object, as was that of other constructors, being to design a boiler which would be lighter and more powerful than the ordinary multi-tubular boiler. With the passing of the Locomotives on Highways Act, Mr. Sargeant saw that the field for the use of small light cheap high-powered boilers was enormously enlarged, and at length he has succeeded in constructing a boiler which we have no hesitation

FIG. 1.—SARGEANT'S BOILER.

in saying, as the result of practical demonstrations carried out in our presence, meets the requirements of builders of motor-vehicles intended for heavy traffic in a most satisfactory manner.

As will be seen from Fig. 1, the boiler consists of an upper drum and two side chambers connected together by tubes resembling, so far as external appearances, a Yarrow water-tube boiler. There are, however, some novel features which differentiate it from this and other similar types. Within the upper drum is a kind of basin which serves as a separator and prevents water from passing into the main steam pipe. As the water within the tubes is heated steam is formed, and in rising carries with it globules of water into the upper drum. The steam and water, however, impinge upon the outer surface of the basin and the water falls, the steam rising and collecting in the steam space. The lower part of the upper drum is connected with the side chambers by a bifurcated downcomer, which, being away from the source of heat, acts as a means for circulating the water. The upper drum and side chambers are of Siemens-Martin steel, the latter being dished to shape. The drum is 3 feet 3 inches long by 10 inches diameter. As will be seen, the ends are flanged and closed by covers, and additional support is afforded by a longitudinal screwed and nutted stay. There are 330 steel tubes $\frac{3}{4}$ inch diameter, and of No. 16 gauge. The total length of tubing is over 800 feet. The total heating surface is 135 square feet. The normal working pressure is 250 lbs. per square inch, and steam of 100 lbs. can be raised from all cold in ten minutes. Such a boiler can be fitted with a fire-grate if required to burn solid fuel, but Mr. Sargeant recognises the advantages of liquid fuel in that its evaporative power as compared with coke or coal is, roughly, twice as great, while it can be more conveniently carried both in launches and in motor-vehicles. It also enables the heavy iron fire-bars to be dispensed with. Mr. Sargeant's patent burner acts on the regenerative principle and is automatic in its action, while from its construction it does not readily get choked by the deposition of carbon; should this occur the deposit can easily be removed even while the burner is hot. The oil is supplied to the burner from the tank by an air-pressure of 7–10 lbs. per square inch obtained by working a small air-pump. The consumption of ordinary burning oil, *i.e.*, refined petroleum having a flash point of 73-80° F., is 8 pints per hour.

FIG. 2.—SARGEANT'S STEAM MOTOR.

The following are the weights of this boiler:—

	lbs.
Weight of boiler, burners, and mountings, empty	907
Weight of contained water	110
Total weight	1,017

Several boilers of this type have been very successfully applied to motor-vehicles with most satisfactory results, and further orders are on hand. We hope to say more about their performances for this purpose on a future occasion.

Mr. Sargeant also makes an exceedingly light and compact steam motor suitable either for launches or motor-vehicles. We illustrate this in Fig. 2. As will be seen it consists of a pair of open-fronted compound engines, the cylinder being 3¾" + 7½" × 5½" stroke. A piston valve is fitted to the H.P. cylinder, and an ordinary D slide to the L.P. cylinder. The cylinders are jacketted, and the tops and bolts are covered with aluminium covers which gives a very neat appearance. The cranks are balanced and are of steel, as are the connecting rods, which are hollow. The link motion is of a plain and substantial kind of the Stevenson type, the links being solid slotted. The feed is worked through reducing gear off a crank at one end of the shaft, and is a gunmetal construction. With a boiler pressure of steam of 250 lbs. per square inch the engines run at 500 revs. per minute, and give off about 35 I.H.P. The weight of the engine as shown in the condition in the drawing is 600 lbs. with pumps.

The above-described engine and boiler have been fitted in a remarkably well-built launch, designed and built by Mr. Sargeant, and named the "Daring." This vessel has been built to the order of Mr. F. May, of Messrs. Grant and May, of Billingsgate Market. She is built of teak throughout, and is designed on the lines of an Admiralty pinnace. She is 36 feet long, 7 feet beam, with a draught of 2 feet 9 inches. The machinery and boiler are placed amidship with feed water tanks in the sides. The fuel tank is placed in the bows and is cased in. The space before and abaft the machinery will accommodate a large party, and when awninged over the vessel will make a delightful river cruiser. The propeller is an ordinary three-bladed bronze one while the rudder is a single steel plate. Speed 13½ knots.

In concluding this notice of Mr. Sargeant's machinery we have devoted so much space to it as it will be observed that he has produced an engine and boiler of great power on a weight of considerably less than one ton.

Testing Tyres.—Of the inventions relating to tyres there is no end, and much puncturing is a weariness to the flesh. At last we have, so the daily Press informs us, an absolutely unpuncturable tyre manufactured by the A.B. Company, of Coventry. The properties of this remarkable tyre were demonstrated recently before a large company of journalists, who were so much overcome with what they had witnessed that—so says the *Scottish Wheel*—several of the leading journalists rushed forward to the managing director and to the courteous manager of the factory and demonstratively congratulated them on the great triumph which the Company had achieved and their luck in being the possessors of such a marvellous invention. A good tyre of the pneumatic type is much wanted for light motor-vehicles, but whether the "A.B." tyre would answer the purpose we do not know. Judging from the account of the "tests," these seem to have been anything but scientific or practical in their character, and to us they demonstrate nothing of value. It is a rather curious thing about these and similar public "tests," "trials," and so forth, that representatives of the technical Press are never invited to witness them.

Mr. Sturmey's Trip.—In one of the interesting articles published in the *Autocar*, describing his recent trip through the length and breadth of the land, Mr. Sturmey gives the following useful information:—Total distance traversed, 929 miles; average speed, 10 miles per hour nearly; consumpt of petrol, 67·5 gallons, or 1·72 pints per mile. The motor was of 4 H.P.

Motor-Car and Cycle Company.—It seems to be a growing fashion for many firms who deal as agents in cycles to place this legend over their shop door, but rarely are any motor-vehicles to be seen inside. At best these agents can only quote for motor-cycles, and why they should persist in calling these by that hybrid name motor-car it is difficult to imagine.

Newspaper Motor-Vehicles.—Messrs. W. H. Smith and Son, the well-known newspaper and periodical distributors, of the Strand, London, employ in various parts of the country many hundreds of carts and vans, and the cost of the maintenance of so many horses is necessarily very great. They have decided to give motor-vehicles a trial, and have just placed an order with Messrs. Julius Harvey and Co., of 11, Queen Victoria Street, who have been so successful with the Post Office in carrying the mails in their famous "Lifu" van.

NOTES OF THE MONTH.

The Midland Cycle and Motor-Car Exhibition Company are paying a dividend of 80 per cent. on the share capital.

Among the smaller craft sent out by Germany for service in Chinese waters are a couple of naphtha launches.

According to a statement in the *Autocar*, it is very unlikely that the Daimler Motor Company will pay any dividend at all this year.

Says a Manchester exchange:—"The motor-car is making headway. There have been several in the Manchester streets lately, chiefly for advertising purposes. Now big concerns like John Heywood's and Sutton's are using them instead of the usual horse and wagon for the delivery of goods. No doubt we shall hear shortly of other firms following this example, and perhaps before long we may have motor-cabs such as are already in use in Paris and London."

As there may be many opportunities for the use of aluminium in engineering work where a bright surface is not required, it may be of interest to many engineers to know how this metal may be easily blackened. The process is as follows:—The metal having been carefully cleaned with glass paper, a coat of olive oil is applied to it, and it is then heated till the oil boils. When a yellow colour has been thus obtained, a second coat of oil is applied, and the metal is strongly heated till it turns black. The oil is then wiped off.

From a Melbourne paper we learn that a motor-vehicle has at length made its appearance in that city. In it were Mr. J. Pender, of Brunswick, and Mr. Edwin Phillips, the patent agent. Mr. Pender, who was in charge, appeared to have thorough control of the vehicle, and steered round the corners and through the many vehicles at the intersection of Swanston and Collins Streets with great skill. The conveyance, which seats two, is of American manufacture, and has four pneumatically-tyred wheels, the rear pair of which are operated by a two-cylinder horizontal explosion engine, consuming stove oil. It is the first of its kind in the colony.

In view of the visit of the Messrs. Barnum and Bailey's Show to Manchester, a light railway of standard 4 feet 8½ inch gauge has been laid through Trafford Park, wherein the performances are to be given, from the main entrance, near the Chester Road, to Barton. The railway, four miles in length, thus establishes communication with the tramway systems on the two sides of the Ship Canal, and provides convenient facilities of approach from many large centres of population. Vignole rails have been laid by the Trafford Park Estate Company, and the British Gas-Traction Company will work the railway with cars driven by compressed gas.

It would seem that in France a new malady has developed itself, which may be termed Petrol Motor Mania. Signs that it has crossed the Channel and is likely to be epidemic with us are also not wanting. From our French exchanges we learn that scores of patents are being taken out, and thousands of pounds being spent in experiments to perfect or improve upon the petrol motor. Indeed, most of our French contemporaries rarely describe a steam motor, but the number of petrol motors they describe and illustrate is legion. Yet we confess we rarely see any really novel or useful departure made, and as they all work on the Beau de Rochas cycle much improvement is not possible.

As the result of negotiations which have been going on for some time, the Dundee and District Tramway Company have placed an order for a motor-vehicle with a Scottish firm, and it is expected that it will be available for service in the course of a few days. According to the arrangement entered into some time ago, the tramways will fall into the hands of the Corporation 15 months hence, and, having regard to the changed situation, the directors have been giving consideration to the question of finding an outlet for the shareholders' money. It has been decided to experiment with an oil motor-vehicle, and one of the type built by Mr. Stirling, Hamilton, has been ordered. The vehicle will be something after the style of a wagonette, and will be capable of accommodating eight persons.

Tests are now being made abroad with mats of felt, which are designed for laying under the rails of street railway lines for purposes of protection and sound deadening. The new mat, which is a German invention, is described as being made of strong wool, which is thoroughly impregnated with oils, then superficially coated with glue which has been rendered insoluble by the addition of sodium bichromate and formaldehyde, and then very highly compressed to form plates from ½ inch to several inches in thickness, and of various sizes. They are especially recommended for crossings and bridges, and it is claimed that they tend to prolong the life of the rail by lessening the wear on it. The surface of the mat is said to be so hard that a rail may be placed upon such a piece of matting without cutting into it. The material is known by the name of iron felt.

In the eyes of the uninstructed scribe, every vehicle which is not drawn by horses is a motor-car, and hence cable cars and electric tramcars come under this description; and so it is not surprising that the *Morning Advertiser* should say, in its issue of the 19th ult.:—

"*Killed by a Motor-Car.*—At Douglas, yesterday, an engineer named Cæsar Brew, employed by the Isle of Man Electric Tramway Company, was attempting to jump on an electric motor-car, when he slipped and fell on the line. The car went over his head, almost severing it from his body. Death was instantaneous. The car was being shunted at the time. Brew was a middle-aged man, and leaves a wife and family."

It may be as well to point out that the electric car runs on rails, and weighs about 4 tons; the motor-car, as generally understood, weighs perhaps less than 1 ton, and is not confined to one part of the road, and hence can avoid such accidents.

PRICES OF MOTOR-VEHICLES.

The *Engineer* in a recent issue gives the following prices of the most modern French-made motor-vehicles:—

Description.	No. of seats.	H.P.	Price. £	s.	d.
Carriage..	2	3	187	4	0
Carriage, with hood ..	2	—	199	13	6
Dog-cart	4	—	208	0	0
Wagonette	4	5	228	16	0
Vis-à-vis..	4	—	249	12	0
Omnibus	4	—	249	12	0
Wagonette	6	—	249	12	0
Delivery van	—	—	249	12	0

An additional sum of £8 6*s.* 6*d.* to £25 is charged, according to the number of seats, when fitted with indiarubber tyres. The carriages have generally three grades of speed—slow, moderate, and quick. The petroleum used is called the essence of petroleum, with a specific gravity of ·70, and costs 4½*d.* per quart. Some employ naphtha, costing ½*d.* more per quart, and the cost of running is about ½*d.* per mile.

DOINGS OF PUBLIC COMPANIES.

The "Taxameter" system is likely to be shortly introduced to London, as a private syndicate has recently been formed with a capital of £20,000 to exploit this "much-needed want." The directors are Messrs. Frederick R. Sims, H. H. Stanley Evans, H. Sherwin Holt, and C. Harrington Moore, the registered offices being at Donington House, Norfolk Street, Strand. As it is stated these taxameters are to be fixed in a large number of cabs, including the new electrical vehicles, the advantages put forward by the Company will be fully appreciated by regular users of cabs, and we are inclined to agree with the management when they say that the cabman who has this novel and useful instrument fixed in his vehicle is likely to secure the largest number of fares. It renders overcharge impossible, the instrument always clearly showing the exact fare payable; it records the number of journeys and distances traversed; the day's total earnings; and as it can be set when hired to record either by distance or time, we hope very shortly that the disputes and scenes which are so continually taking place in regard to the proper amount payable to the cabman will become a remembrance merely of bygone days.

Midland Cycle and Motor-Car Exhibition.—The second annual meeting of the Midland Cycle and Motor-Car Exhibition Company (Limited), was held on March 30th at the Grand Hotel, Birmingham. Mr. J. B. Burman presided, and the other directors —Messrs. W. Calcott, R. F. Hall, F. H. Parkyn, J. H. Price, F. Westwood, J. Urry, and C. Wheelwright—were also present. The directors reported that the last exhibition was in every way a success, and they again recommended the payment of a dividend of 80 per cent.

The Salocin Patent Carriage-Wheel Company.—Under a winding-up order made against this Company, the statutory meetings of creditors and shareholders were held last month at the Board of Trade Offices, Lincoln's Inn. It appeared that the Company was registered in July, 1896, with a nominal capital of £50,000, and was formed to acquire from Mr. F. Klingelhöfer certain patents relating to the Salocin wheels for carriages, motor-cars, &c. It was promoted by Mr. P. H. V. Nicholas and the Salocin Syndicate. The purchase price was fixed at £40,000, and this consideration was to be divided as follows:—Mr. Nicholas, £20,000 in cash or shares; the Salocin Syndicate, £10,000; and the vendor £10,000. Only 4,300 shares were applied for, and upon that the Company went to allotment. The cash consideration could not be paid, and the purchase price was ultimately discharged as follows: To the vendor, £500 in cash, £9,500 in shares, and £1,500 in debentures; Mr. Nicholas received £19,100 in shares, and the Salocin Synndicate £9,400 in shares. The liabilities were returned at £1,118, and the assets at £697, but the latter were subject to a debenture for £516. As regarded shareholders, there was stated to be a total deficiency of £41,801. Mr. F. H. Pollexfen, accountant, was appointed liquidator under the proceedings.

Electrical Street Car Manufacturing Syndicate (Limited).—The statutory meeting of this Company was held on the 8th inst., at the works, Wodnesfield Road, Wolverhampton. The Chairman, Major Flood Page, thought that the speed and success with which the new works and offices had been erected and equipped indicated great energy and skill on the part of those of his colleagues who had directed the work. They had got excellent premises. The amount of money subscribed in cash was a little over £7,000. They were probably witnessing the commencement of a very great advance in electrical matters, and he was sure that electric traction in the streets would in a few years cause a great diminution in the number of horses so engaged. They only required a good accumulator and good business management. The fact that Mr. Parker was engaged in the undertaking gave it an element of certainty. He thought that their prospects were excellent. In four or five years' time there would hardly be a horse-drawn omnibus in the country. The London omnibus companies had incomes amounting to over a million, and they represented the business which the Syndicate was waiting for. He thought that the younger shareholders present would live to see the day when that business would attain vast proportions, comparable even to that of the London and North-Western Railway Company.

British Electric Traction Company (Limited).—The second ordinary general meeting of this Company was held on April 7th at the offices, Donington House, Norfolk Street, Strand, Sir Charles Rivers Wilson, G.C.M.G., C.B., presiding. The Chairman, in moving the adoption of the report and accounts, said he was glad to be able to state that at the end of their first year they had already succeeded in establishing a business of considerable magnitude, and one which they had every reason to believe would become very profitable to the shareholders. The gross profits amounted to £14,422, and after deducting such of the general expenses as were chargeable to revenue, and also the expenses incurred in connection with schemes and undertakings which had been initiated but eventually dropped, there remained a profit of over £9,800. In proceeding to give particulars of some of the important schemes the Company was developing, the chairman said that foremost among them were the enterprises in Staffordshire. In the Potteries district they had made arrangements with the North Staffordshire Tramways Company for the electrical equipment of its lines, and had obtained a provisional order, which had been confirmed by Parliament, and a light railway order for considerable extensions; so that their scheme in the Potteries now embraced all the principal towns, and covered a total route of upwards of 36 miles of tramways and light railways. With regard to the South Staffordshire scheme, they made an arrangement with the South Staffordshire Tramways Company by which the working of the portion of that Company's lines which was already electrically equipped was transferred to this Company. With regard to the Dudley and Stourbridge Tramways Company, they had purchased practically all the shares in that Company, and were virtual owners of it. The lines were being worked at present by steam as heretofore, but the necessary arrangements had already been made with all the local authorities, except Dudley Corporation, for the adoption of electric traction on those portions of the lines within their respective jurisdictions, and steps were being taken to equip and work electrically the line from Brierley Hill to Stourbridge. The whole of this South Staffordshire scheme when carried out would embrace the total mileage of upwards of 50 miles of line. After referring to the arrangements which had been made in connection with the Company for the adoption of electric traction in several other parts of the country, including Oldham, Ashton, and Hyde, in the neighbourhood of Manchester, Kidderminster, and Stourport, Hartlepool, North Shields, Gateshead, Paisley, Cork, and Crewe, the chairman said it would serve to give the shareholders some idea of the magnitude of the business they were engaged in carrying out when he told them that they had upwards of 50 different schemes under consideration, and that the agreements and contracts they had entered into, and the concessions they had either obtained or applied for, covered a total mileage of electrical tramways and light railways in the United Kingdom of upwards of 200 miles, and it was not looking very far into the future to say that a total capital expenditure of between £2,000,000 and £3,000,000 would have to be provided. In conclusion, the chairman pointed out the disadvantages attending the municipalisation of tramways, observing that undertakings of this kind, which often necessarily extended into several districts, could be much more satisfactorily worked by private enterprise.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

Automatic Conveyance Company (Limited).—Registered by H. J. Comyns, 9, Gracechurch Street, E.C.; capital £6,000, in £1 shares. Object, to enter into an agreement with F. H. Briggs, and to manufacture and otherwise deal in oil-engines, oil-motors, &c.

Taxameter Syndicate (Limited).—Registered by Castle and Co., 15, Duke Street, St. James's; capital £20,000, in £1 shares. Object, to carry on business as manufacturers of and dealers in taxameters and other fare and distance indicators for cabs, cycles, and other vehicles.

Surrey Machinists Company (Limited).—Registered by H. B. Vaughan, 132, St. John Street, E.C.; capital £1,000, in £1 shares. Object, to acquire the business carried on as the Surrey Machinists Company, and to carry on the business of cycle manufacturers and dealers, motor and carriage builders, &c. Registered office, 71, Mansion House Chambers, Bucklersbury, E.C.

r 3

Paris Automobile Cab Company (Limited).—Registered by Mills and Co., 11, Queen Victoria Street, E.C.; capital £10,000, in £1 shares. Object, to enter into an agreement with J. P. Juvenet, and to manufacture, sell, and deal in motor-carriages, motors, cycles, and carriages of all kinds. J. P. Juvenet is the managing director.

The New Rossleigh Cycle and Motor Company (Limited) (Scotch Company).—Capital £50,000, in £1 shares (10,000 six per cent. preference shares). Object, to take over the assets and undertaking of the Rossleigh Cycle Company (Limited), and to carry on the business of manufacturers of and dealers in cycles, motor-cycles, motor-vehicles, &c.

Devon Traction and Motor Company (Limited).—Registered by G. P. Cooper, 1, Budge Row, E.C.; capital £25,000, in £1 shares. Object, to enter into an agreement with R. C. Fenton, J. E. Parnell, and W. J. Dart, and to carry on the business of hauliers, traction-engine, and motor proprietors. The first directors are R. C. Fenton, J. E. Parnell, and W. J. Dart.

British Automotive Proprietary Syndicate (Limited).—Registered by Marshall and Marshall, 3, Lincoln's Inn Fields, W.C.; capital £55,000, in £1 shares. Object, to adopt an agreement between the Automotive Syndicate (Limited) of the one part and this Company of the other part, and to carry on in all or any of their respective branches the businesses of builders of electric, steam, gas, oil, and other motors.

Dare Manufacturing Company (Limited).—Registered by R. E. Watt, 61, Chancery Lane; capital £2,000, in £1 shares (1,000 preference). Object, to acquire the business carried on by H. B. Hoch, at 14, Borough High Street, S.E., as the Dare Manufacturing Company, and to carry on the business of cycle manufacturers, motor and carriage builders, &c. Registered office, 14, Borough High Street, Southwark, S.E.

Hopkins, Taylor, and Co. (Limited).—Registered by T. T. Hull, 22, Chancery Lane, W.C.; capital £2,000, in £1 shares. Object, to acquire the business carried on by R. F. Taylor, R. C. Hopkins, C. H. Wiley, and P. Everitt as Hopkins, Taylor, and Co., and to carry on the business of motor manufacturers, motor manufacturers, &c. The first directors are R. C. Hopkins (managing director), R. F. Taylor (chairman), C. H. Wiley, and P. Everitt.

Jesse Ellis and Co. (Limited).—Registered by Powell and Co., 28 and 29, St Swithin's Lane; capital £60,000, in £1 shares. Object, to carry on in all or any of their respective branches the businesses of carriage builders, rubber merchants, manufacturers of and dealers in cycles and other vehicles or the component parts thereof. The first directors are F. J. Beadle, R. J. Fremlin, J. Ellis, and T. Scott. Registered office, Invicta Works, Maidstone, Kent.

Ribblesdale Cycle Company (Limited).—Registered by Jordan and Sons (Limited), 120, Chancery Lane, W.C.; capital £25,000, in £1 shares. Object, to acquire the business carried on by T. Shutt and R. Ryden, at Whalley Banks, Blackburn, Lancashire, as the Ribblesdale Cycle Company, and to carry on the business of cycle manufacturers and dealers, motor and carriage builders, &c. Registered office, Whalley Banks, Blackburn, Lancashire.

Motor Omnibus Syndicate (Limited).—Registered by Gibson and Co., 27, Chancery Lane, W.C.; capital £6,000, in £1 shares. Objects, to acquire, own, and work Edwerd H. J. C. Gillett's interest in Patent No. 21,302 of 1896, for "improvements in water tubes or sectional steam boilers," to construct, purchase, equip, maintain, and work omnibuses, vans, &c. The first directors are:—A. V. England, C. Hayles, and W. R. Manning. Registered office, 27, Chancery Lane, W.C.

Yachtsmen and Automobilism.—Writing on the recent yacht races at Cannes, a correspondent of the *Yachting World* says:—"On Thursday (the 18th ult.) we were invited by the Mayor and Corporation of Cannes to witness the ceremony of laying the foundation stone of the new Jetée by H.R.H. the Prince of Wales, our Vice-Commodore, making the journey from Nice to Cannes in a motor-car. I notice that yachtsmen in France are fond of this kind of locomotion, and are encouraging an epidemic of nervous complaints by scouring the country at the rate of 23 miles an hour. Our Vice-Commodore says he does not wonder that yachtsmen take to motor-cars, they are so like a sailing boat; when they are in full swing you cover a lot of ground, but it is a good deal like going to sea in a 2½-rater: when you will reach your destination or under what conditions you will eat and sleep depend upon an unfathomable number of contingencies."

CONTINENTAL NOTES.

The Panhard vehicles entered for the Paris-Amsterdam contest will be of 8 H.P., and weigh each 1,650 lbs.

The Municipal Council of Saint Gilles has authorised the employment of five motor-vehicles at the Midi Railway Station.

The Societé des Ateliers Germain have constructed a tractor of great power for towing lighters on the rivers and canals.

The Cie. Scotte has had to remove its workshops to larger and more commodious premises at La Rue d'Hautpoul, Javel à la Villette.

The Kriéger Company is actively engaged in building electrically-propelled cabs for Paris. They have no less than 22 vehicles in course of construction.

A Motor-Car Exhibition is being organised by the French Automobile Club, and is to be held in Paris next June. Over 30 firms have already applied for space.

The Société des Automobiles et Moteurs Henriod, with a capital of £20,000, and the Société des Voiturettes Automobiles Schmidt, with a capital of £12,000, have lately been formed.

The firm of MM. Chasson et Cie. (L'Agence Générale des Automobiles) have despatched to the Caucasus a motor diligence of 12 H.P. It is intended for the public service. Three other vehicles are to follow.

The Committee of the Automobile Club has adopted, on the motion of M. Paul Meyan, the proposal to hold a Concours des Petits Poids in May, 1898. No vehicle can be entered that weighs more than 440 lbs. empty.

In Belgium steps are being taken to establish lines of motor-omnibuses in various districts, and the authorities are favourably regarding the scheme. These omnibuses will each carry 20 passengers and their luggage. The roads are to be specially remade for these vehicles.

The latest thing in automobilism is the project of a wealthy Californian to reach the North Pole in an automotor vehicle. We are expecting to hear of another enterprising American who will explore the Sahara or the great Australian desert in a similar conveyance.

The Automobile Club of France is taking up the subject of speed indicators, and has invited makers to submit instruments specially suitable for motor-vehicles, for trial at the hands of a technical committee. A strong, accurate, and not too expensive speed indicator is much wanted.

A sign of the Times.—Outside the Velodrome at Courbevoie one read till lately, "Au rendezvous des cyclistes." This has been replaced with "Au rendezvous des automobiles." This may be rendered, Good accommodation for man and motors. Where is the British hotel-keeper sufficiently enterprising to write such a legend over his door?

The following firms have applied for space at the Exposition of Automobiles to be held on May 25th next:—Panhard et Levassor, De Dion-Bouton, De Dietrich, Georges Richard, Clément, Houry, Kriéger, Léon Bollée, Automobiles Peugeot, Mors, Leblond, de la Forêt, Société l'Automobile, Mouter, Decauville, Jeanteaud, O'Kelly, Popp, Cambier, Englebert, Léon Lefebvre, Brouhot, Chceslier, Société Industrielle; the total space required for motor-vehicles being 24,750 square feet.

The Automobile Club, Bordelais, has organised a meeting for May 29th and 30th next at Agen, which promises to be a big affair. The civic authorities of Bordeaux will offer gilt medals for competition, and there will be fêtes in connection with the more serious business of automobilism.

In consequence of the difficulty experienced by the French railway companies in classifying motor-vehicles for carriage, the following definition has been adopted:—A motor-cycle is a vehicle mechanically propelled, of a weight less than 440 lbs. empty. Above this the vehicle is classed as a voiture.

L'Energie Électrique, in its issue of March 16th, gave an excellent monograph on the life and work of M. Gramme, the distinguished French electrician, and the father of practical electricity. We remember having worked some of the earlier Gramme dynamos, which at that time were the best in the market.

As showing the remarkable increase in the use of cycles in France, we may say that in 1893 there were 130,480 machines, and the tax on these amounted to 941,362 francs. In 1897 the number of machines had risen to 303,562, the tax being 4,060,000 francs. In 1898 it is estimated that there were 400,000 cycles in use.

A writer in *La France Automobile* says:—To obtain the maximum effect in the new tricycles of De Dion et Bouton having about ¾ H.P., it is better to give as little admission of gas vapour to the cylinder as possible, as too much gas means a large increase of heat and a loss of power. Inexperienced *chauffeurs* frequently make the mistake of giving a too large admission.

We have received a copy of a new French paper entitled *La Vie au Grand Air*—an illustrated review of all the sports. It is excellently printed, and approaches in many respects our English standard of such journals. It, of course, deals with automobilism, but in a popular way. Yachting is another sport that is well described. In the number of its sporting papers France is emulating Great Britain. In both countries serious journalism is apparently declining, the public preferring matter which makes no demand upon the reflective faculties.

The Northern Railway Company of France has built a small electric railway tractor for shunting purposes in the large railway stations. It consists of a truck mounted upon four coupled wheels. The battery is composed of 64 cells of five plates each, each cell being of ebonite. A special commutator enables the cells to be arranged in various groups by which four different speeds can be attained. The motor is placed in a cabin with its spindle vertically, and drives the main axle through bevel gearing. On the level the tractor will easily maintain a speed of 12 miles per hour for six hours. It will haul from one to 12 wagons or carriages with ease.

With the growing use of motor-vehicles in France there has arisen among the more enthusiastic automobilists a dislike to the use of the term "horse-power," as reminding them too forcibly of that animal which all true automobilists regard as distinctly unsuited for traction purposes in towns. It is proposed to employ the poncelet as the unit of power. The poncelet is, we may remark, ·763 of a horse-power. Owing, however, to the inherent conservatism of makers and users, the new word is not likely to become general for many years. Our contemporary *L'Energie Électrique* has announced its determination to employ the poncelet in conjunction with the horse-power.

An attempt has been made to remove the name of M. Zola, the distinguished *littérateur*, from the membership of the Touring Club, but we are glad to see it has failed. *La France Automobile*, among other papers, protested vigorously against what we have no hesitation in describing as a mean and ignoble action. Besides, it would have, if successful, made a bad precedent. If there be one means more useful than another in softening political and religious asperity, it is in bringing men of diverse views together, who are, however, interested in some common object. If automobile, cycling, and touring clubs do nothing else, they at least in this way exercise an invaluable humanising and civilising influence.

In civilised France the influence of the Press in promoting automobilism is justly recognised, and we observe with pleasure that M. Paul Meyan, the distinguished editor-in-chief of *La France Automobile*, has been presented with a medal for his services in connection with the Marseilles-Nice Races, and MM. Villemot, Aubry (*Les Sports*), and Aimé, well-known writers on automobilism, have also been decorated by the Automobile Club. M. Aubry especially deserves this honour, as, apart from merely chronicling the doings of automobilists, he has contributed a great deal to the literature of the subject of automobilism in general. We congratulate him and his colleagues on a well-deserved recognition.

During the Marseilles-Nice Concours the mayors and magistracy of the various towns and districts through which the vehicles passed courteously, and very wisely, suspended any local regulations as regards speed. It was a special occasion, and hence the law could very properly be temporarily suspended. The magistrates, however, reserved themselves full liberty of action. The result was that no one was killed, the competitors were delighted, and the public, whose servants the magistrates are, were satisfied. In Great Britain such a course of action is impossible. A special Act of Parliament would be required; our unctuous magistrates would be shocked at the idea. The only occasions on which the local laws can be suspended in this country are during riots, and when, owing to an election, a horse race, or some other equally valid reason, an extension of time is permitted to the local publicans.

THE LANCASHIRE STEAM MOTOR COMPANY'S ROAD WAGON.

(BY OUR OWN CORRESPONDENT.)

In response to the joint desires of your Editor and the Lancashire Steam Motor Company, I journeyed recently to Leyland (Lancs.), where the works of the Company are situate, to witness the trial of a new road wagon made by the Company for heavy traffic. There was a representative gathering in some ways, though in point of numbers it was limited. Just before my arrival two gentlemen had witnessed a trial of the wagon on behalf of the Dundee Steam Tram Company, and had expressed themselves as pleased in every way. Mr. Spurrier, the courteous and enthusiastic manager of the Company, then gave me every opportunity to seek information, and arranged with Mr. Sumner, who was in charge of the wagon, for a trial run on behalf of The Automotor, of which he evidently has a good opinion both as an engineer and an ardent automobilist.

Shortly after, several other gentlemen joined us, including Mr. Deakin (Bo'ness), an enthusiastic amateur automobilist, and the Hon. Sec. of the S.P.T.A. (Mr. Shrapnell Smith, Liverpool). Numerous runs were then made, and the loaded wagon put to the test on some steep gradients. The roads were very heavy, so that I consider the tests *were* tests. In looking through a report made to the Chelsea Vestry on motor dust vans, which Mr. Spurrier passed to me for inspection, I was pleased to see that the Leyland van is one of the two commended to the notice of the Vestry. This is not altogether surprising, as I noted that in the matter of price the Leyland firm was well away from all competitors. For instance, one dust van was tendered at something over £600, to mount a gradient of 1 in 20, whereas the Lancashire Steam Motor Company's offer was to climb 1 in 7, in a van costing £320. *Verb. sap.* To come to the road wagon under consideration, however, the illustrations give a very good idea of the wagon as a whole, but the following items of general interest will be found useful. The tare is just under 3 tons, which is the limit fixed by the Locomotives on Highways Act. It will carry a load of 4 tons, under which it is capable of making 6 miles per hour on the level and of climbing a gradient of 1 in 7. The average speed comes to about 4½ miles per hour. As the Parliamentary speed limit for wagons of this capacity is 5 miles per hour it will be evident that there is an ample margin on the right side.

The inspection of this wagon was rendered all the more interesting by the fact that it was not merely made for demonstration purposes, but was made for Messrs. Fox Bros. and Co. (Limited), of Wellington, Somerset, to whom it was delivered a few days after the trials which I witnessed were made. It is fitted with double brakes, the reserve brake being operated by a hand-wheel on the steering shaft; the latter is thus quite independent of the automatic brake, which is applied by the same lever that cuts off steam. Either of them will stop the wagon in half its length, or hold it on an incline of 1 in 7.

The wagon is 18 feet long and 6 feet 2 inches wide, the loading space being 13 feet by 6 feet 2 inches. The total height is 10 feet 6 inches, and from the floor to the top of the cab 4 feet. The wheels, which are steel tyred, are 3 feet 4 inches in diameter, with a 5 inch tread. It is built on a steel frame, giving a platform area of 78 square feet. The loading platform is fitted with side and tail boards, which are hung on hinges, and can be let down at once for loading or unloading. Moreover, they are so hinged that they can be removed in a minute, and the vehicle used as an ordinary lorry.

Passing next to the equipment which supplies the motive power; the principles involved are similar to those embodied in the steam van which the Company entered in the Royal Agricultural Society's trials last year, gaining the Society's Silver Medal (the only award), and which was reported in The Automotor.* The boiler is of the Company's patent vertical fire-tube type, and has 110 square feet of heating surface, *the weight per square foot of surface being 6 lbs.*

The working pressure is 200 lbs. per square inch, the boiler being tested by hydraulic pressure up to 450 lbs.

The Lancashire Steam Motor Lorry.

With the feed tank it carries about 40 gallons of water, and owing to the highly efficient "Row" tube condenser on the top of the cab, only wants replenishing once a day. The inside can be removed for cleaning without touching the steam fittings.

Common petroleum is used as fuel. The burner employed is fairly silent, as such burners go. It is very economical, the combustion of the oil being perfect, and unaccompanied by the constant drop-drop-drop of unburnt oil, which proves so wasteful with some petroleum burners. As regards being noiseless, it is a distinct advance upon the burner used at the trials last June.

In this way steam can be raised in 18 minutes, from water at the ordinary temperature, to the necessary pressure of 200 lbs. The water is fed in by a small brass pump which gives a constant feed, while the flow of oil to the burner is controlled automatically by a diaphragm-valve, which is operated directly by the pressure in the boiler. This arrangement is simplicity itself, the working pressure being kept absolutely constant, without the slightest attention on the part of the attendant, be he skilled or unskilled, thus reducing to vanishing point any risk that might otherwise be attached to the use of a boiler of the "flash" type. The consumption of oil ranges from $1\frac{1}{4}$ to $1\frac{3}{4}$ gallons per hour. It never exceeds the higher limit. The oil used is the ordinary refined petroleum, such as "Royal Daylight," "Anchor," or "Tea Rose," which can be obtained in the most out-of-the-way places, in an emergency, and bought in bulk at $3\frac{1}{2}d.$ per gallon. The oil reservoir holds 15 gallons—more than enough for a full working day.

The engines are of the compound vertical enclosed type, giving 18 I.H.P. (14 B.H.P.) at 400 revolutions per minute. They are lubricated by an ingenious automatic device. The bearings are specially constructed, and a small pump driven from the main shaft forces the lubricating oil through special channels to the driving-shaft journals, and other parts of the engines. At full speed the pump supplies the oil at a pressure of 5 lbs. to the square inch, gradually diminishing as the speed varies. All running parts practically work in a bath of oil, and there is only a trifling loss, which is compensated by re-charging the lubricating oil-holder every two or three days.

The gearing gives three speeds—$1\frac{1}{4}$, 3, and 5 miles per hour.

The wagon is practically noiseless and very free from vibration, even when standing still. It runs evenly and without any emission of waste steam or smoke. The steering arrangements prove that the wagon is absolutely under control, its behaviour at the sharpest of corners and on broken ground was in every way reassuring, and showed a great advance on the steering at the R.A.S.E. trials. The runs made in the neighbourhood of the works gave every satisfaction to those who watched them, and drew commendatory remarks from the Hon. Sec. of the S.P.T.A. and others who were present. The wagon is a distinct advance in the heavy branch of automobilism, and the makers, I understand, are ready with several improvements for the next wagon, with a view to increasing efficiency by a free use of aluminium alloys, of which the engine bed is constructed in the present case. There is only one suggestion, if I might be allowed to make one, and that is to put two circular sight glasses in the back of the cab. They would greatly simplify running backwards, the backing of the wagon up to loading platforms, and the like. They would be available with the majority of loads, as only very bulky ones would come high enough to obscure the back view, and would always be useful when returning light.

* *See* Vol. I, p. 473.

A Sportsman's Exhibition.—Under the auspices of the London Exhibitions (Limited), what was ironically termed a Sportsman's Exhibition was held for a few days recently at Earl's Court. Of course, motor-cars were advertised as an attraction, but the whole thing was, as an exhibition, most disappointing. If the exposure of a few goods used by horsemen and others, with the inevitable automatic machines, the side shows in which cheap jewellery and sweets are retailed by pert young women, the whole being contained in a corrugated structure resembling a mission hall, constitutes an exhibition, then this was undoubtedly one. The show was bare and tawdry in the extreme. Barring a few river boats, such as scullers and punts, there was nothing worth looking at. The Daimler Company had six motor-vehicles of various types arranged in a side passage; and in spite of their fine appearance, due to the lavish expenditure of paint and varnish, they looked for all the world like a row of carriages at Aldridge's waiting to be disposed of by auction. What legitimate purpose is served by such so-called exhibitions it would be hard to say.

SOME RECENT IMPROVEMENTS IN ACCUMULATORS AND THEIR APPLICATION TO TRACTION ON COMMON ROADS.*

Means of vehicular locomotion by the aid of some power other than that of horses is a subject that is now receiving a vast amount of attention. Not only is it of interest to electrical and mechanical engineers and carriage builders, but it has been taken into serious consideration by all those responsible for the regulation of traffic in our large towns. The subject is of such huge importance that it not only affects those whose business or pleasure calls for some rapid and safe means of transport from place to place, but it affects the safety and comfort of the ordinary pedestrian as well. Our present system of horse traffic is open to many objections not only from a humanitarian point of view, but from its sanitarian and economic aspect as well. The streets in our large towns would present a vastly different aspect if, instead of horses, some other means of drawing our vehicles were used.

Much attention has been given to the application of steam, petroleum, and spirits to produce the necessary motive power, but there is but little doubt that electricity will eventually supersede them all, not only on the score of economy, but owing to its freedom from heat, steam, disagreeable odour, and to the ease with which it can be manipulated.

Electro-chemical generators may be divided into two distinct types, viz., primary and secondary. In a primary cell the electrical energy is developed by the direct chemical decomposition of the excitant or electrolyte and one or both of the elements, the magnitude and rate of such electrical development being chiefly dependent upon the chemical activity of the materials employed.

The secondary, storage, or accumulator cell, as it is variously called, is the name given to that class of apparatus which is quite inert in itself, but on passing an electrical current through it certain chemical changes are induced which render it capable of receiving, retaining, and the redeveloping a certain amount of electrical energy. The ratio between that amount of energy put in and returned is dependent upon the chemical activity and nature of the materials employed, and also the mechanical construction of the cell.

Secondary batteries may be divided into two classes, viz., those in which the active material is formed from the substance of the element itself, either by direct chemical or electro-chemical action, and those in which the chemical formation is accelerated by the application of some easily reducible salt of lead. Elements of the former type are usually termed "Planté," and those of the latter "Faure" or pasted, Messrs. Planté and Faure being the respective inventors.

The active materials in all the best known types of secondary cells, whether of the Planté or Faure pattern, is peroxide of lead in the positive element, and spongy lead in the negative. The medium through which the necessary chemical changes occur during either a charge or discharge is a solution of sulphuric acid and water. There is still much doubt as to the precise nature of the chemical changes involved in a lead sulphuric acid cell, due to the action of an electric current, and therefore this matter will not be discussed here. Enough, however, is known to enable those concerned in their commercial manufacture to construct cells of almost any electrical capacity, and capable of taking up and giving out any rate of charge or discharge. It is now usual to speak of any given type of secondary cell as being of so many ampère hours capacity per pound of plate, or per pound of complete cell. In the latter case the precise nature of the containing vessel, whether it be of glass, earthenware, metal, or vulcanite, must, of course, be specified.

Planté Cells.

The Planté original secondary cell was of an extremely simple nature, consisting merely of two long strips of thin sheet lead placed one upon the other. To prevent contact between these lead strips a piece of coarse felt was placed between them. This plate was rolled up into the form of a cylinder, and was immersed in a solution of one part of pure sulphuric acid to 10 parts of water. The "forming" process was managed in the following way :—The current was caused to pass through the cell until gas was freely given off from the lead plates. On examining the elements, that plate which had been joined to the positive pole of the charging source was found to be coated with a thin film of peroxide of lead. The plate which had been joined to the negative pole was scarcely altered in appearance, neither did it have any electrical capacity. At each successive charging the peroxide on the positive plate was found to sink deeper into the metal. This "eating in" operation was allowed to go on until a sufficient amount of peroxide was formed, or, in other words, until the requisite capacity had been obtained.

In all cells of the Planté type little or no difficulty is experienced in "forming" the positive element. With a negative element, however, the case is very different. Here the active material is chemically spongy lead, and it is only by repeated oxidising and deoxidising the metal surface that the necessary depth of this finely-divided lead can be obtained. This is the difficulty experienced in all forms of Planté cells.

The original method employed to produce the desired quantity of active spongy lead was a system of charging, allowing to rest, and then reversing the current through the cell. By each reversal of current the peroxide is reduced by the nascent hydrogen liberated on its surface during the decomposition of the solution, first into the lower oxide, and then into metallic lead in a very finely-divided state. At each successive reversal this oxidising and reducing action sinks more deeply into the substance of the lead, and by careful treatment any desired depth of active material may be obtained. To form plates by the above process is an exceedingly long, tedious, and therefore expensive operation, and many workers have exercised much ingenuity in devising methods to accelerate the forming operation. To this end Planté himself tried a large number of experiments, the most successful being a preliminary treatment of the lead with dilute nitric acid to thoroughly scour and roughen its surface, and the application of heat to the cell during its formation to open the pores of the metal and allow the electrolyte to penetrate more deeply into it. This, then, is the original secondary cell from which our present-day accumulators have been evolved.

One of the earliest to introduce into this country a commercial cell of the Planté type was Mr. Epstein, and a cell bearing his name has been long on the market. Mr. Epstein has given much attention to the production of accumulators of this type, and in a recent communication to the Institution of Electrical Engineers he promised to shortly introduce an improved form of his plate, which he stated was particularly suitable for traction purposes. Such a promise, coming from one so well versed in the subject, leads us to expect a real improvement. The original Epstein plate was made by deeply grooving both sides of a lead plate. The plate, when grooved in this way, was boiled in a solution of nitric acid and water, or some similar solution. This process is said to so corrode the metal that it is easily acted upon electrolytically. Owing to the serrated nature of the plate, the active material appears to wedge itself in the narrow grooves, and does not fall out under ordinary working conditions.

The Crompton-Howell cell, which we do not hear much of now, was constructed of plates sawn from a cast mass of porous lead. We believe this material was prepared by a system of aerating the metal while in its molten condition. The resulting plate was of a highly porous and crystalline nature, and, owing to its porosity, the electrolyte easily permeated it, thus rendering the formation quite an easy matter.

A form of cell now on the market, known as the "D. P." accumulator, manufactured by the D. P. Battery Company, is also of the Planté type. The elements in this case consist of a large number of narrow strips of lead built up one above the other. By this method a large active area, enabling the cells to be charged and discharged at high rates, is obtained, while disintegration of the active material or buckling is said not to occur. As in the case of the Epstein cell, the plates are chemically treated to accelerate the formation.

The traction cell made by this Company is not designed with a view to extreme lightness, but rather with the idea of combining durability with as little weight as possible. The containing case of this particular form of cell is of ebonite, and it contains three plates —one positive and two negative. The weight of the complete cell is about 33 lbs., and three cells are put in a crate for convenience of handling, the weight of the three thus fitted being about 100 lbs.

The capacity of each cell is 100 ampère hours, at a normal discharge rate of 15 ampères; they can, however, the makers state, be discharged at any rate within reason that may be desired without damage to them, the only consequence being a loss in capacity as the discharged rate is increased. The makers assert that with this form

* Excerpt of a paper by Mr. J. T. Niblett, M. Inst. E.E., and read before the Liverpool Centre of the Self-Propelled Traffic Association by the Hon. Sec., Mr. E. Shrapnell Smith, on March 20th, 1898.

of cell a current capacity of four ampère hours per pound of plate, and three ampère hours per pound of complete cell, is obtained.

The "Lamina" accumulator elements, as manufactured by the Lamina Accumulator Company, are made up of a series of perforated and corrugated lead strips. The method of making these plates is somewhat as follows:—Lead is received in the form of rolls of 8 to 10 inches wide, and of varying thickness of from 1-64th to 1-32nd of an inch. The lead is first perforated, and is afterwards corrugated by a suitable machine. After being treated in this way the lead is cut up into strips of the desired size. These strips when built up are encased by a sheet of perforated lead, held in position by leaden rivets, and lead-burnt at the top and bottom.

The forming process is said to take only 36 hours. As the mechanical construction of the plates is simple and strong, they are said to withstand quite well the severe work imposed upon them when used for traction purposes. The makers state that a cell of this form of construction can safely be charged or discharged in one hour. The following data of the Company's "A s" traction cell may be of interest. The containing case is of ebonite, and is of the following dimensions:—10½ inches long, 4¼ inches wide, and 12 inches deep. The complete weight of the cell, with elements, and electrolyte is given as 40 lbs. The dimensions of the positive plates are as follows:—8½ inches long, 7¾ inches wide, and ⅜ of an inch thick. The size of the negative plates are:—8½ inches long, 8¼ inches wide, and ⅜ of an inch thick. The discharging rate of this form of cell is 20 ampères; but it may be run up to 100 ampères. The normal charging rate is 25 ampères, but this can also be run up to 100 ampères.

The various types of Planté cells just described are a few of those best known in our own country, and most of these are being used more or less extensively for electric traction purposes.

Having now briefly described the original secondary cell and its developments, we shall turn our attention to a more widely known type.

Faure, or Pasted Cells.

Camile Faure, appreciating the inconvenience incidental to Planté's electrolytic method of producing battery plates, conceived the idea of accelerating the operation by applying a layer of chemically-prepared oxide of lead to their surfaces, and then converting it into active material by the action of an electric current. Owing to the defects which speedily developed in Faure's original plates, they never came into commercial use. Much ingenuity has been exercised by various workers in devising methods of holding active material, and many of these devices have been made the subject of patents.

Messrs. Sellon, King, Volkmar, Phillippart, Parker, Swan, and others have each devised methods of holding active material on grids, frames, or plates. These methods, combined with Faure's original discovery, constitute that group of inventions owned by the Electrical Power and Storage Company, and are well known shortly as the E.P.S. patents. The elements as originally made and largely used by the above Company were perforated with a large number of square apertures, tapered inwards from both surfaces, thus forming a double dove-tail. Owing to their peculiar shape, the pellets of active material tend to key themselves firmly into the countersunk holes. The metal frames are cast in a metal chill or mould, and when cleaned up the frames are filled in with the material to be rendered active. The positive frames are filled or "pasted" in with red lead made into a paste by the addition of a solution of 1 part sulphuric acid to 8 parts water. The material used for the negative element is litharge mixed with sulphuric acid, 1 part added to 20 parts water. When dry, the plates are placed in a bath containing dilute sulphuric acid, where they are partly formed, or what is known as "hardened," by means of an electric current. After being hardened, the plates are removed from the bath and placed in a suitable frame, and their connecting lugs are lead-burned together. When treated as above, the elements are fit for sale purposes. In all cases the actual forming is done by the purchasers.

Of late years improvements have been made in the original E.P.S. plates. The King-Faure plate, now much used, has a series of ledges cast upon it on both sides, and these ledges are filled in with the active material. Plates made on this principle are much thicker than those originally made, and are said to give a greater capacity per pound of plate. The accumulators made by the E.P.S. Company, and so extensively used for electric light purposes, are so well known that they scarcely need further description here. We shall, however, have occasion to again refer to this Company's traction cells later on.

A form of accumulator which has been received with much favour on the Continent is known as the "Tudor." Of late years this form of cell has been introduced into this country, and is now manufactured by the Tudor Accumulator Company. The elements are not of the grid form, but consist of lead plates deeply grooved, made by being passed between a pair of suitably-made rollers. The grooves in the negative plate are narrower than those on the positive. When prepared in this way the plates are coated by electrolysis with a thin layer of peroxide, and the interstices are then filled in with the usual paste of lead oxide. The reason for treating the plates in this way is to prevent the formation of sulphate of lead at the junction of the metal holder and the active material. After the above treatment the plates are allowed to dry and are passed through smooth rollers. This last process closes up the grooves, and tends to key the active material in.

According to Professor Kohlrausch, who made some tests of the original Tudor cell, he found that a capacity of 1·6 ampère hours per pound of plate was obtained by a cell of the following dimensions:—The weight of the elements was 29·3 lbs., the total active surface of the positive plate was 1·29 square feet, the amount of electrolyte was 6 pints. Such a cell was stated to have an internal resistance of 0·015 ohm when charged, and 0·02 ohm when discharged. The best charging rate was found to be 5 ampères, and the discharging rate 6·5 ampères. As a mean of six ordinary charges and discharges a current efficiency of over 90 per cent. was said to be obtained. We believe that since the above test, and owing to improvements made, far better results have recently been obtained.

A material for making the elements of secondary batteries quite distinct from any of those already considered is known as lithanode. The credit of devising lithanode is doubtless due to Mr. Desmond FitzGerald, whose labour in the field of electro-chemistry is well known. Batteries, with improvements made on Mr. FitzGerald's original invention, are now made by the Lithanode Electric Storage Company.

Lithanode may be obtained in varying degrees of porosity. For high discharges it is made of a highly porous nature, the porosity being produced by incorporating in the material crystals of some salt, which is practically inert, and which is dissolved out during the forming operation.

The rate of discharge obtainable from lithanode batteries varies between very wide limits, and is regulated by the character of the lithanode, whether made hard, medium, or soft. The ordinary working rate of discharge is one-fourteenth of an ampère per square inch of lithanode plate, but owing to recent improvements very much higher rates of discharge can be obtained.

The electrical capacity of lithanode, when discharged at the above rate, is almost exactly one ampère hour per ounce, so that in a lithanode element weighing 1 lb. a current capacity of 16 ampère hours is obtained. In practice, however, this high capacity is never reached.

Thinking it may be of interest I have prepared the following particulars taken from one of the Company's most popular types of portable battery:—

Data of Complete 30 Ampère-hour Lithanode Batteries, including Wood Cases.

No. of cells.	Outside dimensions of battery.			Open E.M.F. of battery.	Approximate gross weight of battery.
	Length.	Width.	Height.		
	ins.	ins.	ins.	volts.	lbs.
1	3·75	7·00	6·37	2	8¼

Detailed Particulars of Cell.

Vulcanite containing cell	6·25 inches long. 2·12 ,, wide. 5·25 ,, high. weight, 10 ozs.
Positive element ..	Two plates in each cell, 5·9 inches long. 3·9 ,, wide. 0·25 inch thick. weight, 1 lb. 1½ ozs.
Negative elements ..	Three plates in each cell, 5·9 inches long. 3·9 ,, wide. 0·13 inch thick. weight, 11½ ozs.

Weight of connectors, 3 ozs.
Weight of cover, vent plug, sealing, and separators, 2 ozs.
Quantity of electrolyte, 15·5 fluid ozs.
Gross weight of complete cell, 6 lbs. 7 ozs.
Normal charging rate, 3 ampères.
Normal discharging rate, 3 to 4 ampères.
Maximum safe discharging rate, 9 to 12 ampères.
Approximate internal resistance, 0·015 ohm.

The data given will give a fair idea of what is obtained in actual working with this form of cell. Other batteries of larger capacity are, of course, made, and as the capacity increases, the proportional weight and bulk slightly decreases. These batteries have been used extensively for lighting vehicles, actuating coils for X-ray photography, and for propelling electric launches and light forms of motor-cars.

The Chloride Electrical Storage Syndicate make their accumulator plates on a somewhat similar plan to that adopted by the Lithanode Company. In this case, however, instead of using litharge, chloride of lead is employed to make the pellets. The method of making chloride plates is somewhat as follows:—Litharge is dissolved in acetic acid, which gives the resultant compound of acetate of lead. By adding hydrochloric acid to this solution, chloride of lead is precipitated. The precipitate is next passed through a filtering press, which squeezes out the acetic acid and leaves the chloride of lead in the shape of cakes. The cakes of chloride of lead so prepared are dried and put into melting pans with a small percentage of zinc. When melted the salt is run into a suitable mould, the result being the production of small hexagonal pellets. The pellets are next arranged in a metal chill, and an alloy of lead and antimony in a molten state and under pressure is forced into the interstices. The next process is to reduce the chloride. This is done by placing the plates in a reducing tank, alternately a cast plate, and then a plate of zinc. The zinc combines with the chlorine, forming chloride of zinc and reducing the lead salt into pure spongy lead. Originally both the positive and negative elements were made in this way, the spongy lead in the positive plate being converted into peroxide by the usual electrolytic method. Now, however, following out the prevailing fashion, the chloride plate is only used as the negative element, the positive is of different construction and is of the Planté type. The positive plate, which is cast in a mould, has a large number of holes in it. These are about three-quarters of an inch in diameter, and slightly tapered outwards on both sides of the plate. Into the cast holes are pressed small rosettes of lead. These, which exactly fit the holes, consist of lengths of pure lead strip gimped, and rolled up in the form of small coils. When all the apertures are filled in the plates are submitted to pressure in a hydraulic press, which operation keys in the rosettes. The formation is effected by joining up the plates to dummy negatives and peroxidising in an electrolytic bath in the usual manner.

Chloride cells are well known and largely used for traction purposes in America, and they are very well received in this country also.

A form of cell which is just now exciting much attention on the Continent is known as the "Marschner" cell. The Marschner battery is at present being used on the Dresden tramways, and it is said to be behaving in a very satisfactory manner. The plates are stated to consist of the ordinary oxides of lead, incorporated with powdered amber and an essential oil. This mixture is said to "set" very hard, the resultant plate being of a tough metal-like nature. On the Dresden car 144 cells of this type are being used. Each cell contains 13 plates, and is said to weigh only about 28 lbs. The weight of the complete battery is given as 5,290 lbs. Its efficiency is stated to be over 90 per cent., and if discharged at its normal rate —that is, 65 ampères—an energy capacity of 13 watt hours per pound of cell is obtained.

When devising cells for traction purposes many difficulties have to be overcome. Owing to their high initial cost, a small number of cells should be made to suffice, and these should be so constructed that they will run a vehicle for a reasonable number of hours with one charge. They should be capable of being charged and discharged at rapid rates. Above all, they should be able to withstand the jolting and jarring incidental to their being run over rough and uneven roads. The cell should be so constructed that the wash of the electrolyte does not remove the active material.

There is at the present moment an enormous field for an inexpensive cell which will combine large capacity with small weight and great solidity. Some form of mechanically solid cell seems to offer the best solution for this problem. Some little time ago great hopes were entertained that the solidity problem had been solved by the introduction of Dr. Schoep's solid electrolyte. This so-called solid electrolyte was made by adding silicate of soda to the ordinary solution, which caused it to set and become of a gelatinous nature. In this country some practical tests have been made with Mr. Barber-Starkey's method of making solid cells by substituting for the electrolyte a mixture of wood sawdust and plaster-of-paris, which when set was moistened with dilute sulphuric acid.

The accumulator known in America as the "Hatch" is of a mechanically solid nature. In this case metallic frames are not employed for supporting the lead salts, as they are held within a porous earthenware grid serrated on one side, and having small square recesses on the other. Plain lead plates are used as conductors, and these are bedded on the moist lead salts. According to this arrangement there is no clear liquid space between the elements, as the serrated earthenware plates touch one another, and are so placed that the ridges on one plate are placed at right angles to those on the other. Wooden clamping plates with indiarubber bands placed around them are fixed on the outside of each end element, and these serve to give the requisite elasticity. The "Pumpelly" cell is another American production, and in this case the mechanical solidity of the cell is arrived at by inserting plain, thick, porous earthenware plates between the elements. In this case, however, the plates are placed horizontally instead of vertically as in the "Hatch."

One great drawback to the employment of a viscous, gelatinous, or semi-solid electrolyte arises from the fact that when such substances are interposed between the plates no free circulation of the liquid is possible. In all secondary batteries, as already shown, the activity of the elements depends entirely upon chemical action, and as the electrolyte is a medium through which all these reactions occur it seems highly probable that anything which prevents its free access to the active material, or in any way impedes its circulation, must be detrimental, and consequently lead to less of efficiency and capacity.

To accurately test a storage cell is no easy matter, and unless great care is exercised very fictitious results may be obtained. A laboratory test as a preliminary may be very well, but for practical results such tests should not be relied upon. Testing under actual working conditions and for an extended period is the only reliable means of ascertaining the capabilities of cells intended for traction work.

We have already shown that no one type of cell is capable of doing all the very varied kinds of work accumulators are now called upon to do. Before building up a battery it is, therefore, wise to ascertain definitely the class of work it is intended to do, and construct accordingly.

To obtain a capacity test by discharging through a constant resistance, noting the fall of current and potential, is quite easy of manipulation, and is much used when comparative tests only are required. A more reliable method, however, is to discharge at a constant current, stopping when a prescribed fall of potential occurs. For traction work, where a uniform output for a given number of hours is required, it is very much the best plan to take the capacity of the cell in terms of watt-hours. Under these circumstances the discharging rate in watts must be kept constant. Testing for local action, noting the effect of high rates of charge and discharge, are more serious matters and require careful manipulation.

The internal resistance of a cell depends upon the total active surface area of the opposing plates, the nature of the electrolyte and its condition and temperature, and the distance between the plates.

There are many methods for determining the internal resistance of batteries. If the cells be as nearly as possible of the same dimensions, capacity, and state of charge, then two cells may be placed in opposition (poles of like polarity joined together) and their joint resistance may be measured by the ordinary Wheatstone bridge method. If the cells be exactly similar, then one-half the resistance indicated will represent the resistance of each cell.

A far more reliable and accurate means of ascertaining the internal resistance of cells is the differential method, as expressed by the following formula—

$$r = \frac{D - D'}{D} R$$

where r is the resistance required, D and D′ are the values of deflections obtained on a high-resistance sensitive galvanometer, and R expresses the value of a small but known resistance, used as a shunt.

When making tests by this method, a high-resistance potential galvanometer should be used, and one whose scale readings are either of uniform value, or whose tangents are strictly proportional to the angle of the deflections. To determine r we have to obtain a deflection, D, when the cell is on open circuit, and then obtain another reading, D′, when the cell is shunted by R, then by the formula given the internal resistance may be ascertained. The shunt resistance, R, should be small in comparison with the galvanometer coils. Good results may be obtained if the resistance of the galvanometer is, say, 5,000 ohms, and the shunt not more than 1 to 5 ohms.

The total current, or energy capacity, of a storage cell is the maximum amount of current or electrical energy which it is capable of storing, without reference to any loss that may occur by it being allowed to remain idle, nor does it take into account the rate or manner of its discharge.

The working current, or energy capacity, is that amount of current, or electrical energy, which can be obtained from the cell at any specified rate of discharge. When estimating this, the discharge is always stopped as soon as the cell ceases to do useful work. The working capacity of storage cells may vary between very wide limits.

The absolute current, or energy efficiency, of an accumulator cell is the ratio between that amount of current or energy put into it and that obtained by a total discharge, without reference either to its rate of charge or discharge, or to the time allowed to elapse between these operations.

The working current, or energy efficiency, of a storage cell is the ratio between the value of the current or energy expended in the charging operation, and that obtained when the cell is discharged at any specified rate.

In a lead storage cell, if the surface and quantity of active material be accurately proportioned, and if the discharge be commenced immediately after the termination of the charge, then a current efficiency of as much as 98 per cent. may be obtained, provided the rate of discharge is low and well regulated. In practice it is found that low rates of discharge are not economical, and as the current efficiency always decreases as the discharge rate increases, it is found that the normal current efficiency seldom exceeds 90 per cent., and averages about 85 per cent.

As the normal discharging electromotive force of a lead secondary cell never exceeds 2 volts, and as an electromotive force of from 2·4 to 2·5 volts is required at its poles to overcome both its opposing electromotive force and its internal resistance, there is clearly an initial loss of 20 per cent. between the energy required to charge it and that given out during its discharge. The normal discharging potential seldom exceeds 2 volts, and as this pressure is continually being reduced as the rate of discharge increases, it follows that an energy efficiency of 80 per cent. can never be realised. As a matter of fact, a maximum of 75 and a mean of 60 per cent. is the usual energy efficiency of lead-sulphuric-acid storage cells.

What the ordinary commercial man will be most interested in are tests which give him reliable information as to the cost of the up-keep and life of the battery; also data as to the initial cost and as to the mode of it doing its work. Such information cannot be obtained in a laboratory and has to be obtained by actual trials.

Perhaps a short description of one or two of the present applications of secondary batteries for propelling motor-cars will best serve to show the usual method of practically dealing with them.

In this country the vehicles put upon the London roads by the London Electrical Cab Company may be looked upon as a pioneer enterprise, and its development will be watched with the closest interest by all those concerned.

One of the chief novelties claimed for these cabs is the double winding of the electric motor. By adopting this system great economy of battery power is said to be effected. The starting lever on its first outward step connects the two armature windings and the two field windings in series, a small resistance being also thrown in. The second step cuts the resistance out. The third places the armature coils in parallel, but leaves the field coils in series. The fourth and final step places the field coils in parallel, and gives the vehicle its maximum speed. The first step is only used for starting. When the lever is brought to the second, third, and fourth steps, the cab attains speeds of 3, 7, and 9 miles per hour respectively. By the employment of the stepping up and down arrangement the cab is brought under complete control, whilst the reversing mechanism, in addition to a foot-brake arrangement which is fitted, enables stopping and backing operations to be more quickly carried out than would be possible in a horse-drawn vehicle.

The current from the accumulators is made to pass through a switch attached to the foot-brake, so that whenever the foot is applied to the brake the current is disrupted, thus avoiding all possibility of damage to the motor should the cab be brought to a standstill while the current is still on. As another safeguard, the driver of each cab is supplied with a special key-plug, which he carries about with him. This plug is used as a switch, and makes or breaks the battery circuit whenever it is inserted or withdrawn, the obvious advantage being that if the driver leaves his cab, taking the key with him, it is impossible for anyone to tamper with or start the vehicle.

As a means of regulating speed in a self-contained motor-car, actuated by batteries, two methods are at present in vogue. The first is by splitting up the battery into sections by a suitable commutating arrangement, thereby putting the sections either in series or parallel as required. The objection that may be raised to this plan is that the cells may be unequally discharged. A more practical method, and one adopted on the London cabs as explained, is using the battery as a complete unit, and obtaining the various speeds by commutating the coils in the fields and armatures of the motor. It is possible that some method may be adopted by which the motor may be run at constant speed, while the speed variations in the car are obtained by suitable gearing. According to present practice the motor, when starting the vehicle, is running slowly, and therefore in its most inefficient condition. If the constant speed idea were utilised, the motor might be of smaller power, and it could also be run at a higher and more uniform efficiency.

Methods of recharging will have to be seriously considered. There seems no reason why in all our large towns charging centres should not be established. The ordinary cab is stationary a great part of the day, and there seems no valid reason why the charging operation should not be rendered so simple that a cabman of ordinary intelligence could easily perform it. With an "in-and-out" electricity meter placed on the vehicle in a convenient position on the battery circuit, the driver could see at a glance how much energy had been put in and taken out of his battery; therefore, would know when a recharge is required; also, when charging, by reference to the meter he could see when his battery is satisfied. Such a measuring instrument with the small range required need not be an expensive addition. A supply system worked on the penny-in-the-slot principle could easily be arranged. The battery, of course, would not be removed, but would be connected up to the source by suitable flexible mains. Under these conditions the driver could buy his supply of electricity much in the same way as a carman can now buy fodder for his horses.

The form of battery required for driving a self-contained motor-car over common roads may need to be of a different nature to that required in cars running on a permanent way, where the tractive force remains more nearly constant and where there is less jolting and vibration. Possibly some form of mechanically solid cell with a Faure type negative and a Planté type positive element will fulfil the requirements.

As to the probabilities of the self-contained electric motor-car comparing favourably with horse haulage, this will entirely depend upon its economic aspect. However great the convenience of electric haulage, however great its reliability, ease of manipulation, sanitary aspect, and general convenience, the question as to whether it is best or not has still to be satisfactorily answered. In its present experimental stage trustworthy figures of the daily or weekly cost of up-keep cannot be expected. It is only by taking the average expenses incurred during months or years that anything like an accurate estimate can be arrived at. The initial cost and cost of maintenance of the batteries employed will, we believe, be the controlling factor. Whatever turn the idea of electrically-propelled motor-cars may take, it must necessarily always involve the use of some apparatus for storing and giving out electrical energy.

The modern secondary battery leaves very much to be desired, but still there are several very good batteries for this purpose obtainable, and these may serve to tide the electric traction man over the period intervening before the advent of the ideal cell which we all wish to see.

VALVES OF SMALL STEAM MOTORS.

Messrs. Easton, Anderson, and Goolden, the well-known engineers of Erith, have recently effected some important improvements in the arrangement of valves for small steam engines, by which they diminish the clearance in the H.P. cylinder very considerably, and also make the engine more compact. The following drawings show the method of fitting the piston valves and the steam parts.

According to this invention two valves are used, about the same diameter, and which should both be worked by the same eccentric. 13*, in the valve chamber, 12. The valves, 3 and 4, are connected to, and operated by, a single eccentric, or valve gear (not shown). Live steam from the boiler is admitted to the chamber, 9, of the high pressure valve, 3, through a passage, 13, the steam passing into the high pressure cylinder, 1, either at the upper end or at the lower end, governed by the valve faces, 6 and 5, respectively, according to the position of the valves. In the drawings the valves are shown in central position, and closing all the ports in the chambers, 9 and 12, the piston, 1*, of the high pressure cylinder, 1, having just completed its down stroke, and the piston, 2*, of the low pressure cylinder, 2, having completed its up stroke. On the valves moving downwards from the position shown, the ports, 5*, 6*,

Fig. 3.

Fig. 1.

The parts in connection with these valves, and with the respective cylinders are so arranged that one of the valves only distributes the steam to and from the high pressure cylinder, whilst the steam exhausted from the high pressure cylinder to the low pressure cylinder passes through both valves and the exhaust from the low pressure cylinder is controlled by both valves.

Referring to the drawings, Fig. 1 represents in longitudinal vertical section high and low pressure cylinders and their valves, while Fig. 2 is a horizontal section on the line *a b*, Fig. 1, and Fig. 3 is a transverse vertical section on the line *c d*, Figs. 1 and 2. 1 is the high pressure cylinder and 2 the low pressure cylinder, between which cylinders are arranged two valves, 3 and 4, by which the passage of steam to and from the cylinders is controlled. The valves are of the piston type, the high pressure valve, 3, having four collars, or valve faces, 5, 6, 7, and 8, governing four ports, 5*, 6*, 9*, 9**, in the valve chamber, 9. The low pressure valve, 4, has two collars, or valve faces, 10, 11, governing two ports, 12*, 9*, 9**, in the chamber, 9, will be opened and allow the live steam to enter, by the port, 5*, the cylinder, 1, beneath the piston, 1*, whilst the steam in the cylinder, 1, above the piston, 1*, will pass, by the ports, 6*, 7*, and 10*, into the low pressure cylinder, 2, above the piston, 2*. The high pressure piston, 1*, will now make its up stroke under the action of the live steam whilst, by the expansion of the steam from the upper end of the cylinder, 1, acting on the piston, 2*, of the low pressure cylinder, the piston, 2*, will be caused to make its down stroke whilst the steam in the cylinder, 2, below the piston, 2*, will pass through the port, 11*, 12*, in the low pressure valve chamber 12, also through the ports 8*, 9**, in the high pressure valve chamber, 9, into a chamber, 14, communicating with the exhaust passage, 15. On the reverse movement of the valves the port, 6*, is opened to the live steam entering the valve chamber, 9, by the passage, 13, the steam passing through the said port, 6*, into the high pressure cylinder, 1, above the piston, 1*, the steam contained in the cylinder beneath the piston, 1*, passing through the ports, 5*, 8*, and 11*, in the chamber, 9, into the low pressure cylinder, 2, beneath the piston, 2*, whilst the steam contained in the cylinder, 2, above the piston, 2*, passes therefrom through the ports, 10*, 13*, in the valve chamber, 12, and through the ports, 7*, 9*, in the valve chamber, 9, into the chamber, 16, communicating with the exhaust passage, 17.

By the arrangement it is claimed that a free passage for the exhaust steam is provided and compactness is obtained.

FACT AND FICTION.

Fact.

The well-known *Daily Graphic* electric cab, which has been running about the streets now for upwards of six months without accident, broke down recently through the insulation of some of the leads being rubbed off, with the result that a short circuit was set up and there was considerable sparking, until the battery connections were switched out. The cab was at work again within six hours.

Fiction.

Says the *Financial News*:—"The march of the motor-car, which is being watched with such interest by nearly everybody, may be temporarily checked by the awkward accident which happened in Oakley Street, Lambeth. 'Something went wrong with the works,' an explosion followed, the car caught fire, and the bottom of the vehicle was completely destroyed. Happily, there was no passenger within, and the driver escaped without any serious injury; but the incident will probably act as a skid on the progress of the motor-car as a rival to the gondola of London streets."

The *Daily Telegraph* (of course) goes one better. In its own special florid and Salacsque style it says:—"Jehu will rejoice at a misfortune which overtook a motor-cab in Oakley Street, Westminster Bridge Road. It was leisurely going along on the look-out for fares, when it was seen to be emitting smoke and flames. It was pulled up to the side of the road, and half a dozen people tried to put the conflagration out; but as no one understood the internal mechanism, there was nothing to be done except to stand and watch the destruction of the cab. In time the fire burned itself out, after everything that would burn had been destroyed. What was left of the vehicle presented a very sorry appearance, which seemed to cause much amusement to the ordinary cab-drivers, who indulged in a good deal of chaff at the expense of their unfortunate rival."

The *Evening Standard* could not resist the temptation, and delivered itself thus:—"Whilst a motor-car, which plies as an advertisement for the *Daily Graphic*, was proceeding along Oakley Street, Lambeth, an explosion occurred in the works, and the car caught fire, the bottom of the vehicle being completely destroyed. The driver fortunately escaped without serious injury, and luckily there was no passenger inside the car at the time."

And journalists complain that the public does not sufficiently appreciate them!

PIONEERS OF THE FRENCH MOTOR-VEHICLE INDUSTRY.

(*From "La Locomotion Automobile."*)

MM. Panhard et Levassor.

Messrs. Panhard and Levassor were the principal promotors of the petroleum vehicular industry in France; not that other trials had not been made before, which we have not by any means the intention of overlooking, but because they were, we believe, the first to come before the public. It was about 1890 that they made their first carriage, and immediately after they constructed 10 motor-cars to seat two, provided with two cylinders of $1\frac{1}{4}$ H.P. At that time, already so far distant in the memory of automobilists, these builders used the "Daimler" motor, of which they had undertaken the manufacture. They made fixed motors for industrial purposes and lighter motors for carriages, tramways, boats, &c.

From the commencement the form of the car resembled the Victoria, in which the driver's seat is replaced by a box containing the machine. The rear wheels are the driving ones, and the front ones are the steering; the transmission is made by means of a Galle chain, and the change of speed by cogged pinions. The wheels are of wood, and the box placed in the front of the carriage gives a characteristic air to the vehicle, which has varied very little during the last eight years. At the commencement three different speeds were attained—three, six, and ten miles per hour. Added to this also, the price of a car to seat two was then, judging from their catalogue of August, 1891, 3,500 francs.

In October, 1892, the firm Panhard-Levassor constructed four principal types of carriages—dogcart, to seat four; wagonette; break, to seat six; and a carriage to seat two, with or without a little seat at the back. They began at this time to use indiarubber tyres, which gave very good results, but were rather expensive.

About the same time the builders were actively employed in applying the Daimler motor to the propulsion of boats. Since then the public are more in favour of the new mode of locomotion, and this nautical branch of the industry has been a little neglected, although the advantages of it are very considerable.

If the successive improvements of the Panhard-Levassor carriages were to be described it would mean relating all that has been done in the way of wheels, tyres, frames, and especially the distillation of light petroleum. The motor itself has been very little changed. In the primitive Daimler model each piston had a valve opening on the side of the chamber of compression, intended to prevent the back pressure which might have existed at the end of the run, in direct proportion with the capacity of the cylinders. The first modification suppressed that feature.

For a long time the manufacture of motors was confined to those of small power, taking every means of reducing the passive resistance as much as possible. Afterwards motors were used with $2\frac{1}{4}$ H.P., then some were made giving $3\frac{1}{2}$ H.P. But, beyond that, a stoppage occurred on account of the weight of the Daimler motor. A carriage with a Daimler motor giving nearly 4 H.P. was seen in the Paris-Bordeaux race of 1895. That date marked the end of the Daimler, so far as the firm were concerned, and the advent of the Phœnix motor.

It must be remembered that the Phœnix weighs but 200 lbs. per $4\frac{1}{2}$ H.P. (with four cylinders). The two cylinders are parallel instead of being inclined 15°, as with those of the Daimler. The ignition is effected by incandescent tubes. Each cylinder includes a jacket for water, and works on the four-cycle or Otto system in alternate periods.

In the old Daimler carburator the float delivered a constant volume of petroleum, through which passed a current of air to a tap with three openings, which regulated the quantity of hydrocarburated mixture; this method is replaced now by a Phœnix carburator, which is composed of two parts—the regulator, by which a constant level is obtained by a ball-cock which actuates an obturator; and the diffuser, where the carburation is, so to say, made. To effect that, the liquid is drawn up with every stroke of the piston, and goes out by an opening of a few millimetres opposite; this opening has a conical surface intended to break the flow. The coming of the air in contact with the essence so pulverised can, besides, be regulated. As for the mechanism of transmission, it has remained very much the same as it was at the commencement. The movement of the motor-shaft is transmitted by a conical spindle with friction, and the second shaft placed in the rear of the first. Thanks to this progressive traction the motor can be worked without working the second shaft, and the starting is not jerky. Upon the motor-shaft is an intermediary shaft, used in changing speed. It can go at a rate of 31 miles per hour for certain special vehicles. All the vehicles are provided with brakes upon the hubs, and with one ordinary brake acting on the tyre.

The Panhard-Levassor carriage is represented in many aspects. The most characteristic types are too well-known, and many of our readers must have remarked them in the different celebrated races. We give in Figs. 1, 2, 3, and 4 different models of delivery carts, wagonettes, and omnibuses.

Although the motor is always the same it is as well to mention that it is made now with 6, 8, 10, and 12 H.P., allowing reasonable speeds for the heavy carriages to seat six, or the powerful one for goods delivery, and to obtain also higher speeds for a carriage to seat two.

A truck, Fig. 1, provided with a Phœnix motor, is shown, and a small mail-cart, Fig. 2, for the Compagnie du Nord. It may be mentioned on behalf of the first one that they can be constructed now with more room for the goods than the one of which a drawing is here given. Besides, it is easy to understand that the builders have had little leisure to think of the useful part of the industry, when there is so much to be done in private carriages.

Every one realises the active part that the firm Panhard-Levassor has taken in the motor-vehicle displays during the last four years.

Their first public success dates from the competition of the *Petit Journal*, Paris-Rouen, 1894. In the race Paris-Bordeaux-Paris, in June, 1895, the first vehicle that arrived in Paris was the celebrated

Fig. 1.—Goods Lorry.

"No. 6." It gained the second prize, the first only being granted by the regulation of the course to a car to seat four. It did the 738 miles in 48 hours 47 minutes, or at the rate of 15·13 miles per hour. Two other carriages of the same firm took sixth and seventh prizes.

In May, 1896. in the race Bordeaux-Agen, the Panhard-Levassor carriages were classed second and fourth.

In the race Paris-Marseilles, September, 1896, the three first prizes of Class "A" (carriages to seat two, three, and four) were given to the Panhard-Levassor carriages.

In the race Marseilles-Nice-Monte Carlo, January, 1897, Messrs. Prevost, De Knyff, Giraud, were classed respectively third, fourth, and fifth, driving carriages made by this firm.

In July, 1897, Mr. Gilles Hourgiere drove successfully a carriage that was classed in Paris-Dieppe first of the carriages to seat two. This carriage can be taken as a type of cars for races, all the parts not strictly indispensable having been reduced to the most simple form.

Fig. 2.—Post Office Van.

In the recent Marseilles-Nice race the first three winners rode Panhard-Levassor carriages. This long train of success is abundant evidence of the superiority of these vehicles.

In a word, all our readers will still remember the good appearance of the Panhard omnibus during the competition of Les Poids Lourds. It was the only one, with the camion Dietrich, that supported successfully the reputation of petroleum.

This firm, not yet old, has also had its private history. The death of the lamented Mr. Levassor changed the firm into a limited company, with a capital of 5,000,000 francs. Messrs. Panhard, Perron, Clemont, De Knyff, Krebs, &c., are among the directors.

The workshops are always increasing, but are insufficient, and cover now an immense area. They are now completing new workshops, the area of which is about 400 metres carrées.

In conducting their business the firm require a long notice before delivering, and their terms are very high. They intend, it is said, to think seriously about heavy traffic vehicles. Other omnibuses will be built larger than the one at present at work.

Fig. 3.—Waggonette.

The Orleans Railway Company are awaiting a delivery of 12 goods vans, with which experiments will be made for the transport of small parcels. Several business houses now use these cars for delivery. In Paris there are cars belonging to Mackenstein, Demarson-Chetelat, the Louvre, Bon Marche, and the Printemps. With regard to cab competition, they intend to place on the ranks five carriages of different forms—coupé, victoria, landau, station omnibus, &c. These vehicles will be provided with a new Krebs's magnetic traction device. They are also busy with improvements in changing speed gears which are now rather noisy. The firm does not try to attract buyers, and the managing director is not pleased, so it is said, when new customers appear—at least for the present.

Fig. 4.—Omnibus.

Profiting by the experience acquired the new firm will be able to sell to the public at cheaper rates, as the tools are less expensive and the workmen more skilful. In conclusion, the public owe a debt of gratitude to the Panhard firm for appearing first, and for having borne the enormous expenses incurred by experiments and trials.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to The Editor of "The Automotor and Horseless Vehicle Journal," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. King and Co., Limited, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. King and Co., Limited, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

The Automotor and Horseless Vehicle Journal *can be obtained from all* Messrs. W. H. Smith and Son's *bookstalls, and the following Agents:—*

London: Pottle and Sons, 14 and 15, Royal Exchange, E.C.
Wholesale: Brett and Co., 5, Pilgrim Street, Ludgate Hill, E.C.
Birmingham: J. McCann, 37, Union Street.
Manchester: John Heywood, Deansgate.
Newcastle-on-Tyne: C. C. Ross, 35, Side.
Paris: Homère Moreau, 97, Rue Nollet.
Victoria (Australia): Phillips, Ormonde, and Co., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

Most of the back numbers can still be obtained at 6d. per copy, or 7d. per copy post free.

INDEX TO VOL. I

Is Published Free with the October Number.

NOTICE.—A few copies of Volume I, bound complete, can still be supplied at One Guinea net, in consequence of our having purchased some of the numbers out of print, enabling us to make up some more complete sets.

COVERS FOR BINDING VOLUME I

Price 1s. 6*d.*; *Post Free,* 1s. 9*d.*

Can be obtained through the usual Agents, or direct from the Publishers.

Proprietors and Publishers—F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

APRIL 16TH, 1898.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month.

1898.	
April 24 ..	Paris Motocycle Critérium.
May 2, 9, 16, 23	Society of Arts Cantor Lectures—"Electric Traction," by Prof. Carus Wilson.
May 24–27 ..	Self-Propelled Traffic Association (Liverpool Centre) Heavy Vehicle Trials.
May 25 ..	"Concours de Fiacres," Paris. Organised by the Automobile Club of France.
June	International Italian Exhibition of Motor-Vehicles (Turin).
June 10 to 25..	Motor-Vehicle Exhibition, Paris. Automobile Club of France. Sections—(*a*) Automotor vehicles which have given proof of their practical efficiency; (*b*) Industries connected with automobilism; (*c*) Motors adapted for automotors; (*d*) Vehicles adapted for automotors.
June 15 to July 15	International Concours of Automobile Tricycles and Bicycles in connection with the Turin (Italy) Exhibition.
June 25 and 26	Brussels to Spa Race. Organised by the Automobile Club of Belgium.
July 3 to 11 ..	Race from Paris to Amsterdam, under the auspices of the Automobile Club of France.
1899	Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.
1900	Paris International Exhibition—Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

DR. W. LATTEY (Southam, Warwickshire).—We have received your letter and drawings; the latter we have returned. Your idea is ingenious but not new, and in the present state of the law it cannot be practically applied. Article II, sec. 3, of the Regulations of the Local Government Board says:—"The tyre of *each* wheel of the light locomotive shall be *smooth*, and shall, where the same touches the ground, be *flat*." Want of adhesion is only likely to be experienced in very light vehicles when ascending an abnormally steep and greasy gradient. If slipping occurs it will best be prevented by trailing the "devil," or by the time-honoured zigzag course. A spiked wheel which you suggest (by the way, it reminds us of a road scarifier), would not be economically advantageous, as it would be so rarely used and would mean extra power in carting about a mass of metal.

LUBRICANT.—Do not use the oil in question without a guarantee from the vendors that it is pure, unadulterated mineral oil. Put no faith in fancy names of oils. Specify the fire point. If you send us a sample we will tell you. On no account use vegetable or animal oils.

JEHU.—We could not say unless we made an inspection. Consult a good engineer who makes this work a speciality.

W. SMITH.—Liquid fuel was first applied to ocean-going steamers, so far as we know, in Messrs. Suart's oil-tank steamer, "Baku Standard." The arrangement was not altogether successful, as it has not been repeated.

MESSRS. HITCHEN AND CO., Stockport.—Why not communicate with Mr. Brown direct? We understand the boiler to be a vertical multi-tubular. Unfortunately builders of successful motor-vehicles display a perfectly natural but inconvenient reticence as regards the publication of details which may have cost much time and money to perfect.

ELECTRICAL STUDENT.—According to the best and most recent practice the weight of secondary or storage cells as applied to vehicles such as cabs, &c., is about 430 to 450 lbs. per E.H.P., or, in other words, storage cells weigh per H.P. about as much as the heaviest types of marine machinery; so there is plenty of room for improvement.

E. W. (Winchester).—No. The English agents are so full of orders that they cannot possibly supply you with a car. Try the Daimler Company, or Roots and Venables.

OMNIBUS (Gloucester Road).—It is not a Panhard and Levassor. The motor is a Daimler, although not built by the English Company. The omnibus had a trial trip to Ealing and back on Monday, the 4th inst., we understand with satisfactory results to those interested.

THE PERFORMANCES OF THE POST OFFICE MOTOR MAIL VANS.

THE *St. Martin's le Grand*, the Post Office organ, contains in its April number an article on motor mail vans, which, while readable and interesting enough in its way, is yet singularly deficient in those details regarding consumption, speed, power, and endurance, cost of maintenance, &c., without which it is difficult, if not impossible, to form any accurate opinion of the merits of the various vehicles. It seems that the first motor-van was supplied by the British Motor Syndicate, of Holborn Viaduct, the motor being a "Daimler." Its daily journey was 27½ miles, carrying 6 to 8 cwt. of mails. It was allowed 23 minutes for each journey between the G.P.O. and the South-Western District P.O. We are told "it not only kept better time, but as a rule reached its destination at each end before it was due." Another trial of the van on the route to Kingston-on-Thames was also successful, and then we come to this significant remark: "This van has not since been employed for mail services."

The "Lifu" steam van, introduced to the Post Office by Messrs. Julius Harvey and Co., was tried on the London and Redhill route. It started on its service on December 16th, and ran with great success till January 26th, when it was taken off the road for a general overhaul, taking up the service again on February 14th, and we learn "was even more successful than during the first trial, *performing every journey without mishap and always within the time allowed.* On some nights it carried as much as 16 cwt. of mails, and could easily have carried a ton." The official view seems to be thus expressed:—"The steam motor-van would, therefore, appear to combine strength with speed, and in these respects there is no doubt that at present it holds the field."

We may remark that this opinion merely confirms the results of Les Poids Lourds trials, which, as our readers know, we have so fully discussed in our columns.

The third motor-van was one in which the energy was derived from a battery of secondary cells; in other words, it was what is termed an electrical motor-van, and was supplied by the Electrical Cab Company, of Lambeth. From our own private information we know that this van, for reasons which need not be stated, did not, and could hardly be expected to, run with uniform success, the official verdict being that "it proved, *on the whole*, a great success"—a very qualified meed of approbation.

There are various points in the design of this vehicle which seem to indicate, to say the least, extreme crudity of design. We are, however, sure that an electric motor-van for city and surburban service can be produced which will abundantly satisfy the Post Office officials. But such a vehicle would differ materially from the Electrical Cab Company's design.

In an official organ one does not expect to find either reasons, deductions, or conclusions, and the article from which we have quoted is no exception to this rule of official reticence. We have, however, said enough to enable those who are familiar with the three types of motors tried to form a pretty accurate conclusion of their own. For official work, as distinct from ordinary commercial or private work, a delay means a penalty of some kind. Absolute certainty of manipulation and absolute endurance are absolute essentials if commercial success is to be expected. From this point of view, light petroleum oil-motors, such as the Daimler, evidently do not satisfy official requirements. Electrically-propelled vehicles, if of good design, *ought* to. But so far the steam motor is superior to either the internal combustion motor or to the electric motor, and this seems to be the official view, inasmuch as the Lifu was accorded two distinct trials as against one each for the other vehicles. We have some reason to think, however, that the official opinion is that, notwithstanding the not altogether satisfactory performances of the Electrical Cab Company's vehicle, enough was learned to satisfy the authorities that for traffic in the metropolis an electric motor-vehicle is the more suitable; while for suburban and country work the advantages are in favour of the steam van.

The article concludes with the following truly official pronouncement:—"The trials are over for the present, but further developments will, no doubt, take place shortly. To what extent, however, motor-vans will supersede the ordinary mail vans time alone will prove." We may remark that time is not an important factor in solving the problems of mechanical traction, but commercial and official enterprise, scientific mechanical knowledge, and lastly, but not least, capital are. If the Post Office does not yet save the public money by carrying the mails in motor-vehicles—if the London County Council, with a conservative tendency worthy of the best or worst days of the City Corporation and the Metropolitan Board of Works still carts about the municipal street refuse in horse-drawn vehicles, and endeavours feebly enough to extinguish our all too frequently recurring City fires by obsolete inefficient steam-squirts, also drawn by horses, the public must not conclude that motor mail vans and motor steam fire-engines are not to be had. On the contrary, the French trials and the trials carried out by their own officials, and to which we have referred, have profoundly convinced the postal authorities that mechanical traction will enable a great reduction to be made in the cost of carriage of mails and parcels; and when the present contracts for horsed mail-vans expire makers of motor-vehicles will be given every opportunity of tendering upon what we believe will be liberal terms. Whether the new London County Council will emulate the Post Office and endeavour to lessen the present very heavy rates by the employment of motor dust and water carts and motor fire-engines we, of course, do not know, but sufficient evidence is before the public to show, as in the case of Chiswick, that for all municipal purposes horse haulage can be superseded by mechanical traction with a very considerable saving of the ratepayers' money. We may then expect the more intelligent and progressive members of the Council to press this matter if on no other grounds but those of economy of working, to say nothing of greater efficiency.

THE AUTOMOBILE CLUB OF GREAT BRITAIN

Among the names of the many distinguished persons who have recently joined this Club we observe that of Mr. Alfred Suart. This gentleman is a large petroleum tank steamship owner, and was one of the first to build and own this type of vessel. By his enterprise and energy he made this new trade a peculiarly British one. Mr. Suart is well known and highly respected not only in London but in New York, Paris, Vienna, and in the Caucasus, in fact in nearly every centre of the oil trade; while his house-flag, a flying fox, can be seen in nearly every sea. With such members as Mr. Suart, Prof. Boverton Redwood, and others, the Automobile Club will, in addition to its ordinary functions, be able to exercise a powerful influence in preventing any hysterical petroleum legislation such as that we are threatened with.

THE LANCASHIRE STEAM MOTOR COMPANY'S HEAVY TRAFFIC VEHICLE.

As will be seen from the interesting account of the trials of this vehicle which we publish elsewhere in this issue, the difficulties in design and construction imposed by the Locomotives on Highways Act have been surmounted in a very clever and mechanical way. Everyone will congratulate the builders and their manager, Mr. Spurrier, on the great success they have attained. We—and we are sure our readers also—are particularly pleased with this result, as it forms such a curious and unanswerable reply to the very pessimistic utterances of various speakers at the recent meetings of the Liverpool Centre of the Self-Propelled Traffic Association. We have been assured by "authorities" that the construction of vehicles intended for heavy traffic was not at present a practical possibility. We have been urged to stick to wooden wheels, wooden frames, impossible boilers, and to discard water tubes, liquid fuel, channel steel, and every other adjunct of modern scientific engineering. We have been told that if you get your wagon it will slip through insufficient adhesion, and not a few London and Liverpool engineers have metaphorically wrung their heads and hands and bewailed the difficulties in the design of vehicles intended for heavy traffic. In the meantime the Lancashire Steam Motor Company have practically solved the problem, and that in the only way it can be solved—viz., by taking full advantage of up-to-date engineering knowledge as exemplified in torpedo-boat practice. We have every respect for those who design and build machinery, such as locomotives, traction-engines, and mercantile marine machinery, in which weight is really of no consequence, or rather an advantage, and which are distinctly slow-speed motors. The ideas governing such designs are no doubt all very well, but they will never enable one to design a practical motor-vehicle intended for heavy traffic. We are the more pleased with the success of the Lancashire Steam Motor Company for a personal motive, which we may be pardoned for mentioning. In the paper "On Some Points in the Design of Motor-Vehicles intended for Heavy Traffic," read before the Liverpool Centre of the Self-Propelled Traffic Association by the Technical Editor of The Automotor, several features in design were advocated which it had evidently been previously decided to adopt in the present vehicle. Thus steel frames, 5-inch tyres, high-pressure steam, and high revs. per minute were advocated in the paper in question, as was the use of aluminium bronze for parts which are usually cast in iron. There is no question but that it is by an intelligent combination of these features that the Lancashire Steam Motor Company have achieved their success, and we cordially congratulate them.

THE CONGESTION OF THE TRAFFIC IN THE CITY.

In many respects we are a singularly illogical people, and usually welcome a public benefit by heartily damning it. Our streets are often impassable through the congestion of traffic. Horse-drawn vehicles are so long that they occupy, as compared with motor-vehicles, practically twice the space. Any tradesman or other citizen who employs automotor vehicles instead of horse-drawn ones is conferring a distinct boon upon the community, because he is doing his part in lessening the congestion, to say nothing of the saving in wear and tear of the street. Yet, do we welcome and encourage him? Not a bit. Magistrates and police, with a natural obtuseness, seem to make rather a dead set against all vehicles not drawn by horses. As our readers are aware, in more than one provincial town this action has been so pronounced as to savour of actual illegality. Of late the London police have, with a singular lack of intelligence, been endeavouring to exclude cyclists from the City, and, of course, recourse was had to that good old remedy the "bye-law." It does not occur to the average City Father that he may be ever called upon to satisfy a High Court as to the legality of a bye-law that he and his colleagues in their wisdom may impose upon a long-suffering community. However, the attempt has failed, the Court of Common Council, at their last meeting, having definitely agreed to adopt the report of the Police Committee to the effect that no new bye-laws were necessary. Some of the City magistrates, nevertheless, entertain pronounced opinions upon the wickedness of the tradesman's tricycle. In a case which came before Mr. Alderman Bell at the City Court lately a young man was charged with riding the tricycle to the common danger. He averred that he rang his bell, and further pointed out that the machine was plain-geared, and that any pace beyond what he could do on his legs was impossible—a clear statement of fact, perfectly intelligible to anyone who understands machines. The young man also stated that the machine was heavily laden. Notwithstanding these statements, against which no rebutting evidence was brought, the Alderman remarked that tricycles were a "constant source of danger," and imposed the outrageous sentence of seven days' imprisonment in default of payment of a fine and costs. To contend that a tricycle is a source of danger, whereby implying that a hansom cab is not, is too absurd.

WHY NOT TRY MOTOR-VEHICLES?

It is well known that in the Midlands the greatest dissatisfaction prevails among manufacturers of iron goods with the heavy rates that the railway companies charge for transport. Notwithstanding all the classification and revision of rates that has been effected in recent years, the fact remains that the rates of freight are so high as to seriously handicap the manufacturers, who find that they are losing their hold on many foreign markets, especially in the East. In order to avoid these heavy charges, a few of the leading firms have removed their businesses to places nearer the shipping centres. Thus some firms have gone to Cardiff, and other places in that neighbourhood, where coal and iron are cheap, and where smith and forge work can be done just as well as in the Midlands, and without incurring the heavy charges for shipment. As we have pointed out before, the railway companies cannot materially reduce these latter. They have very expensive roadways and rolling stock to maintain, and, in fact, supply a needlessly expensive means—as far as goods are concerned—of transport. It is obviously absurd to carry such things as rods, bars, nails, galvanised iron, and such like goods on an expensive railway track. Yet a goods train from Sheffield or Birmingham is sent through to Cardiff or Liverpool with the same care and cost as an express passenger train. Really, the solution lies in one of two ways—either the seat of the Midland manufactures must be transferred to the seaports, or the goods must be carried by less costly means. The former is possible, but difficult of realisation. Of the latter, canals, light railways, and motor-vehicles using the ordinary roads suggest themselves. The canals are mostly in the hands of the railway companies, thanks to the unwise and impolitic railway legislation of the past, and so are out of the question. Light railways are also, as they would not, according to our way of doing things, materially reduce the expense of transport. If sanctioned at all, in face of the powerful railway interest in the House of Commons, the capital would, it is certain, be indirectly found by the companies, who would, in any case, manage to exert a controlling influence. Motor-vehicles, owned by the manufacturers, offer the cheapest and easiest solution of the problem. There is nothing whatever to prevent a manufacturer from being his own carrier, and before taking a step so serious as removing to another district, and one so likely to be disastrous to the prosperity of many inland towns, we would suggest that a trial should be made of transporting merchandise by motor-vehicles. True, the roads would have to be put in better order to enable them to carry the traffic, but local bodies would cheerfully undertake this rather than a lucrative industry should leave their district. In a short article on this subject, *The Engineer* says:—"It is becoming increasingly plain that the future of the British iron trade will have to be sought for round the coasts of this country rather than, as hitherto to a considerable extent applied, in the interior. The capitalists who have in their hands by far the largest output of manufactured iron of any part of the United Kingdom—we refer to the iron-masters of Staffordshire and East Worcestershire—tired of useless contention with the railway companies, are just now turning their gaze with growing definiteness to the seaboard. The transplanting of works, with their accompanying equipment, heavy plant, and machinery, is no easy matter. It is a step not to be undertaken without grave consideration. If, however, the rising race of Midland rolled iron producers are to preserve their industry at all, and to add to the fortunes which their fathers have made for them, no alternative seems to be left to them. The latest event which is making their existing condition rapidly untenable has been the entry of South Wales and Cheshire into the common sheet-iron and galvanising sheet business. Robbed of this branch, the Black Country loses one of its most important sources of activity, and unless the present works owners are to find themselves stranded, they must, it is clear, follow the trade to the coast. There, and there alone, it would appear, the question of burdensome railway rates ceases to trouble. But one final effort is to be made to prevent migration wholesale. The mayors of five of the leading Staffordshire towns, headed by Wolverhampton, have united in a representation to the three leading railway companies serving the Midlands—the London and North Western, the Great Western, and Midland—urging them to reduce the rates without a moment's longer delay on raw and manufactured iron. Unless a substantial reduction immediately takes place, nothing, it is urged, can prevent the extinction of the sheet-iron trade. The railway managers are invited to meet the traders of the district in conference, and the most earnest consideration of carriers is asked to the position. The situation of the traders is the worse, since, of course, the railway companies continue the control of the canals which they have obtained, and thus not only are makers saddled with rates by rail, which are now clearly proving unsupportable, but they are denied adequate facilities for water carriage."

We say, again, why not try motor-vehicles? We can assure the traders that the forthcoming trials next month in Liverpool will show that vehicles can be produced that will answer all ordinary requirements. We do not say that armour plates and propeller shafting can be transported by road *just yet*, but goods up to 5-ton parcels can. Here, then, is a splendid chance for an enterprising capitalist—the establishment of a line of motor-vehicles from the Midland manufacturing towns to the coast.

THE FLASH POINT OF PETROLEUM.

The Select Committee on Petroleum met at the House of Commons on the 23rd ult. to elect a chairman (in the room of the late Mr. A. J. Mundella), and to decide on the course of procedure. Mr. Jesse Collings, the Under-Secretary of the Home Office, was chosen as chairman, and it was decided to take the evidence of Colonel Sir V. D. Majendie, the Chief Inspector of Explosives, at the first meeting of the Committee on the 25th. On that day that gentleman attended and was examined. He suggests that, instead of raising the flash-point of American explosive oil, lamps should be regulated—an opinion in which we heartily concur. We discussed the question in our issue for January, and are pleased to see our opinions endorsed by such a distinguished authority as Colonel Majendie. The Government are not likely to introduce legislation on the subject, because, as we have pointed out, there is no danger in using ordinary petroleum providing, as is usually the case, ordinary common sense is used a'so. The accidents that have occurred are, in the vast majority of cases, due to the dense and impenetrable ignorance of the lower classes. With our common habit of beginning at the wrong end, we look to legislation to protect us when a few common-sense lectures in the Board schools would do more than any Act of Parliament to ensure the proper handling of petroleum. We would urge upon all automobilists the duty of resisting this senseless agitation against low-flash oil, because, if those who are seeking to impose a high test succeed in their object, it will mean the imposition of greater restrictions in the sale of the light oils such as are used in the Daimler, Panhard, Peugeot, Benz, and Beeston (De Dion) motors. It will also mean placing greater power in the hands of the local authority, who will, of course, have power to make "bye-laws" at its own sweet will and pleasure. Shareholders in motor companies which use what is usually termed "light oil" in their motors should exert all their influence to combat this agitation, as, should petroleum legislation ensue, it will become a matter of extreme difficulty to run a light-oil motor in many districts.

A MOTOR OMNIBUS.

A new omnibus, which, we understand, is intended for suburban traffic, has lately been tried in the western districts of London. This vehicle, as will be seen from the above illustration, is somewhat similar to the familiar Continental diligence. It is very well built and not unpleasing in appearance, suitably furnished for the comfort of passengers, of which it will accommodate about 20. The motor mechanism is of the Daimler type and consists of two vertically-inclined engines, which give off apparently between 8 and 10 B.H.P. The transmission gear has been somewhat modified from that which is used in the ordinary Daimler vehicles, and is altogether of a stronger and more substantial build. We understand that this vehicle has been directly imported from the Continent on behalf of the British Motor Syndicate.

The American Petroleum Oil Trade.—It is believed in many quarters that the agitation against the use of low flash-point oils in this country is responsible for the decreased shipments of mineral oil from America during the past year. The total exports were valued at £10,925,670 in 1897, as compared with £11,519,583 in 1896. Of this amount the United Kingdom took £2,389,195 as against £2,760,699 in the previous year—a decrease of £371,504. The exports to Germany also show a similar falling off, but an increased trade has been done with France and China.

Royalty and Automobilism.—The King of the Belgians has become the happy possessor of a motor-vehicle, a Panhard we believe, and H.R.H. the Prince of Wales is manifesting a keen desire to employ the new means of locomotion but is not quite decided as to the type.

Specifications Published.

THE following is a List of Specifications recently published, and obtainable at the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform charge of 8*d*. per copy. Owing to the enormous pressure upon our columns it has been found impossible to deal in any other form with the accumulation of patents now being taken out in connection with automobilism. As far as possible, a selection for special mention is made by the Editor from the more prominent inventions:—

Applied for during 1896.

28,514. T. TOMLINSON, 128, Stephen's Green, Dublin. Internal combustion and compressed-air engines.
29,062. J. FAVETS, 103, Hatton Garden, London. Driving gear.
29,486. BOULT (P. A. Darrac), 42, Boul. Bonne Nouvelle, Paris. Road-vehicles and motor mechanism.
29,578. F. BRYAN, 87, Wellesley Road, Gunnersbury, London. Combined internal combustion and compressed gas or air engines.
29,854. E. C. L'HOMME, Central Rouen, Lower Seine, France. Explosion-engines or motors.
30,010. W. G. POTTER, 36, Durand Gardens, Clapham Road, London. Engines actuated by oil, petroleum spirit, or other gas-generating liquids.
29,799. F. J. GIBBS and W. WRIGHT, 70, Lower Hurst Street, Birmingham. Frames.
29,933. The Hon. R. T. D. BROUGHAM and W. C. BERSEY, 22A, Dorset Street, Portman Square, London. Controlling apparatus for electrically-propelled vehicles.

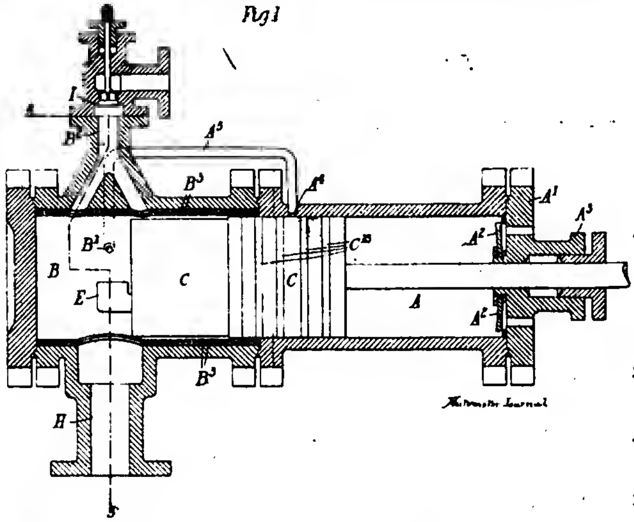
736. Explosion Engines. Montague Herbert Churchill Shann and Richard Ernest Churchill Shann, Westfield, Bromley, Kent. January 11th, 1897.

Relates to explosion engines, in which the fuel is supplied in the form of oil adapted to be vaporised in the cylinder. A cylinder is employed closed at both ends, the end which would usually with engines of this description be open being supplied with atmospheric valves preferably in the cover, so that as the piston travels on its

Fig 1

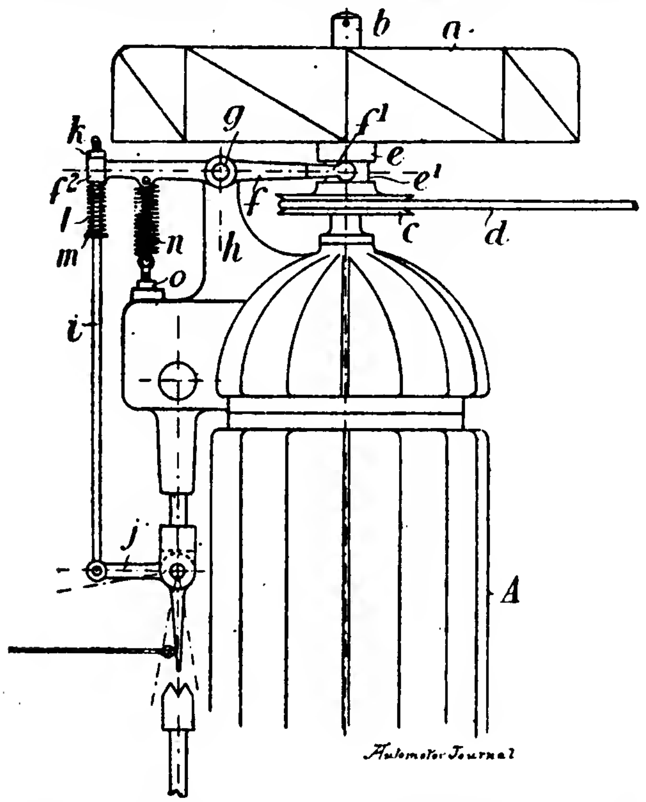


inward stroke atmospheric air will be sucked into the cylinder. The piston is hollow and is provided with valves at its forward or outer end, so that the air sucked into the cylinder upon the inward stroke will be compressed inside the piston upon the outward stroke. The back of the cylinder is employed as the combustion or explosion chamber, and the air from the interior of the piston passes into this space by means of a valve, and impinges upon the oil which enters the cylinder through the cylinder wall or back end or cover, thus spraying or vaporising it, and mixing the air and vapour so as to form an explosive mixture. The valve is adapted to be operated by a movable weight or pendulum inside the piston, arranged so as to obtain advantage of leverage whereby it will have sufficient power to open the valve against the pressure of the air, notwithstanding that the weight itself is a comparatively light one. To facilitate the opening of the valve there is a port or channel in the wall of the cylinder opening into a passage to the interior of the piston at a certain portion of the stroke, which would have the effect of approximately equalising the pressure between that at the back of the piston and the same side of the valve. This pressure would be somewhat less than that in the inside of the piston, so that when the valve was opened the pressure from the interior would rush through to the cylinder behind the valve, impinging upon the oil as already described, and raising that pressure to the maximum before the explosion. The difference between the two pressures being thus relatively slight no great power is required to open the valve.

In the piston is also another valve, which would serve to prevent the access of the pressure from the back of the cylinder to the underside of the former valve excepting when that was desirable, in which case it would be effected by means of the bye-pass. The object of this second valve is to allow the excess of pressure at the inside of the piston to reach the back of the piston when both valves are open.

6,753. Governing Steam Engines, Explosion Motors, and the Like. Frederick Richard Simms, Amberley House, 12, Norfolk Street, Strand, London. March 15th, 1897.

Relates to novel means for governing steam-engines, explosion motors, and the like. Instead of employing a centrifugal device actuated by the crank-shaft of the engine or motor, a fan is so mounted on a spindle, driven from the engine or motor, that it revolves with the said spindle, but is at the same time free to move



axially on the same. The boss of the fan is grooved, and one end of a lever, which controls the admission of steam, vapour, or air to the engine or motor, or the exhaust of the said engine or motor, engages in the said groove. The lever is provided with a spring, the tension of which may be adjustable, and which exactly counterbalances the tendency of the fan to move axially on the spindle when the latter is revolving at normal velocity. With this arrangement, when the velocity of the spindle rises above or falls below the normal, the fan moves axially on the spindle, thus regulating the supply of steam, vapour, or air to the engine or motor, or the exhaust of the same, through the medium of the lever.

567. Motor Road Vehicles. Louis Antoine Jules Tony Krieger, 168, Boulevard Malesherbes, Paris. January 8th, 1897.

Relates to improvements on Letters Patent 24,941 of 1896. The present invention relates, in the first place, to an improvement in the means for operating the steering apparatus, the object in view

FIG. 1.

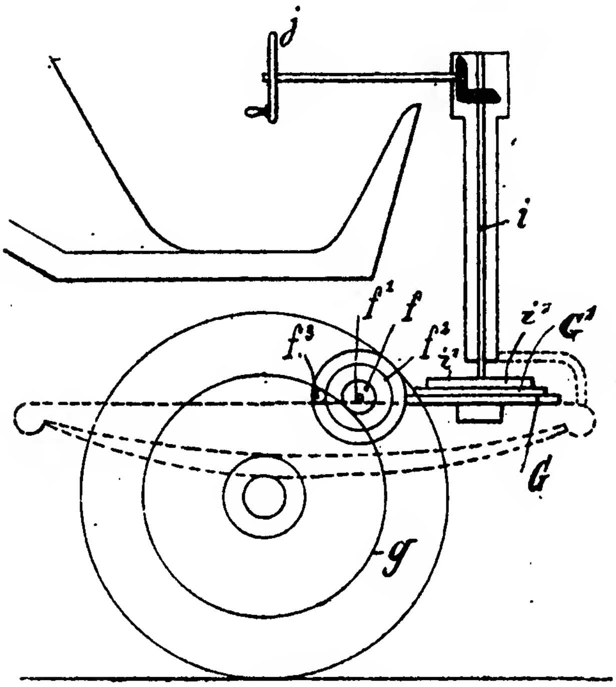


FIG. 2.

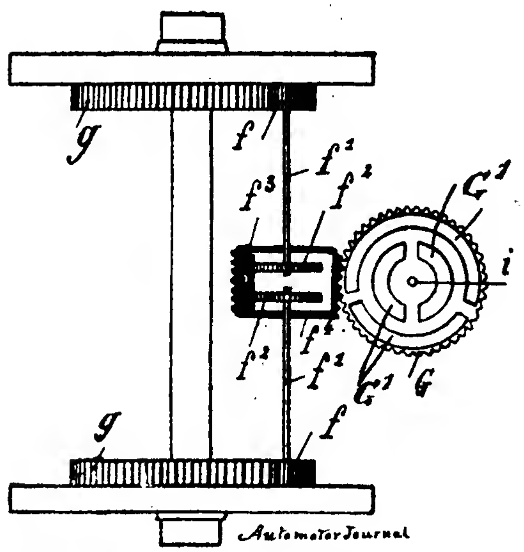


being to neutralise all action of the rear carriage upon the steering of the fore carriage; and, secondly, to the application of the invention to the case where the wheels of the fore carriage are mounted on pivots.

Figs. 1 and 2 thereof are respectively an elevation and a plan illustrating the improvement in the means for operating the steering apparatus. The pinions, *f*, which gear into the toothed wheels, *g*, rigidly fixed to the front wheels, are keyed on independent shafts, f^1, carrying at their other ends two small toothed wheels, f^2, of equal size. The latter gear into a long pinion, f^3, or into two pinions keyed on the same axle. The journals of this pinion or of this axle are carried by a box, f^4, which is provided externally with a worm, and revolves idly on the shafts, f^1. The worm gears into the plate, G, carrying the contact pieces, G^1, of the steering apparatus. If the ratios of the gears are suitably chosen, any difference in the speeds of the two driving-wheels will cause the plate, G, to turn, and the latter will be able to turn through an angle equal to the angle which the driver will have imparted to the handle. The spindle, *i*, carrying the rubbing contacts, i^1, is mounted to rotate in a suitable position, fixed in relation to the fore carriage, and it moves with the latter. It is provided at its upper part with two bevel pinions, that are driven by a horizontal shaft ending in a hand-wheel, *j*, situated in a vertical plane. The whole is supported in place by means of a tube that encases the spindle, *i*, and is fixed to the fore carriage.

In steering, instead of short circuiting the armature of one of the motors, the excitation of the corresponding field magnet may be increased either by increasing the number of the convolutions of its winding, or by applying an auxiliary excitation to its circuit. The arrangement of the steering apparatus is not altered in such cases, except that the field magnet circuits, and not the armature circuits, are connected to the apparatus.

A modified arrangement is described, in which the electrical apparatus may be applied not only to a fore carriage having a king-bolt, but also in those cases where the driving wheels are mounted on pivots.

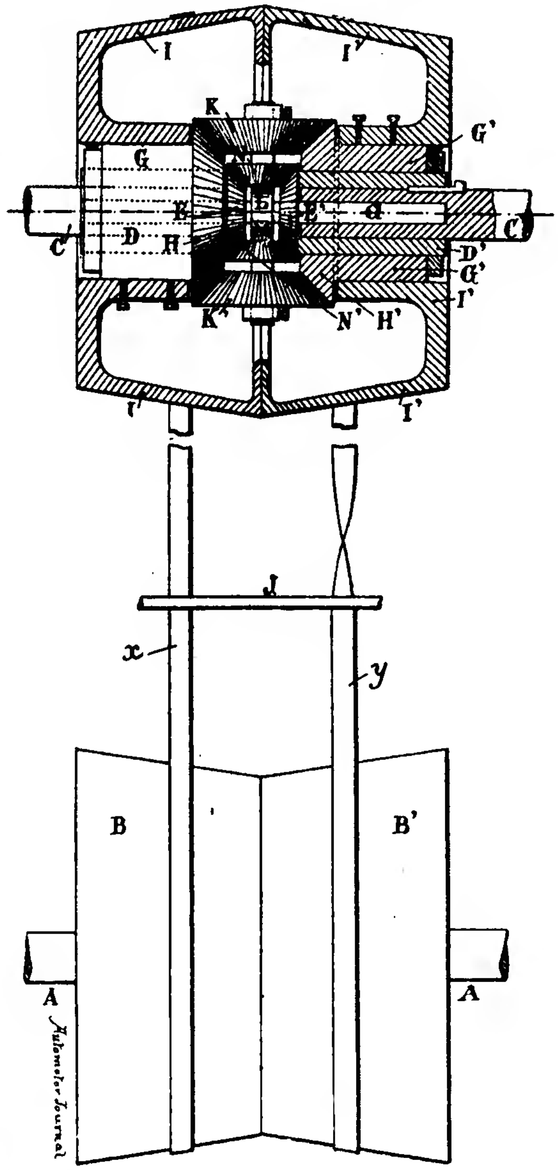
5,802. Differential Motion-transmitting Gear. Count Albert de Dion, Georges Bouton, and Frederic Chaplet, all of 12, Rue Ernest, Puteaux (Seine), France. March 4th, 1897.

On the crank-shaft, A, of the motor-engine two cone or bevel pulleys, B B^1, are keyed with their smaller ends adjacent or facing each other. The axle is in two parts, C C^1, connected together by an axial pin or pivot, *a*, entering axial recesses in the two parts of the said axle. On the adjacent ends of the two parts of the divided axle are rigidly-mounted bevel wheels, E E^1, and mounted loosely on the sleeves or bosses, D D^1, of these wheels are two other bevel wheels, H H^1, and on the bosses, G G^1, of these last-mentioned bevel wheels cone pulleys, I I^1, are mounted and secured by screws, the slope of which last-mentioned pulleys inclines in a direction opposite to that of the inclination of the pulleys, B B^1, carried on the motor-shaft. The cone pulleys, B B^1, are arranged opposite those, I I^1, on the axle of the vehicle, and passing round one of these pairs of cone pulleys is an open belt, *x*, whilst passing round the other pair of these pulleys is a crossed belt, *y*, so that the two pulleys, I I, on the axle, C C^1, of the vehicle are caused to revolve in opposite directions. In consequence of the respective pulleys sloping in inverse directions, variable rates of speed within the limits can be imparted to the two pulleys, and to the bevel wheels to which they are fixed, by shifting the straps or belts on the said pulleys by means of any suitable strap shifter, J, so as to move both straps or belts simultaneously.

Gearing with the bevel wheels, H H^1, are bevel wheels, K K^1, which are loose on a shaft or spindle, L, arranged transverse to the axis of the axle of the vehicle or driven shaft, and provided in its centre with an eye, M, through which the pin or pivot, *a*, connecting the two parts of the said axle or shaft is passed. On this transverse shaft or spindle, L, are also, loosely mounted, two equal pinions, N N^1, gearing with the bevel wheels, E E^1. By adjusting the position of the driving straps, *x*, *y*, on the conical drums or pulleys, I I^1, by means of the strap shifter, J, the said pulleys can all be caused to rotate at the same speed.

As the said drums or pulleys on the driven axle or shaft revolve in opposite directions, together with the bevel wheels, H H^1, keyed thereto, it follows that these wheels cause the wheels, K K^1, which are loose on the shaft, L, simply turn about their axes, the axle, C C^1, of the vehicle or the like remaining stationary, although the motor-engine is in operation at its normal rate of speed.

If the driving-straps be shifted so as to cause the pulleys, I I^1, on the two portions of the divided axle or shaft to rotate at different speeds, the wheels, K K^1, loose on the transverse shaft or spindle, L, will be caused to start a planetary motion about the pin or pivot, *a*, and carry with them the said transverse shaft, L. By this rotary motion of the shaft, L, in a plane perpendicular to the axis of the pin or pivot, *a*, the pinions, N N^1, which are loose on the said shaft, will act as a rigid key between the teeth of the wheels, E E^1, keyed on the axle, and will thus compel the said wheels to turn about their



axes, and with them the axle of the vehicle, and, consequently, the vehicle itself. If from any cause the resistance of one of the wheels should differ from the resistance sustained by the other wheel, this inequality of strains will simply cause the loose pinions, N N^1, to turn upon the said spindle without in the least interfering with the general motion of the conveyance.

The Automobile Club of France.—*Truth* says this club is about to move from the Place de l'Opéra to the Place de la Concorde. It has arranged to hire there one of the finest houses in Paris, that left to the Pope by the late Marquise de Plessis Bellière for a Nunciature. It was sold by auction for nearly £80,000. The internal decorations of this house are by the great artists of the eighteenth century. The walls and ceilings of a small salon were painted by Fragonard.

LAW REPORTS.

The Capsize of a Motor-Vehicle.—The record was closed in the Hamilton Sheriff Court on Friday, the 18th ult., in the action by James B. Struthers, clothier, Larkhall, against the Scottish Motor Omnibus and Car Company (Limited) for £2,000 for personal injuries. The averment is that in December, on the way from Larkhall to Hamilton, while pursuer was on one of the defender's motor-cars, it swerved and capsized, the pursuer being thrown violently on the road, and sustaining severe injuries. The defence is a denial, and that the damages are excessive. They tender £250. The case has since been settled on terms not made public.

Is Acetylene Gas Dangerous?—BOND AND COOPER *v.* THE MIDLAND CYCLE AND MOTOR-CAR EXHIBITION COMPANY.—This case was heard in the Nisi Prius Court, Birmingham, before Mr. Justice Kennedy, on the 23rd and 24th ult. The plaintiffs are cycle lamp manufacturers, of Handsworth, Birmingham, and brought this action against the Midland Cycle and Motor-Car Exhibition Company (Limited), to recover damages for breach of contract. The plaintiffs' case was that they entered into a contract with defendants on the occasion of the cycle exhibition at Bingley Hall to rent a stall for the purpose of exhibiting acetylene lamps. After using the stall for a couple of days the defendants requested them to remove the lamps on the ground that they were dangerous. Expert evidence was called, from which it was gathered that acetylene was not dangerous except from contact with water or when under exceptional pressure. Plaintiffs were awarded £15 damages, the jury holding that acetylene gas under such conditions was not dangerous.

TENTING'S PETROL OMNIBUS.

FOR many of the particulars relating to this petrol motor-omnibus, which is in successful operation between Nantes and Velheuil, we are indebted to our esteemed contemporary *La Locomotion Automobile.* This omnibus (*see* Fig. 1) weighs, when filled with 18 passengers, 6 tons. It presents several advantageous points, to which attention may usefully be drawn. The motor, with its system of pipes, transmission, and accessories, is placed in front of the vehicle. It consists of four cylinders, each of 140 mm. diameter by 220 mm. stroke, coupled direct to the crankshaft. This arrangement permits of an impulse at each semi-revolution of the shaft, and also tends to minimise vibration. The cylinders are provided with jackets, in which a measured circulation of water, stored in a box in the car, allows the lessening of the temperature of the cylinders. The working by the hot water system has given the best results, and the average consumption has not exceeded, so it is said, 250 grammes of oil, at the rate of 680 grammes of gasoline per H.P. per hour.

In the omnibus the motor attains to 16 H.P., or 12 poncelets. The ignition of the mixture of oil, gas, and air may be effected either by means of electricity or by an incandescent tube; and the essence, enclosed in a reservoir at the back, feeds the carbonator at a constant level, and suffices for a run of six hours without stopping. The escape-valve, shown on the drawing, is placed on the roof of the vehicle, so as to avoid all unpleasant smells. Mr. Tenting, satisfied with the results he has obtained with all his automotors by his system of transmission by friction, has retained it in this omnibus, and we understand the working is extremely well.

By manipulating one lever only the motor can be set in motion without jerking, and two speed gear permit of changing the speed at will, according to the winding of the road. The system of steering is specially remarkable by reason of the reliability of its action and the security it offers. Instead of steering wheels being placed in the ordinary way, a vertical support is bent in the form of C, in such a way that the axle in the plane into which the wheel turns is connected with the point of support taken on the ground by this wheel. An absolute firmness is thus obtained at all speeds, and irregularity in steering is thus rendered quite impossible.

FIG. 1.—TENTING'S OMNIBUS.

The mechanism is controlled by very powerful breaks, one of which, with a collar and a wheel and axle fitted on a box, of the differential motion, is worked by means of a pedal placed at the foot of the conductor.

The Tenting omnibus has already made numerous trials, which have been of the most satisfactory nature. In one of these trials, during the winter, it carried 22 people, conductor included, through muddy and sticky roads, at a speed of 20 to 30 kilometres per hour (12 to 18 miles per hour), and the hills were ascended with little difficulty.

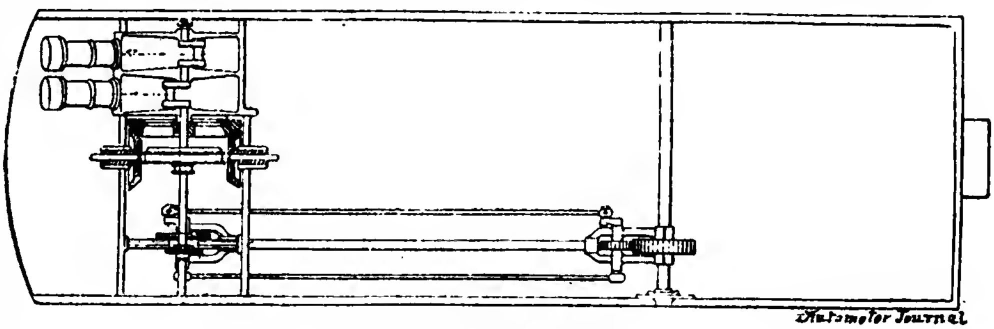


FIG. 2.—TENTING'S OMNIBUS.

It must be added that the tractive effort (and, accordingly, the consumption of petroleum) is regulated by the number of cylinders required. The entrance of carburetted air into one or the other of its cylinders is prevented by simply closing a cock. The Tenting omnibus seems well designed in every detail, and to be capable of rendering very good service—the more so, as the consumption of petroleum is very moderate. It would have been desirable that this vehicle had taken part in the last trials of Les Poids Lourds, where it would certainly have demonstrated its value in competition with the Panhard omnibus; but it is to be hoped that this is only deferred, and that Mr. Tenting will furnish proof of the superiority of his construction.

THE AUTOMOBILE CLUB OF GREAT BRITAIN.

A MEETING of the Committee of this Club took place on Monday, the 4th inst. The following, amongst others, were elected members of the Club:—The Right Hon. Viscount Templeton (Carlton and Marlborough Clubs), the Right Hon. Sir Richard Paget, Bart. (Carlton Club), H. J. Swindley, Esq., Baron d'Avernas-Salvador (Automobile Club de France), M. Oscar Gregoire (Automobile Club of Belgium), Captain F. E. Dyke-Acland (late R.A., Junior United Service Club), Professor Vivian Lewes (Royal Naval College, Greenwich), Alfred Suart, Esq. (Boodle's Club), M. Marc B. Rey (Automobile Club de France), Pryse Hamilton, Esq. (Royal Yacht Squadron), Percy W. Northey, Esq. (Constitutional Club), William Diggle, Esq. (Royal Yacht Squadron), J. Broughton Dugdale, Esq. (Wroxall Abbey, Warwick), Herr Max Meyer (Automobile Clubs of France and of Belgium), Alleyne Reynolds, Esq. (Sports Club), Arthur E. Greville, Esq. (Northampton County Club), R. E. B. Crompton, Esq. (Garrick Club), Herbert E. Greville, Esq. (Junior Conservative Club), Archibald Weir, Esq., M.A.

The meeting was followed by the monthly house dinner, at which Mr. Roger W. Wallace, Q.C., took the chair. Afterwards a discussion took place on "Motor Touring at Home and Abroad." A paper prepared by Mr. Frederick R. Simms was, in his unavoidable absence, read by Mr. C. Harrington Moore. Mr. Sturmey, Mr. Clarkson, Mr. Estcourt, and others took part in the interesting discussion which followed.

The Easter Tour.

THE Automobile Club of Great Britain is showing vitality and vigour.

The Easter tour on motor-vehicles has proved to be very successful, and all who took part in it are delighted with the result of the experiment. The tour was in no sense a race or competition, but a pleasure journey pure and simple. The company numbered about 30 gentlemen, including Viscount Bangor, Sir Somers Vine, Mr. Linley Sambourne (*Punch*), Mr. Roger Wallace, Q.C., Mr. Holland Tringham (*Illustrated London News*), Prof. Boverton Redwood, Mr. Worby Beaumont, &c., &c. The route, full details of which appeared in the March number of THE AUTOMOTOR, was through Guildford, Winchester, Chichester, Arundel, Littlehampton, Worthing, Brighton, Lewes, Uckfield, Tunbridge Wells, and back to London by Sevenoaks.

The following are a few particulars of the carriages participating in the tour:—

(1) *Mr. Frank Butler's Benz* ($2\frac{9}{10}$ H.P.), a pretty little carriage fitted with a hood, to carry two people, behaved badly at first by stopping in St. James's Street, but overtook the remainder of the carriages at Esher, and, except for a twisted axle owing to tram lines at Southsea, ran well throughout the remainder of the tour.

(2) *Mr. W. M. Hodge's char-à-banc*, which is built by the Motor-Van and Wagon Company, is handsome and comfortable. Bad luck attended this vehicle's engines during the earlier stages of the tour, but not sufficiently to prevent its carrying out each day's programme. It carried six persons throughout the tour.

(3) *Mr. Instone's wagonette* (built by the Daimler Motor Company) also carried a party of six, and showed splendid qualities until the last day, when it was troublesome for awhile, but eventually ran up from Tunbridge Wells to London in fast time.

(4) *Mr. Herbert Capel's Coventry motette* (with Mr. Thomas Clarkson as passenger) showed very good pace throughout the tour.

(5) *Mr. Carter's Bollée voiturette* only joined the tour here and there, as the distances set out in the tour programme were not sufficiently long to satisfy the ambitions of the owner. The voiturette was seen at Winchester on Saturday morning and at Worthing on Sunday night, having in the interval run to Bournemouth and from thence, viâ Southampton, to Worthing.

(6) *Mr. Hewetson's Benz* ran as far as Brighton, where it left the tour route and returned direct for London.

(7) *Mr. Harrington Moore* accompanied the vehicles in his *Hurtu* sociable as far as Esher.

(8) *Mr. Estcourt's Daimler* did not behave well after Worthing, but completed the whole tour.

(9) *Mr. Heyerman's Mors carriage*, with its four cylinders, attained great velocity. This carriage also left the tour route at Brighton and went to London direct

(10) *The wagonette* hired for the Club was a well-known *English Daimler* which has run some 6,000 miles. The carriage ran up from Brighton on the day of the start and throughout the tour behaved admirably until Tunbridge Wells was reached, where a valve required some attention. But as soon as this was put right she ran through to London in capital time.

(11) *Mr. Armstrong's Coventry motette* accompanied the tour only as far as Winchester.

(12) *Mr. Buttemer* only entered his *Benz* for the run from Guildford to Cosham, and the carriage covered this distance excellently.

(13, 14, and 15) *Mr. Edge's Coventry motette* and two *de Dion tricycles* ran from Fareham to Chichester in splendid time.

(16) *Mr. House's steamer* ran up from Southampton on Good Friday, met the tour at Alton, and accompanied it to Worthing, working extremely well.

(17) *Mr. Tinne's Daimler* ran from Brighton to Tunbridge Wells, but was not very lusty.

(18) *Mr. Eyre's* large *Benz*, which ran from Hastings to Crowborough, was not entered for the tour, but joined it for the run from Uckfield to Crowborough.

It will be seen that six carriages completed the whole tour route and that three others left it at Brighton, while in all 18 motor-vehicles took part in it.

The complete journey was about 221 miles. The Club is to be congratulated that this the first organised pleasure tour on motor-vehicles has been carried out without accident and with such eminently satisfactory results.

It is contemplated to organise a further tour in the Eastern Counties at Whitsuntide, and to make arrangements for members who have not motor-vehicles to have seats in carriages to be secured by the Club. It is further intended to have "evening runs" for dinner at various hotels within 15 or 20 miles of London.

Motor-Car Machinery.*

MOTOR-CAR machinery may be taken to cover all the mechanical appliances on a motor-car, and the purpose of this paper is to promote a general discussion upon motor-car machinery; but in the short time available to the opener there will be more than sufficient subject-matter if the paper is confined to the propelling machinery of motor-cars.

It was pointed out at our last meeting that past inventions should not be ignored by the modern motor-car designer. The most successful of past inventions is the horse, and there is, perhaps, a danger of ignoring the peculiar features and excellences of its propelling machinery, which make the horse so difficult a motor to supersede. The horse can, without any change of gear, alter its pulling force to anything from zero up to 700 or 800 lbs.; there is no immediate trouble in getting rid of the products of combustion; all the machinery and bearings are most efficiently encased and protected against dust; and vibration does not cause it to leak at the joints. If, instead of ignoring these good points, the constructor carefully studies them, they may all be realised and embodied in the tireless motors that it is our business and desire to improve.

An engineer starting out to design the propelling machinery of a car has first to select the form of potential energy of propulsion that he can best employ. It may not be necessary to point out that the best form of potential energy for a particular service will depend upon the conditions. For example, if oil is obtainable in a particular district, and electricity is not to be had without putting down special plant for its generation, he would probably decide upon oil if satisfied as to the efficient working of the means available for its utilisation.

The forms of potential energy at present available are practically limited to fuels—solid, liquid, and gaseous—compressed air, and electric storage batteries. A few words on each may not be out of place, and first as to fuels.

The energy that is locked up in fuels is got out and made evident

* Excerpt of paper read on March 21st by Mr. T. CLARKSON, A.M.I.C.E., before the Automobile Club, London.

by burning it, but the burning may be conducted in a variety of ways. Solid fuel may be consumed as on an ordinary grate, or it may be pulverised and then delivered automatically by a mechanical device along with a regulated air-supply, and then burnt in the combustion chamber—or its active chemical parts may be previously converted into a gas before it is burnt. Solid fuel was the source of power in nearly all the "past" inventions, that it may still satisfy some people if they do not mind occasional smoke, sulphurous fumes, clinkers, and more or less irregular firing. The title liquid fuel covers all combustible oils and spirits, but commercial considerations practically limit it to the lighter mineral oils or volatile essences—ordinary lamp oil of domestic use—and the heavy residues from the refinery. These three severally require different treatment for their complete combustion. The heavy residue is the cheapest form, and may do for some of the heavier types of car, but is not likely to come up to the standard of cleanliness and silence in operation that is required in a pleasure car. Therefore, the choice of fuel for lighter traffic practically rests between volatile mineral spirits and ordinary domestic lamp oil. The former burns readily, either inside or outside of an engine, as practically the whole of it is volatilised at a temperature of only 60° F. The ordinary lamp oil is more complex in its combustion; if a little of it is boiled and ignited in a water-jacketed saucepan it would burn for a time and then go out, and, however vigorously the surrounding water may boil, the oil that remains cannot be ignited until it is heated to a much higher temperature, either over an oil bath or directly over a flame. This demonstrates that the oil is not a homogeneous substance, but that it is really a mixture of oils of different degrees of volatility, and this fact, doubtless, accounts for the unsatisfactory results that have sometimes been obtained especially in internal combustion engines. This oil can, however, be consumed completely without smoke, smell, or noise in a suitably-designed burner, and giving either a luminous or a bluish flame, the heat being utilised either to generate steam or, when the appliances are improved, for the direct generation of electricity.

Lamp oil is much safer than the more volatile oils now commonly used; it is about half the price and can be obtained anywhere. Very much could be written on this burner question, but as it is only one detail I am obliged to pass on to the others.

Gaseous fuel is clean, but does not give the potential energy in a very concentrated form, and supplies of compressed gas are not generally obtainable. The same remarks apply to compressed air.

Electric energy is very desirable in many ways, but it will not be suitable for general purposes until charging stations are abundant all over the country, even when the accumulator leaves nothing more to be desired.

It must not be forgotten that there is a reciprocal influence between the design of car and type of machinery best suited for it. In some cases, as in a van, it is easy to remove the products at the top, but for a pleasure carriage I have doubts whether anything in the nature of an uptake, even when disguised by a hood or canopy, would be taken kindly to by the public. It is obviously the most natural way to remove heated air at the top as it always tend to rise. If an uptake is considered to be an eyesore the products can be removed downwards, but at the expense of a superior impelling force which may sometimes fail and cause trouble. It is useful to remember the old saying that "Nature is only conquered by obedience," and the tastes of both designers and users of cars need to be developed in the light of this truth.

A word on the internal combustion engine. It is simple, there is no boiler or stoking, and this has appeared to many to supply the shortest cut to the building of a motor car. Further consideration of the power conditions on a motor-car reveals that the principle of intermittent impulses is about as unsuitable as anything can be, and the unsuitability is not diminished by the fact that the engine must be kept running at nearly full speed all the time, and cannot be started from the seat. It is easy to point out what has been done by this type of motor notwithstanding these unsuitable conditions, and this I fully appreciate, but all the same I do not regard this as the ideal type or as representing finality of design.

Furious Motor Cycling.—John Wilson Taylor, of Weybridge, was fined £5 at Chertsey Petty Sessions, on the 13th inst., for furiously driving a motor-cycle on the highway. A police inspector said that the motor was being driven at a rate of 18 miles an hour. When asked how he arrived at the speed, the inspector said he was riding a high-geared cycle, weighing only 25 lbs., and could not catch the motor.

REVIEWS OF BOOKS.

"The Contour Road Book of England." By HARRY R. G. INGLIS. (London: Gall and Inglis, Paternoster Square, 1897.) Price 2s.

WITH the extension of cycling and locomotion by motor-vehicles, there has arisen a desire to know something of the nature of the roads and districts traversed. It is a striking instance of the degrading influence of animal traction and the cultivating and refining influence of mechanical traction upon mankind, that whereas our forefathers, who travelled by mail coach, knew little and cared less about local geography, those who employ cycles and motor-vehicles exhibit a keen and intelligent interest in not alone the roads but in the surrounding country. Formerly travellers were content to know that the next stage was so many miles off, and that the road was good and the hotel accommodation likewise. Nowadays we require to know distances and gradients of roads, climate, scenery, and industrial capabilities of districts. With this knowledge we convert what would otherwise be an uninteresting peregrination into an educational influence of great value. Road books and maps have now reached a point of considerable excellence, but hitherto little has been done in contour mapping, information of a reliable nature about gradients being difficult to obtain. Local surveyors in many cases regard such information in the light of a State secret. Thus we ourselves recently had occasion to learn something of the gradients in and around Liverpool, but on application, the local or municipal surveyor actually could not supply it unless be was directly instructed to do so by the Liverpool Town Council! Needless to say we did not trouble that august body, but got the data from another source. In a really civilised town the geography of each street would be verbally and graphically exhibited at each street corner. Thus a traveller would see at a glance the direction, length, breadth, grade, paving, and general topography of a street and district. Although this municipal improvement is not yet likely to be realised, not even by such an advanced body as the London County Council, private enterprise is helping to disseminate such useful information. Thus in France the Automobile Club exhibits such notices on boards; the Cyclists' Club and the British Automobile Club are also working in the same direction, and now Mr. Inglis has compiled, evidently at great pains, a series of small handbooks, which enable the intending visitor to obtain all the necessary local geographical information and arrange accordingly. Thus for each town a short description is given of the roads and their gradients; then follows a table with distances from surrounding towns. The principal objects of interest and the very important information relating to hotels are also stated. Each route is graphically illustrated by contour sections. This is a very decided and welcome addition, and greatly enhances the value of the book. Unfortunately, the scale adopted is too small: thus the abscissæ are spaced ¼-inch to the mile, and the ordinates are ⅛-inch to 1,000 feet. Such scales are much too small for scientific automobilism, but no doubt useful enough to cyclists. The great merit of these charts is that they convey by a glance the nature of the route, and that without any study or special knowledge. Altogether, the work is one of distinct value, and we can cordially recommend it.

Transactions of the American Institute of Electrical Engineers.—The issue for January contains some valuable papers, the principal being one by Mr. Richard Lamb on "The Development of Electric Cableways." This is a form of automobilism little known in this country, and only of recent growth in the States. As a means of effecting cheap transport in new countries this system has much in its favour. It differs from ordinary telo-dynamic transmission in that each trolley or carriage carries its own electric motor. According to the paper this system consists of a carriage with grooved wheels in tandem that move upon a cable or suspended trackway. From this carriage is hung a frame pivoted to the carriage so that it can maintain a vertical position regardless of the grade of the track. This frame holds an electric motor, preferably of an iron-clad cylindrical type. The motor is geared to an elliptically grooved sheave. A steel cable is wrapped around this sheave two or more times, and is anchored at both ends. For the sake of economy in conductors the upper or bearing cable is insulated from the lower or traction cable, and is used to carry the electric current. The carriage is insulated from the suspended frame and motor. An insulated wire is attached to the carriage and conveys the current to the rheostat. The other pole of the rheostat is connected with a convenient part of the suspended frame. The rheostat is designed to control the speed and reverse the current. A circuit-breaker is put in circuit. The current from the generator passes along the bearing cable to the carriage, thence through the insulated wire, through the rheostat, through the motor, to the frame of the motor, thence through the traction cable back to the generator. The paper is very full of detailsland is worth study. "Sparking, its Cause and Effects," will appeal to those in charge of dynamos and motors, and also to those engaged in running electric motor-vehicles. But should a properly designed dynamo spark at all? There is also an interesting but not very instructive paper on "Wireless Telegraphy," in which the Marconi, or, as we prefer to term them, the Hertzian, experiments of electric pulsations are described.

Der Motorwagen Zeitschrift des Mitteleuropäischen Motorwagen-Vereins.—Automobilism in Germany has progressed sufficiently to warrant the issue of a journal devoted to its interests, and we cordially welcome this latest addition to our library on the subject. The first number contains illustrations and descriptive matter of various Benz vehicles, electric cabs, electric railway carriages, &c., and is well printed on excellent paper. It is published monthly in Berlin, by Druck von Pass and Garleb, and its price is 1·50 marks.

Revue de Méchanique.—This high-class publication is as usual replete with good matter. The January number contains an excellent essay upon turbines by M. Flamant, the theoretical analysis being very complete. The practice in the design and cutting of teeth, as prevailing in England and the United States, is described by M. Lecornu, who points out that the American methods are in many respects better than those prevailing on this side. Just now the question of superheating is attracting the attention of engineers, and M. Sinigaglia contributes an article on the subject. This is followed by an excellently illustrated article by M. Camille Roche, describing the machinery of the French battleship "Brennus." M. G. Richard discusses the various applications of gas and oil motors. For pumping and irrigation work these are largely superseding steam-engines. Light oil-motors are most successfully applied to fire-engines, but, needless to say, our London County Council Fire Brigade is not alive to the advantages of this new method of obtaining increased efficiency. Petroleum (heavy oil) motors are also used in operating mechanical ploughs. The motor is of 12 H.P., and runs at 420 revs. per minute. The Howard and Bousfield portable motor is also described. We learn, too, that oil-motors are most successfully employed on board lightships for compressing air for the fog-horns or sirens, while in small craft it is much used, as is well known, in propulsion. The article is well worth perusal by automobilists. There is a good description of a duplex petrol-motor for vehicles. This we shall reproduce in our next issue.

In the February number the principal articles of interest to our readers are one on "Turbo Machines," by M. Rateau, and one on "Mechanical Traction," by M. Barbet; in the latter the various systems of compressed air for tramways are described and discussed.

The Engineering Magazine.—The number for March contains, among other matter, a useful article on "The Economical Utilisation of Exhaust Steam" in which the merits of condensers are examined. This article being by Mr. Bryan Donkin, it is needless to say that the subject is most scientifically examined, but while the learned author describes jet, surface, and air and water surface condensers, and discusses their respective merits, he does not tell us how to solve a problem that is now occupying very largely the attention of many readers of THE AUTOMOTOR, viz., How to condense the steam from the exhaust of steam motor-vehicles. We would suggest to our contemporary that an article from Mr. Bryan Donkin on this subject would be extremely welcome.

Nautical automobilism is treated by Mr. Jas. McKechnie, the engineer-in-chief of the naval shipbuilding firm at Barrow, in the shape of an article entitled "Shipbuilding as a Productive Industry." This is copiously illustrated. The author takes a rather pessimistic but, we think, justifiable view of the industry in this country. Say what we may about the evil results of strikes, it is out of the question to expect working men to cease to agitate for higher pay and shorter hours. We all strive for this. Mr. McKechnie speaks of British mechanics being driven to foreign employment through the "unscrupulous exactions of trade unionism." There is no doubt a great deal of tyranny exercised by these bodies towards members of their own class, but it is not likely that a trades union will ever exercise a preponderating influence on all industry to the extent of making all the workers join it and obey its behests. It is now recognised by leading economists that the influence of a trades union is strictly limited, and as education becomes more disseminated among working men the limitations of trade unions will be more apparent.

"The Construction of Slow-Burning Buildings" is rather *apropos* in the light of the recent City fire. "British Railway Fares" is an exhaustively discussed subject by Mr. W. J. Stevens, and may be read with advantage by travellers and shareholders. "The Development of Metal Stamping" is a most useful article and one which appeals to automobilists who are particularly interested in associating lightness and strength. Needless to say, metal stamping has been brought to its present state of perfection mainly by the efforts of American engineers. We have, however, led the way in the production of heavier stampings. Thus the Leeds Forge Company press or stamp out all the framing of railway wagons and carriages, and no doubt this enterprising firm will devote its attention to the stamping of frames for motor-vehicles when these latter shall have become "selected" into distinct types.

CATALOGUES.

WE have received from MM. Th. Cambier et Cie., of Lille, a neatly got-up catalogue and price list of their motor-vehicles. This firm manufactures 10 distinct types of vehic'e, and the motor is either a one, two, three, or four-cylinder one, according to the power required. Light petroleum (petrol) is used as the source of energy. According to the illustrations which are given, the light vehicles seem to be rather elegant, but the heavy ones do not err in this direction.

THE FLYING CHARIOT.—Under this somewhat ambitious title Messrs. W. H. Dunkley, of Birmingham, who manufacture nearly everything connected with automobilism, have issued a catalogue descriptive of their perambulators and bassinettes (which can hardly be designated as flying chariots) and cycles. Not being in the position to utilise the domestic "pram" we can only judge of Messrs. Dunkley's specialities in this direction by taking feminine opinion. Having conscientiously done so we are pleased to say that they are all that the fondest mamma and the most captious nursemaid could desire. As regards the cycles we are on firmer ground. The designs seem to be very good, especially those of the delivery cycles, which are now becoming so much used by shopkeepers and others.

IVEL CYCLES.—Mr. Dan Albone, of Biggleswade, Beds, is a well-known cycle manufacturer who more than holds his own, in spite of the fierce competition that prevails. His models are characterised by lightness, elegance, and strength. His catalogue is well illustrated and his prices remarkably low.

WE have so fully described the advantages of roller bearings in our pages, particularly the system as fitted by the Roller Bearings Company, that we need say little more than that this Company has lately issued a well-got-up catalogue illustrating the various uses to which roller bearings are applied. These include vehicles of all descriptions, and generally all kinds of shafting. Railway companies, generally the most conservative of institutions, are slowly adopting roller bearings, while the Liverpool Overhead Railway is fully equipped with them. The address of the Roller Bearing Company is 1, Delahay Street, Westminster, S.W.

WE have also received:—*The Journal of the Society of Arts, The Indian Engineer, Industries and Iron, The Practical Engineer, Coach-Builders' and Wheelwrights' Art Journal, The Journal of Acetylene Gas Lighting, Knowledge, Machinery Market Review, The London Chamber of Commerce Journal, Indiarubber World, Cyclist, Scottish Wheel, Irish Field, The Yachting World, The Engineering Magazine, La Revue de Méchanique, La Locomotion Automobile, La France Automobile, L'Industrie Vélocipédique et Automobile, L'Automobile Illustré, Les Sports, L'Energie Électrique, Der Motorwagen, Samokat, Horseless Age, American Wheelman, The Motocycle, Australasian Coach-Builder and Saddler,* &c., &c.

CORRESPONDENCE.

*** *We do not hold ourselves responsible for opinions expressed by our Correspondents.*

*** *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion or containing queries.*

*** *Correspondents are particularly requested to write on one side of the paper* ONLY, *to place the subject of their letters as a headline at the top of the sheet, and their names and addresses at the foot. Attention to these matters saves much time and ensures the insertion of the letter.*

THE PRICE OF PETROLEUM.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—In your AUTOMOTOR POCKET-BOOK, p. 105, you give prices of oils. We should be glad if you can give us names of firms who can supply us with Royal Daylight or American Ordinary at the prices named. We cannot buy as low at present in this neighbourhood.—We are, yours faithfully,

THE LANCASHIRE STEAM MOTOR COMPANY,
Leyland. F. J. P., Secretary.

[The prices quoted by us are fair average values. We have ourselves purchased in Liverpool petroleum by the barrel at something like 3½*d.* per gallon. We would recommend you to apply to the Anglo-American Oil Company in Liverpool. This Company quotes us as follows:—Tea rose, ex-wharf, in own tanks, 4*d.*; in barrels, 4¾*d.*; allowance for empties, 4*s.* 4*d.*; which makes the price 3½*d.* per gallon.—ED.]

THE DAIMLER MOTOR AND WHO SUPPLY IT.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—I shall be glad if you will kindly insert the annexed correspondence under the above heading in the next issue of your JOURNAL. In making this request I take the opportunity of stating that not only is my Company able to supply Daimler motors ranging in size from 2 to 10 H.P., but it is *the only Company manufacturing Daimler engines in this country*, other suppliers either procuring from us or importing under certain conditions from the Continent. The motors manufactured at my Company's well-known Coventry works are of British workmanship and materials throughout, and embody all the most recent improvements, except such as have not yet passed the experimental stage.—I am, yours faithfully,

ERNEST M. C. INSTONE, Secretary.

Daimler Motor Co. (Ltd.),
219 to 229, Shaftesbury Avenue, W.C.,
April 2nd, 1898.

[Correspondence enclosed.]

The Secretary,
The Motor Carriage Supply Co. (Ltd.),
Donington House, Norfolk Street, W.C.

Dear Sir,—The attention of my Board has been called to your letter of the 23rd ult. to the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL, which, together with copy of its enclosure, appears in the current number of that paper.

I am instructed by my Board to point out to you the inaccuracy of the statement in your letter to Mr. Wrightson, which is to the effect that he will find there is no firm besides yourselves able to supply Daimler motors of 4, 6, 8, and 10 H.P. As my Company is in a position to do this, I am directed to request you to withdraw the statement referred to as publicly as it has been made.—Yours faithfully, (Signed) E. M. C. INSTONE, Secretary.

March 22nd, 1898.

E. M. C. Instone, Esq.

Dear Sir,—We are in receipt of your letter of the 22nd inst., pointing out that a statement made by us in a letter to Mr. Wrightson that we were the only firm in this country who can supply Daimler motors of 4, 6, 8, and 10 H.P. is inaccurate.

If your Company are manufacturing motors of more than 4 or 6 H.P., we need not say that we regret if we have been misled into making a statement which is inaccurate so far as your Company is concerned. We shall take the earliest opportunity of rectifying the error, and shall have no objection to your giving what publicity you wish to this letter.

We may be excused if we have fallen into an error, inasmuch as we do not remember having seen any price list or circular of your firm referring to any motor-vehicle of more than 4 H.P. ready for delivery.

We are interested to hear from you that you are prepared to supply 10 H.P. vehicles, and would like to know within what period you could deliver, as we have ourselves numerous enquiries for vehicles of this capacity for immediate delivery.—We are, yours obediently, (Signed) E. E. LEFEBURE, Secretary.
For the Motor Carriage Supply Co. (Ltd.).

March 23rd, 1898.

E. E. Lefebure, Esq.

Dear Sir,—I placed your favour of the 23rd inst. before my Board, at a meeting held on Thursday last, and am instructed to inform you that my directors accept with pleasure your expression of regret, and appreciate your kind promise to take the earliest opportunity of rectifying the statement complained of.—I am, yours obediently, (Signed) E. M. C. INSTONE, Secretary.

March 26th, 1898.

AUTOMOBILE CLUB DE BELGIQUE.

À Monsieur le Rédacteur AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

MONSIEUR,—Nous vous serions obligés de bien vouloir insérer dans votre estimable journal l'information suivante :—

La course Bruxelles-Spa, qu'organise l'Automobile Club de Belgique pour les 25 et 26 juin produit à l'étranger un vif mouvement de curiosité. Sir David Salomons, le promoteur du mouvement automobile en Angleterre, a offert à l'Automobile-Club un prix de 500 francs destiné aux concours qui suivront la course à Spa. Ceprix sera décerné à la voiture la plus élégante et laplus comfortable parmi celles qui auront été inscrites. C'est la une heureuse idée, car l'on a souvent reprobé aux voitures automobiles leur aspect disgracieux, et il est bon d'encourager également les efforts des constructeurs danz cette voie.

Veuillez agreer, Monsieur le Rédacteur, avec nos remerciements, l'expression de nos sentiments distingués.—Pour le Comité Directeur,

Le Secrétaire Général,
COMTE F. DE VILLEGAS DE ST. PIERRE.

14, Place Royal, Bruxelles.

THE "DAILY NEWS" AND THE TRANSMUTATION OF METALS.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—On p. 141 of your January number you very rightly condemn the opinions of the daily Press on scientific matters as usually erroneous and misleading. But in the course of your remarks reference is made to some statements in the *Daily News* under the heading of "Transmutation of Metals," and you state that this paper has been "had." If, however, you refer to Professor J. J. Thomson's paper on the Cathode rays in the *Philosophical Magazine* for October, 1897, you will see that he considers that *all* matter is broken up into particles of the *same* substance by these rays, which particles may recombine to form *any* other substance.

We have, then, the possibility of not only converting silver into gold, but anything else into gold, under suitable conditions. To prevent any of your readers from investing in a plant and setting up a gold factory, it will be well to mention that Professor Thomson also says that the coil he used, "if kept working continuously for a year, would only produce about one three-millionth part of a grain of altered substance," which, of course, might not even be gold.

It is probable that his remarks have been well magnified by a double passage across the Atlantic, hence the article in the *Daily News*.—I am, &c., H. H. FRANCIS HYNDMAN.

Trinity College, Cambridge,
February 26th, 1898.

THE BICKFORD PETROLEUM BURNER.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Having been from the first number a constant reader of your most valuable paper, and seeing how vital the question of what means shall be adopted to raise steam so as to give the best result, I feel anxious to add my little word, so as to help some who are undecided what means to adopt. We have a boiler at work: the dimensions are these:—Vertical, no tubes, holds 40 gallons of water. Now, in the usual way we use coal; it took us 45 minutes to raise 40 lbs. steam from cold. Now, having a desire to use petroleum to get up steam, we applied to the firm of Bickford and Co., Camborne, Cornwall, for one of their burners, which they sent on approval. We have given this burner six weeks' severe testing, and we have found it to work without trouble. My son, 13 years of age, has on several occasions entirely started this burner and raised 40 lbs. of steam in the above boiler in 25 minutes. Now, I affirm that this proves that petroleum, if properly applied, gives off a very great deal more heat than fire from coke or coal in the same class of boiler.

Trusting these few remarks *re* oil fuel may be of some service to your many readers in directing them to a firm who can supply them with an oil apparatus capable of doing the work they require.—I remain, yours very truly, H. Evans.

Worcester, *March 17th*, 1898.

[The experience of our correspondent is useful as confirming the well-known superiority of petroleum as a fuel when properly burnt. On p. 104 *et seq.* of The Automotor Pocket-Book will be found a very full account of the heating values of various fuels and descriptions of petroleum burners.—Ed.]

CYCLE GEARING.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—What is meant by a cycle being "geared to 60," and how can I find out how far my machine will go in one revolution of the crank? I never see practical rules given in the cycling papers which contain mostly gossip and "records." I have also looked up "Modern Cycles," by Wallis Tayler, but do not find the information. I have tried a cyclometer but find it unreliable. A reply in your next issue will oblige your subscriber, A. Jones.

Stratford, E., *March 31st*.

[The figure denoting the gearing gives the diameter of a wheel which bears the same ratio to the driving wheel as the crank wheel does to the hub wheel. Thus, suppose a hub wheel has 10 teeth and the crank wheel 25, and that the diameter of the driving wheel is 28 inches, then this relation obtains—$\frac{10}{25} = \frac{70}{x}$, whence $x = 70$, and such a machine is said to be "geared to 70," the 70 being the diameter of a wheel which has the same ratio to the driving wheel as the crank wheel bears to the hub wheel. In order to find out how far the machine will go during one revolution of the crank multiply the number it is geared to by π (3·14), thus $70\,\pi = 219{\cdot}8''$ = 18·3′. Another rendering of this rule is—multiply the number of teeth on crank wheel by circumference of driving wheel and divide by teeth on hub wheel. Cyclometers as at present made are of little practical value; they are mere toys, and useless for accurate work.—Ed.]

FLY-WHEELS FOR MOTORS.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—I note your reply to my letter in this month's Automotor, *re* the weight of oil-motor fly-wheel. I do not see why, if the French find a lighter fly-wheel answer, one should use a wheel as heavy as a French motor and fly-wheel together, especially considering the fact that it does not matter how irregularly the motor runs (as long as there is no fear of it stopping) when *out* of gear, and when *in* gear the momentum of the car would carry the engine over compression stroke without a fly-wheel at all. What would be the largest ratio of maximum to minimum speed per cent. allowable? I understand that the Daimler motor has an open water-jacket. This system has many advantages, but what are its disadvantages? The temperature could not rise above 212° F., but could the piston be kept properly lubricated at this temperature?

I cannot find any reference to an air-condenser in the March issue. Was it omitted? Thanking you for your previous answers.—Yours, &c., B. A. Payne.

Netley, Old Christchurch Road, Bournemouth,
March 28th, 1898.

[We are always pleased to answer questions on technical matters, but we cannot be expected to act as a consulting engineer in regard to machinery we have never seen and whose features of design we are unacquainted with. We also do not see why, if the French find a lighter fly-wheel answer, one should use a wheel as heavy as a French motor and fly-wheel together. It depends entirely upon what one requires. If you want uniform power, then a heavy fly-wheel such as we mentioned is necessary; if large fluctuations in power and speed are not undesirable then French practice is permissible. Our correspondent must bear in mind that in the very light French motors to which he refers the vehicle is relied upon to act as the fly-wheel. The momentum of the car does *not* carry the engine over the compression stroke, but the kinetic energy stored in the car *does*—a dynamical error very often made. It is quite out of the question for us to say what would be a permissible variation of speed. You had better consult a good engineer. There are no disadvantages in an open water-jacket; on the contrary, the Daimler system is good, and their water-jacket constitutes an excellent feature. The piston can be well lubricated at far higher temperature providing a good mineral oil of high flash-point is used. Owing to pressure of space the article on air condensers was crowded out in our last issue. It, however, appears in this. Our correspondent will find much valuable information in Grover's "Modern Gas and Oil Engines."—Ed.]

THE STEERING OF MOTOR-VEHICLES.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—In one of your recent issues you stated that the pivoted wheels carried in forks on the front of most motor-cars should always be normal to their respective radii of the curve in which the vehicle is turning. Can you tell me what kind of gear permits this to be done. Do you recommend forked wheels?—Yours truly,

Glasgow, *March 19th*, 1898. A. Adamson.

[Ackermann's and Bollée's steering gear fulfil this condition better than any we know of, but we do not think they comply with it for all curves. Forked wheels are undoubtedly the proper things to use, as they do not diminish the stability when turning. They require, however, to be strongly fixed, as in turning they are liable to be severely stressed.—Ed.]

CROWDUS STORAGE BATTERY.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—In reply to your remarks in your last issue (p. 236), I beg to inform you that I hold the British and foreign patents of this invention, and enclose data for your perusal. I last week received some cells from Chicago, which have been charged by, and are now with, Messrs. Cathcart and Co., Dorset Buildings, Salisbury Square, and they have my instructions to allow you or your engineer to test them whenever you wish to do so. After practical tests you may have a good opinion of this invention.—Yours truly,

John T. Bowden.

City Carlton Club, St. Swithin's Lane, E.C.,
March 23rd, 1898.

P.S.—If you refer to the *Electrician* of last week (p. 682), you will find a description of this battery.

[From the reports, &c., accompanying the above letter, we gather that a Crowdus cell, weighing but 8 lbs. complete, has a capacity of 75 ampère hours at a 10 per cent. rate of discharge—*i.e.*, for 10 hours it will give practically a constant current of 7·5 ampères at, we presume, a constant E.M.F. of 2 volts. One of the best-made British cells we know of, weight 8 lbs. complete, has a capacity of 30 ampère hours—*i.e.*, it will give, at a 10 per cent. rate of discharge, 3 ampères for 10 hours. In other words, the Crowdus cell is, other things being equal, two and a half times better than the

British cell. Again, according to the report of Mr. Jas. K. Pumpelly, "the 100 ampère-hour battery (we presume cell is meant) weighs but 14 lbs., and will give an output of 20 ampères for 4 hours, or 15 ampères for 6 hours"—that is, this 14-lb. cell has a capacity of 90 ampère hours, or 180 watt hours. A very well known British cell, much used in traction work, with a capacity of 100 ampère hours, weighs 35 lbs. Hence the Crowdus cell is again practically more than two and a half times better than one of the best British cells; or, if not two and a half times better, it is, at any rate, but two-fifths the weight of one of the best British cells. We are then told: "These batteries have been at work for months in propelling delivery wagons in Chicago six days a week, in all kinds of weather, and over the worst streets in the world, while under the control of drivers whose main desire was to finish the trip in the most rapid time possible; and, in fact, two delivery wagons of the Chicago Silk Store have been running daily since June last over these rough streets, and making runs of 30 to 42 miles daily, with stoppages averaging three to a mile; besides which, light carriages have been going constantly daily for the past six months. The wagons have 44 13-lb. cells, and the carriages 28 13-lb. cells." Taking the case of the wagons, and assuming the same rate of discharge as before—viz., 15 ampères for 6 hours—the H.P. given to the motor is 1·77, assuming no losses through extra resistance due to bad joints, &c. Now, a loaded "wagon" simply cannot be propelled through Chicago streets (some of the worst streets in the world, as is truly remarked in the foregoing excerpt, are to be found in that Western Babylon) at a reasonable speed with this power, and traversing the distance stated, viz., 30 to 42 miles. A London electrical cab (*vide* The Automotor, Vol. I, p. 485) has a battery of 40 cells, each with a capacity of 170 ampère hours when discharging at 30 ampères—that is, it delivers to the motor about 3·2 H.P., or this cab takes about twice as much H.P. as the wagon. Evidently there is some mistake, because a battery of 44 100-ampère-hour cells could only furnish 3 H.P. for 1·7 hours. Leaving this, however, merits are claimed for the Crowdus cell which have so far not been obtained in any cell yet made in this country. We have no wish to depreciate such claims, because we know as well as anyone the tremendous and unlimited scope there is for a cell as light and as efficient as the Crowdus cell is said to be. No useful purpose would be served by us accepting Mr. Bowden's invitation to test the battery, as, unless the claims made for it are substantiated by unquestioned scientific opinion, nothing less said in its favour would be believed. We would suggest to Mr. Bowden that he send a battery of his cells to the Electric Testing Department of the Board of Trade, or subject it to independent tests at the hands of some of those members of the electrical engineering profession whose names it would be invidious to mention, but whose report would be accepted by possible users.—Ed.]

THE MOTOR-CAR ATTACHMENT COMPANY.

To the Editor of the Automotor and Horseless Vehicle Journal.

Sir,—One of your inquirers in the current issue asks information *re* the Motor-Car Attachment Company. The Company is working under Carmont's Patent, and had works in 1897 in Kingston, and offices in Basing House, E.C. They claim patent for putting motor as a tractor—not for any specified mechanism, electric, gas, or oil, but merely motor in front.—Yours truly,

Jas. Melling.

Metalling for Roads.—According to some tests made recently by Messrs. Kirkaldy a stone known as "Rowley Rag" is superior in hardness to others. As is usual in testing stone, three cubes were submitted to the test with the following results:—No. 1 crushed at the enormous stress of 33,333 lbs. to the square inch; No. 2 crushed at 32,243 lbs.; and No. 3 at 25,052 lbs. This gives a mean stress upon the three cubes of 30,543 lbs. to the square inch, or a resisting strain of over 3,000 lbs. higher than that of any other class of stone selected from 16 of the principal quarries in the kingdom.

PROCEEDINGS OF TECHNICAL SOCIETIES.

Automobilism on Roads.*

(*Concluded.*)

Now, I believe improvement of our common roads to suit the possibilities of mechanically-propelled vehicles, and the design of the vehicles to suit the possibilities of high roads, will in the future make a change almost as vast as that which has been wrought by the mechanical horse on iron roads. We have our roads leading from everywhere we want to go or send goods to our houses and factories. We want to take advantage of the powers which the steam-engine will place in our hands, if we will but give a fraction of the ingenuity to the construction of roads which we have given to the construction of this world-changing motor.

There are at work at the present time no less than 100,000 horses in London alone. These horses are not only destroying our streets and roads at double the rate at which even the iron-shod wheels would do it, but they are themselves the origin of an enormous quantity of street haulage. Nearly all the food and fodder has to be hauled over some parts of the roads and streets. Food and fodder alone represent 20,000 tons per week; the street refuse, which employs an army of scavenging boys, and then scavenging carts and more horses, to carry away from the street boxes that which is not blown into the air we breathe or washed into the sewers, will represent another enormous quantity of street carting necessary to enable these horses to exist in London alone. All this will be avoided by the use of motor-vehicles that are possible even to-day.

This is not a statement of what is desirable; it is a statement bearing on changes which are becoming inevitable. If anyone is inclined to doubt it, let him go to any of the meeting places of our great lines of traffic, and see how nearly impossible has the movement of any vehicle become already. Oxford Street, Fleet Street, Cannon Street, Cheapside, Mansion House Place, Post Office, and many others, are hopeless blocks for several minutes at a time, which total up to many hours per week—hours that represent an enormous loss. At least one-third of the space now occupied by the horses of the vehicles, from great railway vans to hansom cabs, can be saved by the employment of motor-vehicles. This is shown by the electric cabs and the steam and spirit motor-vehicles now growing common. This saving of space is alone enough to increase the accommodation room of the main arteries sufficiently to prevent most of the loss of time.

Nearly half the street repairs and consequent stoppages would be avoided if horses' hammer hoofs were absent, and moderate loads allowed as a maximum per axle.

I said in the commencement of this address that many millions sterling—I might say between one and two hundred millions—might be expended with great profit on the construction of new roads, and the improvement and proper maintenance of our high roads. It is necessary to substantiate this by reference to fundamental facts. It is an indisputable fact that the number of horses required, or the distance which horses can haul a load, is inversely proportional to the road resistance, and it is equally well known that speed and load taken together decrease more rapidly than the increase of tractive resistance when that is excessive.

On the best surfaces the draught will vary from 25 lbs. to 30 lbs. per ton on the level. On good well-made macadam roads it may be from 38 lbs. to 60 lbs. per ton on the level. On broken stone road it rises to 90 lbs. to 100 lbs.; and on gravel road to 140 lbs. per ton on the level. On tram rails it varies from 15 lbs. to 40 lbs. per ton of load; and on railways from 6 lbs. to 12 lbs. per ton.

Thus the resistance on good ordinary roads, which might be in use everywhere, is less than one-third that which is met with on common roads everywhere; or, again, it is from three to six times that it need be for the heavier vehicles, if wheel-ways were laid and properly maintained. Hence horses can haul on an asphalte road double the load they can on macadam, or they can continue at work much longer; or 10 horses will do instead of from 15 to 20. Even on a grooved tramway, with its high resistance compared with a flat rail, two horses will haul from 60 to 100 per cent. more load than the same horses can with equal fatigue haul an omnibus on an average macadam road.

* Excerpt from the Inaugural address delivered by Mr. Worby Beaumont, M.I.C.E., M.I.M.E., &c., before the Society of Engineers, London, on February 7th.

This sort of difference obtains with reference to every kind of haulage done on common roads, and I want to point out that it is not the omnibus or other ordinary vehicle owners who suffer this loss, it is the public, and the removal of all this would be to the public advantage in lesser fares, lower freights, greater distance carried for same fares, and great saving of time.

An equally or more important question is that of traction resistance on gradients. This is even more important, in view of the coming of the mechanically-propelled vehicle, than it is with reference to horses, if we leave all humane considerations out of account, and also leave out the much greater rapidity of wear of roads on stiff gradients.

The increase in the power required to haul a load up a hill is directly proportional to the angle of inclination from the horizontal, and hence on a hill of 1 in 20, a very common gradient, the hauling power jumps from the average, on a good macadam road, of, say, 45 lbs. per ton to 45 + 125 lbs., or a total of 157 lbs. instead of 45 lbs. Bad as this is, it is insignificant as compared with the pull required on a gradient of 1 in 10 to 1 in 8, not at all infrequently met with. On 1 in 10 the hauling power required becomes 269 lbs., instead of 45 lbs., or no less than six times the power employed on the average nearly level road. It is to meet this heavy demand for power that two or three horses have often to be sent with a load which, but for the one or two short lengths of steep hill, could be taken by one horse, and it makes it necessary to put on a motor-vehicle, boiler and engine power of from 12 to 16 H.P., where from 3 to 4 H.P. ought to be sufficient.

Now see what all this means in respect of annual loss to the people of this country; or, on the other hand, the gain that would result from that application of capital which would prevent or reduce this loss. There are, it is estimated, in this country over 1,000,000 horses. There were about this number 60 years ago, but as no returns exist showing, even approximately now, the number of draught horses in use, I am taking the nearest approximation I can make and assume that about 1,200,000 draught horses are employed at the present time. In order, however, to under-estimate rather than over-estimate the advantages to be derived from the recognition of road improvement as a source of national income, I will assume that only 500,000 draught horses are at work.

There were at the end of 1896 in London alone 15,204 hackney and stage carriages under licence. Of these 7,585 were two-wheeled carriages, chiefly hansoms; 6,450 omnibuses of various kinds; and 1,169 tramcars. To work these not less than 58,000 horses are employed, and the horses employed in the thousands of trade carts and vans and wagons and the private carriages will be more than this quantity, so that in the London area alone there are probably 120,000 horses. Each omnibus has on an average ten horses to work it, and each hansom and cab two. For these, however, I allow in my estimate only thee horses to two hansoms or cabs to allow for some small proprietors whose cabs are only worked part of a day.

In the United Kingdom there are of licensed vehicles the following in round numbers:—

Hackney carriages	116,000
Other than hackney, with four or more wheels for mechanical or horse haulage	48,000
With four wheels for one horse only.. ..	77,000
With less than four wheels	305,000
Or a total of vehicles requiring licence of	546,000

These represent at least 1,200,000 horses.

I have no means of telling what the total number would be if all the agricultural horses and vehicles which do not need a licence were added. It would probably bring this to over 1,500,000.

Each of these horses will cost for food alone and stabling about £30 per year, and I think I am entitled to assume, from what I have already pointed out, that at least one-third this number of horses could be dispensed with, or that the existing number of horses might be enabled to effect at least 33 per cent. more transport than they do at the present time. Ignoring for the minute the increase in road traffic in the future, which must be provided for, this proves that about 170,000 horses less than the number now employed would need to be kept and fed. If we take only the cost of keep of these horses, and for the present say nothing of the reduced destruction of roads which would result from the removal of these horses, a saving of £30 per year per horse, or a total of £5,100,000, would be effected.

Now, this sum, capitalised at 3 per cent., is £170,000,000 sterling, and enormous as this sum appears, there is no doubt that such a sum might profitably be invested in the roads of Great Britain if we consider the advantages to be derived from mechanical traction. It may, however, be reasonably assumed that the road traffic will grow, so that even a larger sum than this may represent the possible saving.

It is, in fact, the great advantages to be derived from mechanical road transport which will make road improvement desirable, and it is useless to expect either the proper development of mechanical traction, or the possible improvement in the many kinds of ordinary road vehicles, without a corresponding improvement in the roads upon which they are to run.

The better the roads, the less destructive will be the vehicles and their tyres; for exactly the same reason as that which explains the wearing of thin light boots on the clean dry pavements of a well kept city, or perhaps in a drawing-room, by the man who finds it necessary to wear hob-nail boots on the rough roads of the country.

For another estimate of the saving which will result from the proposed improvement in roads we may proceed on the basis of the greater quantity of work every horse now in use could perform, the smaller number of relief horses necessary, and the smaller destruction of roads, horses, and vehicles on the heavy grades now common.

From a careful consideration of these points I am satisfied that at least one horse in every nine or ten could be saved, and that every draught horse in use could earn from £5 to £10 per year more.

If, then, the saving of a horse only represents the cost of its keep, or, say, £30 per year, and if only 2s. per week or £5 per year be taken as the greater average earning capacity of each horse, we have a saving per year on 500,000 horses, of 50,000 horse-keep at £30 = £1,500,000, and of £5 on the 450,000 horses, of £2,250,000, or a total saving of £3,750,000 per year. This sum capitalised at 3 per cent., the rate at which the Government or the country authorities could borrow money, is no less than £125,000,000.

Thus, after basing every gain on the lowest estimate, it is obvious that an enormous sum could be usefully employed in the improvement of our national ways of communication, and that if only the most pressing of the work were done from 50 to 100 millions of national capital, or from £5,000 to £10,000 per mile, could be expended by engineers to very great national advantage.

Where power is available, either electricity or the cable must be adopted, and almost always electricity will offer most advantages. The steam-engine or the gas-engine being then the prime mover in the great majority of cases, the question arises what system of propulsion will give the most economical power on the rails, which will earn the greatest return on the capital outlay and give the lowest fares. It may be taken as fundamental that that system which employs the prime motor most directly upon the rails is the best from the economic point of view. From this it follows that were there no qualifying condition favouring less economical methods, the steam-car and the gas-engine car must, unhesitatingly, be chosen as the best.

The first qualifying condition which may be mentioned is the working of very steep inclines, and this favours the cable system.

For very confined situations, as in tunnel lines, the products of combustion of the fuel for steam raising or of the gas in gas-engines may be disqualifying attendants of these two forms of power on the cars. Under ordinary circumstances of level or nearly level street and suburban lines, the possibilities of the modern small high-pressure superheated steam-engine and of the gas-engine appear to place the independent car propelled by these motors in the most advantageous position. The electrical systems are open to the objection, firstly, that the prime motive power must first be converted into electricity and that electricity must be converted back into mechanical power. This at once raises the cost of the motive power on the rails by from 15 to 30 per cent., without considering any intermediate losses.

In past days when the large engines used in electric generating-stations could be shown to give an effective H.P. for much less steam than the smaller engines required on the independent steam-car this loss might not only be considered as more than covered, but the small engines and boilers available were also in many ways objectionable. This difference, however, has now been removed by the experience of the past few years with very high-pressure superheated steam, by means of which engines of less power than those required on tramcars are working with less steam per H.P. than the large engines of some of the large electricity generating-stations.

OBITUARY.

SIR HENRY BESSEMER.

ALL interested in mechanical science will learn with regret that the most distinguished metallurgist of the Victorian era has at length succumbed to the common fate of humanity and expired on the 15th ult., at the age of 85, at his residence at Denmark Hill, Surrey. Sir Henry Bessemer was known all the world over as the inventor of the Bessemer process of steel making, whereby common cast-iron was converted into steel. At the time that his invention was, after many trials and disappointments, perfected, steel was a very expensive article. Most steel was made by the cementation process, which was tedious and uncertain in its action. Bessemer's invention produced high grade steel of uniform quality at a ridiculously cheap rate. The economic advantages of this invention have been incalculable, as it rendered possible the cheap railway and steamship travelling of the present day. In other directions he was a successful and prolific inventor. Thus he invented the first type-composing machine, and a machine for embossing velvet. He was not always, however, successful in his inventions, as his swinging saloon testified. This saloon, or cabin, was intended to remain perfectly steady when fixed on board ships. A vessel, called the "Bessemer," was built for the purpose of testing it, but the thing was a complete failure. His steel factory at Sheffield brought him a very large fortune, and he was honoured everywhere as an inventor whose works have done so much to advance civilisation and to promote the welfare of the community.

The first recognition of Bessemer's work came from the Institution of Civil Engineers, in the shape of the gold Telford medal in 1859. In 1871-73 he was president of the Iron and Steel Institute, and founded a gold medal to be given annually for the most important improvement of the year in the manufacture of iron or steel. The Society of Arts awarded him the Albert gold medal in 1872, and in 1877 the Civil Engineers made him a member of their body, at the same time presenting him with the first Howard quinquennial prize. Two years later he became a Fellow of the Royal Society, and received the honour of knighthood, while in 1880 he was presented with the freedom of the City of London. He was also a freeman of the City of Hamburg, an honorary member and gold medallist of the Society of Arts and Manufacturers of Berlin, and a Grand Cross of the Order of H.I.M. Francis Joseph of Austria.

COLONEL DYER, R.A.

OF all those who in any way participated in the late disastrous engineers' dispute none stand out so prominently and so bonourably as Colonel Dyer, who, to the deep regret of masters and men alike, expired at Manchester on the 21st ult. Colonel Dyer was an artillery officer, and saw much active service in the Crimea. When retired he became superintendent at Enfield Gun Factory, and afterwards joined the firm of Whitworth and Co., of Manchester. On the amalgamation of this firm with that of Armstrong, Mitchell, and Co., Colonel Dyer became a director of the combination. He was in every way a most distinguished Englishman, combining the *suaviter in modo* with the *fortiter in re*. His talent lay in organising, and the skill he displayed in uniting the masters in a powerful Federation was marvellous. His tact and courtesy and justice in dealing with the demands of labour were equally conspicuous. So desirous was he of doing right in the late great struggle that he worked unduly hard to this end, and his regretted death was the consequence.

The Automobile Club of Belgium.—As will be seen from the letter which we publish elsewhere in our present issue, Sir David Salomons, Bart., the respected President of the S.P.T.A., is exerting no little influence for the encouragement of automobilism on the Continent. He has offered the handsome prize of 500 francs to the Committee of the Belgian Automobile Club, to be awarded to that competitor in the forthcoming Concours on June 25th and 26th who produces the best—that is, other things being equal, the most elegant, comfortable, and well-appointed—vehicle. In contributing this prize Sir David Salomons is rendering a distinct service, as improvement in the directions indicated is much wanted. We have, it is true, the London electrical cab, for example, which, while not exactly a model of ugliness, might yet be very much improved. Even the most favourite type of voitures leave much to be desired in the matter of elegant design, to say nothing of the uncomfortable vibration with which so many of them are afflicted. We trust that, inspired by this example, builders will endeavour to evolve a design which, while satisfying the mechanical requirements, will also gratify the by-no-means unimportant æsthetic ideal.

SELF-PROPELLED TRAFFIC ASSOCIATION

(INCORPORATED).

LIVERPOOL CENTRE.

The Arrangements for the May Trials.*

THE object of this paper is to acquaint members of the Association, subscribers to the Trials Fund, and others interested in this branch of the Association's work, with the programme of the trials so far as the same may yet be divulged. It is hoped that it may provide a convenient means of circulating an outline of the arrangements at a date which will give ample time for interested parties to decide to attend the trials and to advise the Association of their intentions. The trials will begin on the morning of Tuesday, May 24th, 1898, and will conclude on the afternoon or evening of the Friday following.

By way of introduction it may not be out of place to remind you of the condition laid down in the "Particulars of Competition" whereby the minimum load consistent with the qualifying adjective "heavy" is stipulated as 2 tons. This regulation has had the not altogether unexpected effect of debarring from competition all vehicles propelled by internal combustion engines or oil-motors, the several constructors in this country having intimated that they consider 1 ton of goods to be the useful and satisfactory limit of load in the present stage of development of this particular form of prime mover. Whilst, therefore, of no practical value for our normal traffic, oil-propelled parcel-vans and light lorries will, in all probability, render a good account of themselves at the trials of the Royal Agricultural Society in June next.

Another of the regulations which has been subjected to adverse criticism is the one which imposes minimum average speeds of six and four miles an hour in Classes I and II respectively, the contention having been that an average of six miles an hour is too great a speed to guarantee with a load of, say, 4½ tons. After full consideration the Council, in order to encourage motor traffic and to give every scope for originality in design and construction, decided to allow vehicles to be entered in a third class, in which the only special regulation is:—"That the vehicle shall carry a minimum load of 2 tons during the trial runs."

Before proceeding to the list of entries it is desirable to touch upon the "weeding out" process that has been apparent as regards builders who at one time purposed taking part in the trials—the

* Excerpt of paper read before the Liverpool Centre of the Self-Propelled Traffic Association, by Mr. E. SHRAPNELL SMITH, Hon. Local Sec., on April 14th, Mr. Jas. A. Brodie, M. Inst. C.E., in the Chair.

names, it is scarcely necessary to add, are safe in the secrecy of secretarial confidence. At the beginning of January communications were addressed to about 60 firms of engineers engaged in the construction of self-propelled road vehicles, traction engines, agricultural machinery, &c. By way of acknowledgment some of the firms simply stated that they were not prepared to go into the matter, others pleaded that pressure of work for standard types prevented their building for the trials, and more than one regretted that the engineers' strike had most seriously interfered with their experiments and private trials. The replies received are, taken as a whole, of great interest, and serve to indicate that there already exists amongst our foremost engineers the good intention at least to apply their experience to the evolution of satisfactory motor-wagons for heavy loads. The net result of these inquiries led to the conclusion that we should have at least 12 British competitors taking part in the trials, but the appended list will show that the makers' estimates were too sanguine, for we have received entries from only six intending competitors, who have entered 10 vehicles.

ENTRIES.

CLASS I.—*Minimum load, 2 tons; minimum average speed, 6 miles an hour; minimum platform area, 60 square feet.*

Official No.
7 T. Coulthard and Co., Cooper Road, Preston.
9 Robert Cooke Sayer, 11, Clyde Road, Redland, Bristol.
1 The Liquid Fuel Engineering Company, 20, Abchurch Lane, London, E.C.
2 The Steam Carriage and Wagon Company (Limited), Homefield, Chiswick, London.

CLASS II.—*Minimum load, 5 tons; minimum average speed, 4 miles an hour; minimum platform area, 110 square feet; floor of platform to be not less than 3 feet 9 inches, or more than 4 feet 3 inches, from ground.*

Official No.
3 The Steam Carriage and Wagon Company (Limited), Chiswick.

CLASS III.—*Minimum load, 2 tons.*

8 T. Coulthard and Co., Preston.
10 Robert Cooke Sayer, Bristol.
5 The Lancashire Steam Motor Company, Leyland.
6 The L. R. Syndicate (Limited) (Serpollet System), 22, Chancery Lane, London, W.C.
4 The Steam Carriage and Wagon Company (Limited), Chiswick.

Electricity is unrepresented. The gentleman who, some twelve months ago, offered to carry 1,000 tons of goods weekly in 10 ton units, by means of accumulators at 2*d* per ton mile, is evidently still engaged upon the problem—or has given it up. However, seeing that the motors being made for the Paris electrical cabs give 8½ B.H.P. for 20 minutes, or 4½ B.H.P. in continuous running, without undue heating, and weigh only 170 lbs. each, there appears to be an opening for the application of one such to each wheel of a lorry. Taking the secondary battery of to-day as weighing 1½ cwts. per B.H.P. given off by the motor on a five hours' discharge, there is every reason to look for a commercial vehicle fitted with one large battery and constructed to use several motors as required.

It will be noticed that no entries have been received from French constructors. We had hoped for several, but the limit of 3 tons tare imposed by the Light Locomotives Act, 1896, has put all the Continental vehicles out of the competition. Some of the largest firms in France have been in correspondence with the Association, with respect to their taking part, if possible, and the Association has been reluctantly compelled to send a negative reply in every instance.

This opportunity is too good a one to be passed over, without an expression of regret that the framers of our Act thought it necessary to place a limit upon the tare of the vehicle. The existing maximum of 3 tons tare practically prohibits the construction of vehicles with platforms such as we require for much of our Liverpool work. It does not make one iota of difference, so far as the maintenance of road-surfaces is concerned, whether the weight is all tare or part tare and part freight, and the demand for commercial efficiency is a sufficient spur to constructors to keep the tare as low as possible. If, therefore, a limit there must be, let it be placed upon the total moving weight, or upon the total weight per axle.

Sufficient information has not yet been returned to justify the inclusion in this paper of any descriptive details, even were it desirable or expedient to publish the same at this juncture, as the "Lists of Particulars" may be lodged by competitors any time up to the 16th proximo. It is probable, however, that, as the practical tests to be applied during the trials are sure to be of infinitely greater value than the mere statement of theoretic points, none will resent the request that they wait till May 24th, and then judge for themselves.

The majority, if not all, of the vehicles entered are steam-propelled with oil-fired boilers, ordinary paraffin (sp. gr. about 0·800) being the fuel used. One of the vehicles is fitted with a boiler of the so-called "instantaneous generation" or "flashing" type.

The trials will open at nine o'clock on the morning of Tuesday, May 24th, with an inspection by the judges at the depôt to be used as the point of departure and arrival during the trials. Mr. Alfred L. Jones, vice-president, has very kindly offered to put Gregson's Mill, Caryl Street, at the disposal of the Association for this purpose, and his offer may be taken advantage of. In any case, the depôt will be in Liverpool, and it is hoped that the Mersey Docks and Harbour Board will grant the use of their yard at the south-west corner of the Prince's Dock. This position is very central, being right at the foot of Chapel Street.

The first vehicle will start from the depôt shortly after nine o'clock on each of the four days, and the others will follow at intervals of about ten minutes. Each vehicle will display its official number and carry an official observer appointed by the judges. It will be noticed—and possibly objected to by some—that an early start is to be made, but such a procedure is very necessary. If, say, in the case of a wagon carrying a 5-ton load, the speed attained averages only four miles an hour, on a 36-mile route, the journey will occupy nine hours. In order, therefore, that those following the competition may get back to Liverpool not later than 7 p.m., it is intended to despatch the heavier vehicles first and to endeavour to send the last away before 10.30 a.m.

Routes.

The conditions require that the routes shall not be announced until the date of the trials. At present it can only be stated that two routes have been selected which come within the prescribed limits—between 30 and 40 miles—and that, presuming eight only to be presented for trial, four vehicles will be put upon each route, two in each direction. Thus, when the runs are completed, each competitor—breakdowns, if any, excepted—will have traversed each route in each direction.

Sketch maps will be prepared and issued as stated, and it will then be found that the routes chosen are so arranged as to permit parties following the competition to cross between them at various points. The question of supplying fuel and water *en route* is receiving proper attention.

Visitors.

Formal invitations have been addressed to the Automobile Club de France, the Automobile Club Belge, the War Office, the Post Office, the Board of Agriculture, the Local Government Board, and other Government Departments.

We hope to see a number of the members of the French Club, including Baron Zuylen (President), Comte de Dion (Vice-President), Comte de la Valette, M. Pierre Giffard, M. Amédée Vernes, Baron Rogniat, M. Andre Michelin, and M. G. Forestier (Government Inspector of Roads and Bridges), but the complete notifications have not yet arrived. The Belgian Club has not, so far, acknowledged our invitation.

The Postmaster-General has instructed the Liverpool Postmaster to attend and report upon the trials. But singularly enough the Board of Agriculture does not intend to be represented at them.

The War Office have not yet replied beyond the first acknowledgment, but as the Royal Engineer Committee of this Department have recently appointed a sub-committee of their members to consider the adaptability of motor-vehicles for military transport, there is reason to expect that they will not allow the Post Office to monopolise the advantages to be derived from attendance at the trials. We are in correspondence with the Board of Agriculture and the Local Government Board, and other public departments, and the nature of their replies will be published in the next issue of our official journal.*

The Association will shortly issue invitations to a number of colonial representatives, mayors, chambers of commerce, merchants, engineers, and others likely to be interested to attend the trials. Intending visitors are recommended to engage rooms in advance to avoid disappointment, and in every case to notify the Association of

* *i.e.*, THE AUTOMOTOR.

the date on which they will arrive, the duration of their visit, and their address during the trials.

The headquarters of the Association will be at the Adelphi Hotel.

Owners of light self-propelled carriages are invited to bring them to Liverpool, as they will find them an advantage and convenience. The Association has arranged for the housing of such light vehicles at a central position convenient to the principal hotels.

Entertainment.

The members of the Liverpool Council will take every care of visitors. The nature of the competition does not permit of any definite programme, especially as the week ends with the Whitsuntide holidays; but all facilities will be afforded to any who desire to visit or inspect particular objects or places of interest connected with the city or port of Liverpool.

A Dinner will be held at the Adelphi Hotel, on a date embraced by the trials. As soon as the date is fixed, notices will be issued.

Exhibition of Vehicles.

In deference to a widely-expressed wish, the Council are considering the expediency of holding a short public exhibition of the vehicles after the trials. If it is decided to do so, the arrangements will be announced at as early a date as may be convenient.

Finance.

The subscriptions and entry fees combined now amount to close upon £500, and it is probable that £600 will be reached. We originally sought to secure £750, which amount was to include the expenditure in bringing across vehicles from the Continent, and to leave ample margin for contingencies. Since, however, as mentioned above, legal restrictions preclude the possibility of our having the pleasure of seeing any French vehicles, a considerable item is expunged from the estimates, and our financial position is perfectly satisfactory.

A special account has been opened with Messrs. Leyland and Bullins, under the title, "The Self-Propelled Traffic Association Trials Account." Accounts, duly audited, will be issued to members and subscribers as soon as practicable after the trials, and, should the amount collected prove to be in excess of the expenditure, the surplus will be returned to the subscribers *pro rata*.

By way of comment upon the donations given, it may here be remarked that Liverpool traders have not supported the Association as generously as the occasion warrants, it being left for comparatively few to provide the necessary funds.

Judges.

The following Members of Council were elected in February last:—

London Council: Sir David Salomons, Bart.; Mr. Boverton Redwood, F.R.S.E., F.I.C.

Liverpool Council: Mr. John A. Brodie, M. Inst. C.E.; Mr. Everard R. Calthrop; Prof. H. S. Hele-Shaw, LL.D., M. Inst. C.E.

Reserves: Mr. B. Cottrell, M. Inst. C.E.; Mr. Henry H. West, M. Inst. C.E.

Mr. Brodie has intimated that his duties as city engineer prevent his accepting any appointment which would involve such a demand upon his time, but that he will be pleased to do anything he can to make the trials a success. Mr. Cottrell will act in place of Mr. Brodie.

Vehicles.

Although the definite dimensions laid down by the Council in framing the rules somewhat prescribe the types that can be represented at the trials, it must be remembered that the interest taken in the competition will not be limited to those who wish to convey heavy loads of goods. The competing vehicles cannot fail to be of considerable interest for the purposes of heavy passenger traffic, as it is the class of body fitted—not the framing or machinery—that determines the use to which the vehicle shall be put. As a matter of fact, tipping-bodies, platforms, van-covers, sideboards, and numerous variations of superstructure, are applied to one and the same frame by several builders at the present time.

Before concluding this paper, it is worthy of remark that 69 years ago there was held in this neighbourhood a competition for locomotives on rails, at which the world-famed "Rocket" out-distanced all competitors. Whether the trials now being organised by the Liverpool Centre of the Association will bring to light the "Rocket" of self-propelled road vehicles remains to be seen. It is, perhaps, too much to expect that equally far-reaching advantages will be derived from the present effort, which, nevertheless, has involved no little work so far and may involve very much more before the competition is over. The Association may reasonably, in any case, congratulate itself that, of all the large centres of commerce in this country, Liverpool has proved to the fore, as in the past it did in the railway movement, in giving encouragement to a new movement which is calculated to improve, or possibly to perfect, the existing means of transport and thereby to confer a benefit upon the whole of the community.

TRIALS FUND.

The following subscriptions have already been remitted or promised:—

Steel Springs for Motor-Cars.*

IN speaking on the subject of springs for motor-cars I do not propose to go into the past history of the development of springs from the time when our forefathers were satisfied with the leather straps for carrying the bodies of carriages and other vehicles. I therefore pass directly to the kinds of spring used for railway rolling stock, roadway, and other purposes, now in general use.

The steel used for all descriptions of springs is made by the following processes:—

1. Bessemer—Acid steel.
2. Martin Siemens—Acid steel.
3. Converted Swedish iron bars.
4. Swedish Bessemer steel.
5. Crucible steel.

The steel in general use for railway engines, carriages, and wagons is made by the acid processes (Nos. 1 and 2), and as springs made

* Excerpt of a paper read before the Liverpool Centre of the Self-Propelled Traffic Association, on March 22nd, by Mr. J. BEDFORD of Sheffield.

from this steel are in general use for carrying the above-mentioned heavy rolling stock, it is quite safe to assume that springs made of the same class of steel will prove equally satisfactory for motor-cars for carrying any weight of load. Steel made by the processes Nos. 3, 4, and 5 are much more costly, and their uses are chiefly confined to the finer and more delicate class of springs, such as safety valves, watch springs, and also for landaus and light carriages.

The following is a brief outline of the method of producing bars suitable for making all kinds of springs for railway and other heavy springs:—When the hematite iron has passed through its operation, either in the Bessemer converter or the open hearth furnace to the finished steel, it is cast into ingot moulds, in varying weights from 10 cwt. upwards. These ingots are cogged into blooms, and the blooms rolled down as required for the various-sized plates, the carbon content in the steel varying from ·45 to ·60 per cent. for laminated, and from ·60 to ·90 per cent., and even 1·0 per cent. for spiral, conical, and volute springs.

The following is the analysis of acid steels used for laminated springs for all railway purposes, and steel of the same analysis will be found suitable for carrying any required loads on motor-cars:—

Analysis of Bessemer Acid Steel for Laminated Springs.

Carbon	·45 per cent. to	·60 per cent.	
Silicon	·03 „	·06	„
Manganese ..	·75 „	1·00	„
Sulphur	·03 „	·05	„
Phosphorus ..	·03 „	·05	„
Iron	By difference.		

Analysis of Martin Siemens' Open Hearth Acid Steel for Laminated Springs.

Carbon	·50 per cent. to	·65 per cent.	
Silicon	·03 „	·05	„
Manganese ..	·35 „	·60	„
Sulphur	·03 „	·05	„
Phosphorus ..	·03 „	·05	„
Iron	By difference.		

It is impossible to lay down a hard and fast line as to the absolute mechanical tests of steel suitable for laminated springs in the range of carbons given, but the following may be taken as the approximate tests of spring steels in the normal condition. By the words "normal condition" is meant the steel in the state as rolled down into plates or bars while hot, before being hardened and tempered:—

Bessemer Steel.

Carbons.	Tensile strains per square inch.	Elongation in 3 inches.
·45 per cent.	50 tons.	20 to 25 per cent.
·50 „	54 „	
·55 „	56 „	
·60 „	58 „	

Open Hearth Steel.

Carbons.	Tensile strains per square inch.	Elongation in 3 inches.
·50 per cent.	50 tons.	22 to 27 per cent.
·55 „	53 „	
·60 „	55 „	
·65 „	56 „	

Although these spring steels in their normal conditions show these mechanical properties, it will be well understood that it is impossible to give any formulæ of the same mechanical properties when the steel is in the hardened and tempered condition ready for fitting in the springs; as these properties will necessarily vary with the degree of tempering given to the finished plates. It would no doubt be extremely valuable if a formula could be arrived at for getting a uniform strength of steel in the hardened and tempered condition, but it is not possible to give this on account of the variations arising from the tempering of the plates.

Assuming, however, the chemical elements of the steel to be represented by the analyses given and also that the plates are uniformly hardened and tempered and accurately fitted, the following rlues (as published in Molesworth's Pocket-book) for estimating the strength of laminated springs will be found approximately correct. Let—

S = Span of spring in inches.
B = breadth of plates in inches.
T = Thickness of plates in sixteenths of an inch.
N = Number of plates.
D = Deflection in inches per ton of load.
L = Safe load on springs.

Then—

$$L = \frac{B\ T^2\ N}{11{\cdot}3\ S}$$

$$N = \frac{11{\cdot}3\ S\ L}{B\ T^2}$$

$$D = \frac{{\cdot}14\ S^3}{T^3\ B\ N}$$

Spiral springs are also made for carrying heavy loads, and if the design of the motor-cars admits of sufficient space for the larger base or bearing surface required it may be, in some cases, advisable to adopt this pattern of spring. Spiral springs are not infrequently built up in nests, as shown in Fig. 2, that is to say, one spring is inserted inside the other, usually to about three in number. These spiral springs, or nest springs, are mostly used on bogie wheels for heavy vehicles, such as the bogie wheels on engines, Pullman cars, &c. Many users of springs object to the conical-shaped springs (*see* Fig. 5) on account of the danger that might arise from the buckling of the spring.

I am indebted to Messrs S. Fox and Co. (Limited), Stocksbridge Steel Works, Sheffield, and Messrs. Ibbotson Bros. and Co. (Limited), Globe Steel Works, Sheffield, for the samples of springs I submit to this meeting. These springs are made from acid steel. Before the plates in the laminated springs were worked into shape, a portion of one plate was tested in the ordinary manner with the following results:—

Tensile strain	55 tons per sq. in.
Elongation, percentage in 3 inches ..	20 per cent.
Contraction of area at point of fracture with test piece	30 per cent.

The large, laminated spring made by Messrs. Fox and Co. (*see* Fig. 1) has been specially built for carrying a heavy load.

Length from centre to centre of holes in the straight, 4 feet.

Eight plates 3½ inches by ½ inch.

Top plate has solid eye, and is drilled to Whitworth gauge with 1-inch diameter hole for pin.

Each plate is properly fitted, ribbed and slotted to prevent the lateral disarrangement of the plates.

Cambre, 5⅜ inches.

The ultimate load of the spring is 7 tons.

The average deflection under load is ·729 inch per ton.

The deflection per ton on this spring is as under:—

	At Rest.	1 *Ton.*	2 *Tons.*	3 *Tons.*	4 *Tons.*	5 *Tons.*	6 *Tons.*
	ins.	ins.	ins.	ins.	ins.	ins.	ins.
Cambre	5⅜	4½	3⅜	3	2¼	$1\frac{7}{16}$	¾

The spring has been tested in the scrag or testing machine, and brought down ¾ inch beyond the straight 14 times. It has returned to its original cambre without showing any permanent set or injury whatever.

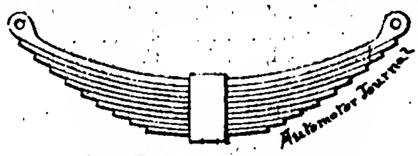

Fig. 1.—Forged Solid Eye Spring.

I have here springs of various patterns for carrying various loads. These represent standard springs in general use on English, Indian, Colonial, and various foreign railways. The springs have not been specially made for exhibition, and may be taken as representative of springs as made day by day in fulfilment of running contracts.

The tests of the springs as given in this paper are truly representative of the carrying powers of the several springs shown. All the tests have been obtained from the springs now exhibited. Springs of the various designs for carrying lighter and heavier loads than given are of course regularly made:—

List of Springs Shown.

		Ultimate Load of Spring.
No. 1.	Laminated spring made by Messrs. S. Fox and Co. (Limited), Stocksbridge Steel Works, Sheffield (Fig. 1)	7 tons.
No. 2.	Single spiral spring, also made by Messrs. S. Fox and Co. (Limited) .. .. .. (Giving a regular resistance of 32 cwts. for each 1 inch of deflection.)	5 „

The following springs have been kindly lent by Messrs. Ibbotson Bros. and Co. (Limited), Globe Steel Works, Sheffield :—

		Ultimate Load of Spring.
No. 3.	Laminated spring	2 tons.
No. 4.	Triple nest of coil springs (Fig. 2) ..	5 „
No. 5.	Single spiral spring (Fig. 3)	4 „
No. 6.	Single spiral spring of round steel ..	2 „ 8 cwts.
No. 7.	Volute spring (Fig. 4)	4 „
No. 8.	Conical spring of oval spring (Fig. 5) ..	4 „

The following are the leading particulars of these springs :—

No. 2. Single Spiral Spring—

Dimensions :
- 6¾ ins. high.
- 5 ins. diameter.
- 2¼ ins. hole.
- 6 coils.
- Steel, 1⅜ ins. by ⅞ in.
- Resistance, 1 ton 12 cwt. for each 1 inch of deflection.
- Ultimate resistance, 5 tons.
- Weight of spring, 22 lbs.

This spring is very extensively used on one of the Indian railways.

No. 3. Laminated Spring—

Length from centre to centre of eye	3 ft. 8½ ins.
Length under 2 tons load, namely, when straight	3 ft. 9 ins.
Cambre, free to centre of eyes	3 ins.
Cambre, under 1 ton	1⅜ ins.
Cambre, under 2 tons	Straight.
Weight of spring	3 qrs. 5 lbs.

The spring is built up as follows :—

1 back plate, 3½ ins. by 7/16 in.
8 other plates, 3½ ins. by ⅜ in.

In the laminated springs exhibited, the plates are temporarily held together by a nut and bolt, but in actual practice a buckle or hoop is always required for the fixing of the spring to the axle-box.

No. 4. Triple Nest of Coil Springs, made up as follows (Fig. 2)—

Fig. 2.—Nest of Spiral Springs.

			Section.
	ins. ins. ins.		ins. ins.
Outer spring ..	7⅞ × 6¼ × 5⅜, 4 coils, full tip to tip.		1¼ × 9/16.
Inner spring ..	7⅞ × 5¼ × 4¼, 5 coils, bare tip to tip.		1⅛ × ½.
Centre spring ..	7⅞ × 4⅜ × 3¼, 5½ coils, tip to tip,		1 × 7/16.

Total weight of springs, 28 lbs.

This nest has been tested with the following results :—

	Free	1	2	3	4	5 tons.	Home.
Inches ..	7⅞	7¼	6¾	6 1/16	5½	5⅛	5

This is the class of spring already referred to as used under Pullman and similar cars, in conjunction with elliptical or laminated springs.

No. 5. Single Spiral Spring of Rectangular Section (Fig. 3)—

Fig. 3.—Spiral Buffer or Spring.

Dimensions :

7¼ ins. high.	8 coils, tip to tip of steel.
4½ ins. diameter.	Section of steel, 1 3/16″ × ¾″.
2¼ ins. hole.	Weight, 15¼ lbs.

The following results have been obtained by actual test :—

	Free.	1	2	3	4 tons.	Home.
Inches	7¼	6⅝	6 3/16	5¼	4⅝	4¼

No. 6. Single Spiral Spring of Round Steel—

Dimensions :

6 ins. high.	6 coils, tip to tip of steel.
4½ ins. outside diameter.	Steel, ¾ ins. round.
2¾ ins. hole.	

	Free.	1	2 tons.	48 cwts.	Home.	Weight.
Inches ..	6	5	4¼	4	3 15/16	6¾ lbs.

No. 7. Volute Spring (Fig. 4)

Fig. 4.—Volute Spring.

Dimensions :

9½ ins. high.	2 ins. hole.
6 ins. base.	Steel, 4½ ins. by 7/16 in.

	Free.	1	2	3	4 tons.	Home.	Weight.
Inches ..	$9\frac{1}{8}$	$8\frac{1}{16}$	$6\frac{13}{16}$	$5\frac{9}{16}$	$4\frac{3}{4}$	$4\frac{1}{4}$	22 lbs.

No. 8. Conical Spring (Fig. 5)—

FIG. 5.—CONICAL SPRING.

Dimensions:
6 ins. high. $1\frac{5}{8}$ ins. hole.
$7\frac{1}{4}$ ins. base. Oval section, $1\frac{3}{8}$ ins. by $\frac{9}{16}$ in.

	Free.	1	2	3	4 tons.	Home.	Weight.
Inches ..	6	4	3	$2\frac{1}{8}$	$1\frac{3}{4}$	$1\frac{5}{8}$	$13\frac{1}{2}$ lbs.

[*A paper by* Mr. J. T. NIBLETT, M. Inst. E.E., *read on March 29th before the Liverpool Centre of the Self-Propelled Traffic Association, will be found on p.* 255.]

Commendable Enterprise.—On March 25th a meeting was convened in the Court House, Stowmarket, by the leading inhabitants and tradesmen to consider the desirability of connecting Stowmarket with the surrounding villages by means of a service of motor-vehicles. Mr. Holley presided. Particulars respecting the advantages of different kinds of motor-vehicles were given by Mr. Julius Harvey, of Mansion House Chambers, London, who, having conveyed Her Majesty's mails for some thousands of miles successfully, was able to give accurate and interesting statistics. He also exhibited photographs and drawings of vehicles running in other towns. The scheme was supported by a large majority of those present, who promised to take a pecuniary interest in the venture.

Narrow v. Broad Tyres.—Narrow tyres for vehicle wheels have long been popular in America, but some recent elaborate experiments carried out at the Missouri agricultural station go to show that the practice has little or nothing to recommend it, the tractive force necessary to propel a wagon being usually much increased thereby. Thus, on a macadam road it was found that a load of 2,518 lbs. could be hauled with the same tractive effort as was needed for a load of 2,000 lbs. with narrow tyres. On a gravel road, except when the surface was very wet and sloppy, similar figures were registered, six trials showing that with broad tyres a load of 2,482 lbs. could be hauled as easily as one of 2,000 lbs. with narrow tyres. With dirty roads the results varied according as the surface was wet or dry. When firm, hard, and free from dust, a load of 2,530 lbs. on broad tyres required no more hauling effort than one of 2,000 lbs. with narrow tyres. When the road was very loose and dusty, however, the narrow tyres had the advantage, and with clay roads the same was the case when the surface was sticky on top and firm below; but when deep in mud and drier on top, or dry on top and spongy below, the reverse was the case, the broad tyre showing an economy of 52 to 61 per cent. in the tractive power necessary. Off the road, and in pasture, meadow, stubble land, or corn ground the broad tyre proved much superior to its rival. As a result of the experiments it was settled that 6 inches was about the best width of tyre for a combination road and farm wagon, and, further, that in four-wheeled wagons the hind wheels should run in the same track as the leading ones.—*Engineering.*

PETROL STORES.

WE have received so many enquiries as to where petrol can be obtained throughout the country that we have very much pleasure in publishing hereunder a first list of firms who stock this oil and other accessories needful for automobilists:—

ALTON—Hetherington and Son, ironmongers.
ANDOVER—T. Lynn, ironmonger.
ASHFORD, Kent—J. Broad, 24, Park Street.
BASINGSTOKE—Julian and Sons, Church Street.
BRIGHTON—Brighton Cycle and Motor Co. (Ltd.), 9, Marine Parade.
CANTERBURY—Court Bros, 12, Butchery Lane.
CHICHESTER—A. Ballard, 7 and 8, East Street.
COLCHESTER—Kent, Blaxill, and Co., 102, High Street.
DORKING—C. J. Peirson and Co., 22, High Street.
Stone and Turner, 98, High Street.
DOVER—M. Pepper, High Street.
DUNSTABLE—H. Brown, 6, High Street.
EPPING—Wm. Cottis and Sons.
FAREHAM—H. Clark, ironmonger.
FARNHAM—M. and J. Tily, Castle Street.
J. H. Knight, Barfield.
FOLKESTONE—W. Francis, 66, High Street.
GUILDFORD—R. Shillingford and Co., 135, High Street.
Lawes and Co., Bridge Street.
HERTFORD—J. Cooper and Sons, 13, 15, and 21, Maidenhead Street.
HUNTINGDON—R. W. Cater and Son, 95, High Street.
LANDPORT—Wm. Smith, 316, Commercial Road.
LEIGHTON BUZZARD—S. Cooper, 14, Market Square.
LEWES—J. Broad and Sons.
LITTLEHAMPTON—Ockenden Bros., High Street.
MAIDENHEAD—Thompson and Walton, chemists.
MAIDSTONE—E. Allcorn and Co., 30, Stone Street.
NORTHAMPTON—Johnson and Wright, Gold Street.
OXFORD—R. Foort, 19, Queen Street.
READING—J. H. Fuller, 50, Minster Street.
RYDE—Geo. Turner, 134, High Street.
SAFFRON WALDEN—Robson and Sons, Freshwell Street.
SEVENOAKS—G. Humphrey, 166, High Street.
SITTINGBOURNE—H. Penteny, 21, East Street.
SOUTHAMPTON—J. G. Fay and Co., 80, High Street.
Summers and Payne, Belvedere.
SOUTHSEA—S. Rose and Co., Castle Road.
ST. ALBANS—R. Norman, Victoria Road.
ST. IVES—Turner and Sons, chemists.
TONBRIDGE—Wightwick and Son, High Street.
TUNBRIDGE WELLS—J. Willmot, 16, High Street.
WINCHESTER—H. W. Frampton, 1, Jewry Street.
WINDSOR—W. H. Brooks and Sons, 28, Peascod Street.
WOODBRIDGE—R. H. Rowland, hardwareman.
WORTHING—Thos. Page, 3, South Street.

Brighton Objects to Motor-Cars.—The Brighton Cycle and Motor Company (Limited) applied last week for a license for a motor-car to run to Rottingdean, Shoreham, and Patcham, from a station in the open space on the Old Steine. The Watch Committee have resolved that the application be not complied with, which decision the Council duly endorsed. It would be interesting to know on what grounds the Council object.

AT the Clacton District Council last week a letter from the London Motor-Van and Wagon Company (Limited) was read, stating that they were proposing to place motor pleasure carriages at various seaside resorts, and Clacton had been suggested as a suitable town to commence with. It was proposed at Whitsuntide to start four carriages, capable of carrying eight passengers each. These carriages would ply for hire, with the permission of the Council, which they now asked. The matter was referred to the Improvement Committee.

THE AUTOMOTOR

AND

HORSELESS VEHICLE JOURNAL

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

Circulates amongst Makers and Users of Motor-Cars, Cycles, etc., in the United Kingdom, the Colonies and the Continent.

VOL. II. No. 20. MAY 16TH, 1898. PRICE SIXPENCE.

CONTENTS.

THE FULMEN STORAGE CELL FOR MOTOR-VEHICLES.

THAT distinguished electrical engineer, M. Hospitalier, is contributing a series of most valuable articles on electromobiles to the pages of our esteemed contemporary, *La Locomotion Automobile.* In a recent issue he describes the Fulmen cell, and as this is deservedly very popular on the Continent, a description of it will be of interest to our readers, as they will thus be able to make a comparison between it and others. Says M. Hospitalier, whom we render freely:—

We know that the accumulators intended for electrical motors ought to present, as primordial qualities, a large specific power (watts per kilogramme of total weight) and a great specific energy (watt hours per kilogramme of total weight), in order to permit the reduction as much as possible of the dead weight carried and to thus increase the length of the route traversed which the battery permits without recharging.

These propositions are to-day well established for a certain number of types of accumulators, and we have personally had the opportunity, at the electrical laboratory of l'Ecole de Physique et de Chimie Industrielles de la Ville de Paris, to follow experimentally, step by step, the progress made by the appliances for storing electric power during the past 15 years, and in particular the Fulmen accumulator used in France by M. Jeantaud and M. Kriéger.

Owing to the kindness of M. Brault, the managing director of the Fulmen Accumulator Company, we have been able to completely study a type of element (cell) specially arranged for vehicles, and carefully noted its construction and working.

The type we have tried is known as Type B, and comprises 13 plates (6 positives and 7 negatives). The rectangular plates are 18·5 centimetres high, 9·5 centimetres wide, and 4 millimetres thick. They form a square of 24 rectangular cells, in which are deposited the active matter. Thin strips of perforated celluloid prevent the plates from coming into contact.

The wet plates, cut close to the attachments, have given us the following weights respectively of the grating (or divisions) and of active matter in grammes:—

	Positive Plates.	Negative Plates.
Grating (or Divisions)	135	135
Active Matter	340	255
Total Weights..	475	390

The area of each plate is 1·75 decimetres, which corresponds to 21 decimetres of total area for the 12 areas of the six positive plates. The box (in celluloid) and the separation of the plates weigh 600 grammes.

The total weight of the complete element with the liquid is 7·5 kilogrammes = 16·5 lbs.

M. Brault considers the normal rate of discharge to be a current of 21 ampères, corresponding to a continuous discharge in five hours, say, a density of current of 1 ampère to the square decimetre of the area of the positive plate, but the accumulator can supply at the cost of its capacity as much as 50 ampères in continuous discharge and as much as 100 ampères on a short circuit.

At the normal discharge in five hours the average difference of the potential of the element is about 1·9 volts and the capacity about 105 ampère hours. Each element of 7·5 kilogrammes has an output of 40 effective watts, and retains a disposable energy equal to 200 watt hours.

The detailed particulars of the element reduced to total weights are as follows:—

The specific output in ampères ..	per kilogramme	3
Useful specific power in watts ..	" "	5·3
Specific capacity in ampère hour	" "	14·6
" useful energy in watt hour	" "	26
" weights in kilogrammes ..	per kilowatt	190
" weights in kilowatt hour ..	.. ..	37·5

At the rate of 5 watts per kilogramme, the Fulmen accumulator retains, then, more than 25 watt hours per kilogramme. These two figures are sufficient to calculate the weight of accumulators necessary to work an automotor of a total given weight, at a given speed, and upon a given road, knowing the yield of the motor and of the transmission as well as of the route it has to travel between two successive charges.

If one doubles the rate of specific continuous discharge, and one brings it to 10 watts per kilogramme, the specific energy lowers to 20 watt hours per kilogramme. If it does not want more than 100 kilogrammes of accumulators to produce 1 kilowatt, it will consequently need 50 kilogrammes (instead of 40) to store up per 1 kilowatt hour. If, on the contrary, one reduces by half the specific rate of continuous discharge, the disposable specific energy increases, and reaches 30 watt hours per kilogramme.*

It must then be remembered, in calculating the weight of a battery, that you lose in energy what you gain in power, and, inversely, that the accumulators keep much better in proportion if submitted to a more moderate rate of discharge.

In the special application with the vehicle accumulator, the discharge is not continuous, but, on the contrary, extremely variable, and the intervals of alternate action and rest are favourable to the diffusion of the liquid, a diffusion that is equally brought about by the agitation of the elements during the run. The figures indicated for the normal rate can then be accepted as representing really the available energy in spite of the variations of the output.

With regard to the duration of the elements, we cannot give a figure for this because the conditions of the working of the accumulators in the laboratory and on the route differ too much. The working of motor-vehicle accumulators will soon bring us the information wanted on this important point.†

We had intended to publish the mode of working other types of accumulators used for automotors, when we discovered that they were nearly all too greatly inferior to those we have just been giving for the Fulmen accumulator. As each maker or inventor claims for his apparatus advantages of solidity, durability, cheapness, and easiness of putting together, &c., which compensates more or less for the inferiority of the output and capacity, it seems to us best not to pave the way for any claims and vindications.

The figures which we have given, and which are the result of our personal experience, represent the maximum of what one can obtain with the present accumulators. In waiting for better, and in spite of the proverb which says that "better is the enemy of good," the question of the accumulators is studied a little everywhere to-day, and we agree to think that the present maximum is but very provisory. Such as it is to-day, it is sufficient, however, to produce practical motor-accumulators capable of running daily over a track of from 50 to 60 kilometres without recharging.

THE PRÉTOT MOTOR-VEHICLE.

Among other types of motor-vehicles which are bidding for public support the Prétot stands a good chance of obtaining a fair share of patronage, in that it enables ordinary four-wheel vehicles of the usual construction to be easily and inexpensively converted into motor-vehicles. The principle adopted is well known to most of our readers, but for the benefit of others we may say that the Prétot system consists in mounting a motor and its accompanying gear on a two-wheeled axle, the whole being placed under the forepart of any ordinary carriage or cab, replacing the ordinary wheels. The system has much to recommend it, as the connection can be so easily made. An ordinary four-wheeled cab or tradesman's cart could in the course of a couple of hours' work be readily converted into a motor-vehicle. Little alteration is required: all that has to be done is to disconnect the front axle and its gear and connect with the Prétot. The footboard has to be cut in two places, to enable the starting lever, steering gear, &c., to be placed within convenient reach of the driver's hands. As regards the mechanism, this consists of a pair of horizontal cylinders placed nearly opposite each other and working on the usual Beau de Rochas cycle, that is, in each cylinder there is an explosion at every second revolution. Hence, in this motor there is an impulse for each revolution of the main shaft. Light petroleum or gasoline is the fuel used. The motor runs at from 700 to 800 R.P.M., and indicates about 4½ H.P. Fixed to the driving shaft is a nest of epicyclic gearing,* which allows three different speeds to be transmitted and one reverse motion. There is also the usual differential motion. The carburator is of a simple and effective kind and requires but little attention to keep in order. All the mechanism is enclosed in a kind of box, which not only allows the gearing to run in oil but also keeps out dust, &c. This box is, by means of springs, attached to an axle, and, as before explained, the whole is easily fixed to any ordinary vehicle.

A company is being formed to place this motor on the market, the representative of M. Prétot being Mr. J. Melling, Dashwood House, New Broad Street, London, E.C.

ACETYLENE AND CARBIDE OF CALCIUM.

In an article on the cost of acetylene our contemporary, *l'Industrie Velocipédique*, expresses the opinion that under the most favourable conditions the price of carbide of calcium in France cannot yet fall below 300 francs per ton, or 1 franc per cubic metre of acetylene. Professor V. Lewes, R.N., is quoted as having said at the Royal Institution that 1,816 kilogrammes of a mixture of 100 parts of lime and 68 parts of coke will give 10·15 kilogrammes of carbide of calcium, and that the E.H.P. per hour, obtained by means of a waterfall, would cost about 25 francs per annum in England. It is, perhaps, incorrect to fix a yield per E.H.P. by reason of the loss due to breaking and packing of the carbide; thus, in an industrial undertaking it has been proved undeniably that the yield after leaving the electric furnace was 0·504 lb. per kilowatt hour, and that it had been reduced to 0·400 lb. per kilowatt hour when the carbide had been broken, sorted, and packed in air-tight packages. This loss of 20 per cent. is attributed to a bad quality carbide which formed a crust on the ingots and may be considered as a waste product.

Another point on which the professor insisted was the extreme importance of the purity of raw material. It is easy to find chalk fairly pure, and good coke with only traces of phosphorus and sulphur. But if the chalk and coke contain combinations of phosphorus, silica, and sulphur, the carbide and, naturally, acetylene will be impure, and it is not surprising if the latter would contain a very appreciable proportion of phosphoric hydrogen, silica, and sulphur. This is what will occur with impure carbide and a possible danger of spontaneous combustion, and would also produce an unhealthy and noxious combustion. Professor Lewes speaks of silicated hydrogen although the other authors do not admit of its existence in acetylene. We do not profess to say who is right, he or the others, on this point, but when the very small quantities of impurities, phosphoric or sulphuretted hydrogen, appear, it is easy to eliminate them by a suitably organised installation. We have also heard of azote as an impurity and its origin is attributed to coke; coal contains a fairly large proportion of azote, at least 1 per cent. or 10 kilogrammes per ton, and, on distilling, a large quantity remains in the coke. What becomes of it in the electric furnace?

According to a recent work by Messrs. Lunge and Cedercreutz there would be an advantage in making use of it for purifying commercial acetylene from hypochloride of soda or, better still, chloride of lime. Hypochloric acid salts have not, at an ordinary temperature, any action on acetylene gas; they oxidate phosphoric hydrogen easily and completely, which chemists have recognised, in a varying proportion of 93 to 248 cubic centimetres per kilogramme of carbide in the tests of carbide for different productions. With regard to the desiccation of liquid acetylene it can be realised by means of sulphuric acid, sufficiently concentrated, of a density 1·6 to 1·7; the ammonia would be retained as well as the moisture. For applying it as a means of lighting railway carriages a mixture with other gases is at present recommended. Acetylene which, condensed to two atmospheres, could explode at a dark red temperature becomes

---

* For the benefit of those of our readers who are interested in storage cells but who are perhaps not familiar with French scientific nomenclature we render this table of data as follows:—

Ampères, per lb.	1·5
Watts, per lb.	2·6
Ampère hours, per lb.	6·6
Units, per lb	10·012
Lbs., per kilowatt	420
Lbs., per unit	82

† No doubt the London Electrical Cab Company could say a good deal about this matter; the information they could supply would certainly be interesting and instructive.—Ed.

* *Vide* The Automotor for October, 1897, for a description of this gear.

more moderate when it is diluted; the explodable temperature increases from 100°C. to each 10 per cent. of other gas, so that very light and practically inexplosive mixtures can be made.

THE RIKER ELECTRIC MOTOR SYSTEM.

ON p. 146 of our current volume we gave a detailed description of the Riker Electric Motor Company's carriage. The accompanying illustration shows their new type of Electric Victoria, and, as introduced on this side by Messrs. Shippey Brothers. The motor is series wound, and has a slotted armature; its output is two kilowatts; it weighs but 142 lbs., and runs at 1,000 revs. per minute; the total weight of the vehicle being but 1,800 lbs., while it will run at 12 miles per hour on a good road for four hours. We understand that the Riker Company are shipping to their agents, Messrs. Shippey Brothers, a complete range of their latest type of vehicles, consisting of the Riker Electric Trap, the Riker Carriage, and the Riker Victoria, all of which will be shortly placed on the English market, and we understand an early opportunity will be given to those interested in automobilism to inspect these latest arrivals.

THE RIKER ELECTRIC VICTORIA.

will be seen, it is distinguished by great elegance in design, there being no unsightly mechanical projections which mar the appearance of so many vehicles. In designing this new type of Riker Victoria the great aim has been to ensure strength and lightness, and at the same time to permit of a good system of suspension. The frame consists of 1¼-inch steel tube, while the wheels are of cycle type with tangent spoke; the driving and rear wheels being respectively 36 and 32 inches in diameter, the wheel base being 6 feet. The battery consists of 40 cells of the new Woodward Multipolar battery, which are now used in the Riker vehicles, and are being

The Trend of Trade.—It is stated that a large quantity of American pig iron has been brought into the Clyde at 10*s*. per ton below the price for which English iron could be obtained in this country, and should it prove equal to specifications, it is said there will be a large importation.

THE Cafromobile is the name given to a small truck drawn by a couple of Caffirs or as we usually spell it—Kaffirs. This motor-vehicle is, we learn, in use in South-East Africa. Where is the Aborigines Protection Society?

ACCIDENTS TO MOTOR AND OTHER VEHICLES.

Defective Brake Gear.—At the Scarborough Town Hall on the 28th ult., the Coroner and a jury resumed their inquiry into the circumstances attending the death of John Vassalli, who was knocked down by a motor-vehicle belonging to the Bradford Motor-Car Company, in Newborough, on Friday, the 22nd ult., and who died at the Scarborough Hospital. William Pickles, engineer, Bradford, the driver of the car, deposed that on the morning of the day of the accident a new driving chain had been fixed on the car by Messrs. Walker and Hutton, of Scarborough; that he was proceeding down Newborough when the iron rod controlling the hand brake broke, and losing control of the car, it quickly gained an alarming impetus, becoming practically uncontrollable, and dashed into the old man just before he gained the footpath, with the result stated. Witness added that, in his opinion, the car was not sufficiently well designed in construction as regards the strength of the driving chain and brake rod and the disposition of the brakes to render it perfectly safe to pass over roads with an incline exceeding one to ten. The jury, after deliberating in private, said that death was due to accident, and they exonerated the driver, stating that he did his best under the circumstances. They found that the connecting rod was not of sufficient strength, that the driving chains were too light for a machine of this weight, and that the drum was also too small. The Coroner said he thought that on the evidence given them the motor-car was quite right, but he could not help thinking that in sending out these motor-cars or arrangements of this description too much care could not be exercised in testing them as to their strength in every particular.

Death of a French Nobleman.—At Périgueux, on the 2nd inst., during a speed competition organised by the Véloce Club, Perigourdin, over a distance of 143 kilometres on the National High Road, and at a spot called the Saut du Chevalier, a car weighing 850 kilogrammes, driven by the Marquess de Montagnac, came into collision with a very light vehicle, weighing only 180 kilogrammes, in charge of M. de Montariol, of Bordeaux. M. de Montariol succeeded in jumping off before his vehicle fell down the embankment, but his servant received severe injuries immediately after the shock, and, while his car was still in motion, the Marquess de Montagnac and his driver looked round to see what had happened. In so doing the stoker released his hold of the steering wheel, with the result that the car suddenly dropped down the embankment in its turn. Both of the occupants were dreadfully injured, and the Marquess de Montagnac expired a few hours afterwards, while his assistant is not expected to recover.

Danger of Horse-drawn Vans.—A young married woman named Gregory, of Stevenson Place, Long Lane, Bermondsey, while standing on the pathway late on the night of the 2nd inst., in Great Dover Street, Borough, was seen to stagger and fall beneath a passing pair-horse van. She was removed to Guy's Hospital, and found to have sustained severe internal injuries, to which she succumbed during the night.

Insufficient Brake Power.—A news agency says that a fatal motor-car accident is reported from Poitiers. A lawyer, named Hay, and his wife were returning from an excursion in an autocar, when the vehicle got out of control while descending a hill and overturned. Mrs. Hay fell under the carriage, and was killed on the spot. Mr. Hay escaped with severe injuries, both arms being broken and his head badly cut. Mrs. Hay was only 28 years of age.

The Stone Wall and the Motor-Vehicles.—A serious accident took place on the 28th ult., between East Kilbride and Bushy. Two motor-cars from Hamilton, going to Ayr Show, collided against a stone wall a little above Braehead. The vehicles were going at a good speed. The occupants were considerably injured. The local doctors were speedily on the spot and had the wounds dressed, some of them being rather serious. One of the vehicles was smashed to pieces.

A Motor-Vehicle on Fire.—In the Bow Road, on 26th ult., a motor-car—one in which apparently petroleum or oil was used for fuel—took fire in the middle of the thoroughfare, and the firemen were hastily summoned to extinguish the blaze. A few buckets of water sufficed, and the car retired for repairs.

The Post Office Mail Van.—The motor-van which conveys the night mails between Reading and Newbury met with a singular accident in the latter town on the 20th ult. The car was returning to Reading, between three and four o'clock, and while proceeding at a good pace along the main street the steering gear went wrong, and the vehicle dashed across the pavement, smashing a large plate-glass window in a stationer's shop and greatly damaging a quantity of stock. The car was detained at Newbury for the necessary repairs, which were quickly effected.

THE AUTOMOBILE CLUB OF GREAT BRITAIN.

At a meeting of this Club held on Wednesday evening, April 27th, a lantern display, which was voted a great success, of cinematograph views taken during the Easter Tour of the Club, showed the progress of the touring cars along the Hog's Back, and at Fareham, Hants. After the display a discussion took place on the arrangements and route for the Whitsuntide Tour. Mr. Roger Wallace, Q.C., presided, and amongst others present were Lord Kingsburgh, C.B., Sir J. R. Somers Vine, C.M.G., Major-General E. L. England, C.B., Messrs. A. W. Armstrong, G. F. Arney, W. Worby Beaumont, F. R. S. Bircham, A. Bird, E. H. G. Brewster, Frank Butler, R. W. Buttemer, Herbert C. Capel, F. T. Carter, T. Clarkson, C. Cordingley, R. E. Crompton, E. Estcourt, Staplee Firth, Cecil Grimshawe, C. Heyermans, W. M. Hodges, Ernest Instone, C. Johnson (Secretary), J. H. Knight, A. Ledger, E. Lefébure, C. Harrington Moore (Hon. Secretary), P. W. Northey, G. Foster Pedley, R. E. Phillips, J. D. Roots, Captain Sampson, J.P., Messrs. Lyons Sampson, E. R. Tebbitt, E. Townsend, &c.

The following Tour was ultimately decided upon:—

Friday, May 27th. London to Cambridge (62¾ miles).—Start from Club at 10.30 a.m., the route being *viâ* Horse Guards' Avenue, Whitehall, Cockspur Street, Waterloo Place, Regent Street, Portland Place, left side of Park Crescent, outer circle of Regent's Park, leave Park by gate opposite Baptist College, Avenue Road, Finchley Road, Child's Hill, Finchley, and by G. N. road to Barnet, Potter's Bar, Hatfield, Cole Green, Hertford; 2 p.m., luncheon at "Dimsdale Arms Hotel," Hertford; 3 p.m., leave Hertford for Cambridge, *viâ* Ware, Buntingford, Royston, and Foxton; 8 p.m., dinner at "Prince of Wales's Hotel," Cambridge.

Saturday, May 28th. Cambridge to Norwich (68½ miles).—9.30 a.m. leave Cambridge for Bury St. Edmunds, *viâ* Newmarket, Kentford, and Saxham; 1 p.m., lunch at Bury St. Edmunds; 2 p.m., leave Bury St. Edmunds for Norwich, *viâ* Ingham, Barnham, Thetford, Attleborough, and Wymondham; 8 p.m., dinner at "Royal Hotel," Norwich.

Whit Sunday, May 29th. Optional Circular Tour to the "Land of the Broads," viz., Cromer, North Walsham, Wroxham, and back to Norwich (62 miles).—10.30 a.m., leave Norwich for Cromer, *viâ* Coltishall, North Walsham, and Thorpe; 1.30 p.m., luncheon at Cromer; 2.30 p.m., leave Cromer for Norwich, *viâ* North Walsham, Stalham, Potter Heigham, and Wroxham Station; 8 p.m., dinner at Norwich.

Whit Monday, May 30th. (Alternative Routes.) Norwich to Ipswich (42¾ miles). A Route.—10.30 a.m., leave Norwich for Scole, *viâ* Long Stratton; 1 p.m., luncheon at Scole; 2 p.m., leave Scole for Ipswich, *viâ* Thwaite and Claydon; 7 p.m., dinner at "Great White Horse Hotel," Ipswich.

Norwich to Ipswich (54¾ miles). B Route.—9.30 a.m., leave Norwich for Saxmundham, *viâ* Brooke, Bungay, Halesworth, and Yoxford; 1 p.m., luncheon at "Bell Hotel," Saxmundham; 2 p.m., leave Saxmundham for Ipswich, *viâ* Wickham Market and Woodbridge; 8 p.m., dinner at Ipswich.

Tuesday, May 31st. Ipswich to Chelmsford (40 miles).—10 a.m., leave Ipswich for Colchester, *viâ* Washbrook and Stratford St. Mary; 1 p.m., luncheon at "Cups Hotel," Colchester; 2 p.m., leave Colchester for Chelmsford, *viâ* Witham; 7 p.m., dinner at "Saracen's Head Hotel," Chelmsford.

Wednesday, June 1st. Chelmsford to London (35¼ miles).—Mr. R. E. Crompton (a member) has kindly invited members to inspect his firm's works, at Chelmsford, on this morning. 1 p.m., luncheon at Chelmsford; 2 p.m., leave Chelmsford for the Club, *viâ* High Ongar, Epping, "Wake Arms," Waltham Cross, Enfield, Whetstone, up the Barnet Road and Finchley Road by the same route as at start. Supper at the Club.

The Liquid Fuel Engineering Company, of East Cowes, Isle of Wight, has kindly placed at the disposal of the Club, a "Lifu" steam van (with driver) as a tour luggage van. The Club steward will accompany this van to take charge of luggage.

Amongst those who have notified that they will probably take part in the Tour are:—Major-General England, C.B. (De Dion tricycle), Messrs. Boverton Redwood, F.R.S.E. (Daimler, 8 H.P.), Estcourt (Daimler wagonette), Wills (Benz Ideal), Frank Butler (Benz $2\frac{8}{10}$ H.P.), Heyermans (Mors), A. Ledger (Benz), Buttemer (Benz), Hewetson (Benz), Cecil Grimshawe (Daimler), Phillips (De Dion tricycle), Ernest Instone (The Daimler Motor Company's wagonette), Herbert Capel (Benz, or with Mr. Thomas Clarkson's steam carriage), E. Townsend (Bollée), Frederick R. Simms (Daimler carriage and De Dion tricycle), F. T. Carter (Bollée), Claude Grahame White (Daimler), Dr. C. E. Shelly (Arnold—from Hertford to Cambridge), A. D. Stopes (Arnold), Sir J. R. Somers Vine, C.M.G., Messrs. Ellis Parr, C. Harrington Moore, Louis d'Egville, Holland Tringham, &c. The Right Hon. Earl of Shrewsbury and Talbot (Phœnix Daimler carriage) will also take part in a portion of the tour.

Those who are not owners of motor-vehicles may book seats, through the Secretary, in the following motor-carriages, which have kindly been placed at the disposal of the Club:—Daimler Motor Company's carriage, 3 seats; Club (Daimler) wagonette, 5 seats; £3 3*s.* per seat for the whole Tour, or 12*s.* per seat per day.

The fullest details can be obtained upon application to the Secretary of the Club, 4, Whitehall Court, S.W.

Mr. R. E. Crompton (a member) has, in his capacity as engineer, kindly arranged that members should see over the Electric Lighting Stations at Westminster and Kensington, and subsequently visit his Laboratory at "Thriplands," Kensington Court, on Friday, 20th inst. The visit to the stations will be made on motor-vehicles, which will start from the Club at 8.30 p.m.

On Saturday last an evening run for dinner on motor-vehicles was arranged to Windsor and back, leaving the Club at 3 p.m., the start home being made at 8 p.m. We learn that the following carriages had been entered for this "run":—

- Club wagonette No. I (lent by the London Wagon and Van Company, Limited).
- Club wagonette No. II (lent by the Daimler Motor Company, Limited).
- Mr. Hugh Campbell's Daimler carriage.
- Mr. Frank Butler's Benz carriage.
- Mr. Harrington Moore's sociable.
- Mr. Northey's electric carriage.

Over 20 members booked seats for the "run" and for dinner.

The Committee of the Automobile Club of Great Britain have placed themselves in correspondence with the Customs authorities of the various European countries with a view to securing for members of the Club, and for owners of motor-vehicles generally, facilities for taking motor-vehicles into those countries free of duty. We have been supplied with copies of the replies which have been received to the present time, and as the matter is one of considerable interest to motor tourists we print them hereunder. It is evident that the Automobile Club of Great Britain is fully alive to the best interests of automobilism:—

Ministère des Finances,
Direction Générale des Douanes,
[*Translation.*] Paris, *le* 26 *Avril*, 1898.

Sir,—You did me the honour to write to me on the 20th inst., with a view to securing that members of your Club should be able to enter France with motor-vehicles intended for their personal use without being required to pay Customs duties.

The law does not permit the free importation of carriages of foreign manufacture, even if they be imported by private persons. But if it is not intended that the carriages should remain in France, the admission will be authorised under the ordinary regulations for the payment of duties subject to re-exportation during a year.

These duties will be refunded to the parties interested when the carriage is taken out of the country again—which, furthermore, may be effected through a Customs house other than that through which it was brought into the country—after a careful verification, and on showing the document given on the introduction of the carriage into the country.

Instructions to this effect have been given to the staff under my orders.

I am, &c.,
LE CONSEILLER D'ETAT,
Directeur Général.

To the Secretary,
Automobile Club of Great Britain.

Ministerie van Financiën, s' Gravenhage,
No. 88. 9 *May*, 1898.
[*Translation.*]

Sir,—With reference to your letter, I have the honour to inform you that motor-carriages and motor-cycles which are introduced into the Netherlands for a temporary stay by members of the Automobile Club of Great Britain are free of duties, or from giving any security for these duties, provided no fraudulent attempt be made, and on production of proof of their membership of the aforesaid Club.

I am, &c.,
for De Minister van Financiën,
(Signed) C. VAN DYCK,
de Secretaris-Generaal.

A SUCCESSFUL TRIP WITH A STEAM MOTOR-VEHICLE.

IN its issue of the 15th ult. the *Hawick News* gives an account of a most interesting run made by Mr. W. Philipson and Messrs. T. and W. Toward in one of the motor-vehicles that this firm, or rather the two firms of Messrs. Atkinson and Philipson and Messrs T. and W. Toward have jointly constructed. We may mention that here we have an excellent illustration of the success that attends an intelligent co-operation of the carriage builder with the engineer. Messrs. Philipson and Atkinson are, as no doubt our readers know, a leading firm in the North of England in carriage building, while Messrs. Toward have established a reputation as traction engineers. By working together and making the experience and knowledge of the one supplement that of the other, they have produced a type of steam motor-vehicle which has given great satisfaction, and several orders are now on hand. Says our contempory:—

"A motor-car being still somewhat of a novelty, the appearance of one in High Street on Saturday evening, the 9th ult., attracted much attention, crowds following it along the streets towards the yard of Mr. Robson, wood merchant, where it was put up for the time being. The car was accompanied by Mr. William Philipson, of the firm of Atkinson and Philipson, carriage and harness manufacturers, Newcastle-on-Tyne, by whom the car was built, and along with him were Messrs. Thomas and William Toward, of the firm of Messrs. Toward, engineers, the makers of the engines by which the car is propelled. The trio were on an experimental trip, having started from Newcastle on Thursday evening, and proceeded to Hexham the same night. On Friday they came on to Carlisle, a distance of some 40 miles, viâ Haltwhistle and Greenbank. At the latter the rubber tyre of one of the wheels slipped off, and they had to proceed without it. On Saturday about mid-day they left the 'merrie city' for Hawick, about 45 miles, reaching their destination shortly after 8 o'clock. At Langholm a halt was made for a couple of hours. The car is not constructed for swift running, but it can easily do 20 miles an hour, though the speed is restricted to 12 by Act of Parliament. Mr. Philipson is of opinion that motor-cars are best adapted for heavy traffic, such as that carried on by omnibuses, cars, lorries, and carts. The firm are busy making a motor-car wagon to carry 3 tons of coal. It is found that steam is the most suitable motive power for such cars; gas or oil may be used for light cars. A car, including the engines, costs from £300 to £500; but the expense of running is very slight, $3\frac{1}{2}d.$ worth of coke being sufficient fuel for 20 miles. Water requires to be taken in every 10 miles or so. Messrs. Atkinson and Philipson, it may be mentioned, do an extensive trade in the construction of ordinary carriages, and are the holders of 25 gold and silver medals for the best designs in carriage building. The motor-car in question is a wagonette with seats for two in front and four behind. The body is mounted by means of three elliptic springs on a steel double-perch under-carriage of original and protected design. This under-carriage frame carries the boiler and engines, and is, in turn, supported on the hind axles by spiral springs, and on the front axle by side springs, which effectively relieve all vibration. The boiler is of the fire tubular type. Steam is generated by a coke fire, the fuel being fed by an ingenious device from the top by one of those sitting in the carriage. The motor itself consists of a pair of light, high-pressure, horizontal reversing engines, capable of propelling the carriage with six passengers up an incline of 1 in 9, at a working pressure of 175 lbs. per square inch. The engines have long connecting rods and ample wearing surfaces, and are geared direct from the crank-shaft to the hind axle and driving wheels with pitched chain and sprocket wheels. The driving axle has a very compact differential gear. The steering gear is worked by a vertical spindle and lever and pivoted axles, and is easily controlled, while the reversing gear, foot and screw brakes are very convenient for the driver. The wheels have solid rubber tyres, which are more suitable for motor-cars than pneumatics. No 4 looks well and workmanlike on the road, and we may safely conclude that it is a success, as the builders are now engaged on No. 7.

"The car, which weighs 18 cwt., left Hawick on Monday morning shortly after 9 o'clock on the return journey to Newcastle, viâ the Carter Fell. Its movements were again watched with great interest by large crowds as it passed along the streets, turning the corners very cleverly, and moving very smoothly and with very little noise."

THE Winton Motor Carriage Company have issued a challenge to any American or European manufacturer of motor-carriages to race them from Chicago to New York, or over any other route of not less than 1,000 miles, in the United States. The terms require that competitors shall use regular single-seated commercial machines, carrying a driver and one passenger. We have not seen this challenge but should like to.

THE ELIESON ELECTRIC CAB AND VAN.

WE have in previous issues described at some length the progress that the Elieson Lamina Accumulator Company, of Camden Town, N.W., has made in perfecting its system of electric traction. It will be remembered that one of the most important features of this system is the absence of any differential gearing; this is effected by using a specially formed chain,* which, while gripping the driving wheels sufficiently to ensure rotation of the latter, is yet, by its peculiar construction, enabled to slip wheuever one or the other of the two wheels is forcibly retarded in its speed, as when it forms the inner wheel in rounding a curve. This method is not only very simple, but effective, as we can testify from personal observation. This gearing is practically noiseless. In other respects, too, considerable ingenuity is displayed in overcoming various practical difficulties, and at length this firm has produced an electric cab, which we illustrate herewith, and which, whether as regards its elegance of design, or its mechanical details, leave little to be desired. This vehicle, as will be seen, is a marked advance upon the ordinary electric cab such as we are accustomed to see in the London streets. The motor is made so as to allow the Field magnet coils to be placed either in series or in parallel. The current is derived from a battery of 40 Lamina cells, and when discharging at 20 ampères the capacity is 160 ampères hours. All the cells are grouped in series, hence they do not suffer from unequal rates of discharge. The total weight of the battery is about 10 cwt., and the weight of the vehicle in working order about 1 ton.

We also give an illustration (Fig. 2) of their latest design in electric delivery vans. It will be seen that while preserving the same general features the motor in this case is placed in front of the

FIG. 1.—THE ELIESON ELECTRIC CAB.

* *Vide* THE AUTOMOTOR, May, 1897.

driving wheels. The weight of the battery is about 12 cwt., and the total weight 22 cwt. Objection might be taken to the prolongation of the tubes and to the manner in which they are curved up. While in the event of a collision this prow would prevent damage to the van in question, it might possibly inflict damage to the colliding body. The arrangement of the cells and switching gear is the same in both vehicles.

We understand that several orders for these cabs and vans have been placed; some prolonged tests having shown that they fulfil every requirement for street traffic.

AUTOMOBILISM AND POLICEMANISM.

MESSRS. W. A. MARTIN AND Co., who were recently summoned for obstruction with a motor-vehicle, writes to a contemporary as follows:—"It may be of interest to the owners of motor-cars to learn our experience on the road, with regard to the police regulation. We have been making a number of experimental runs to test the working appliances, and to give the drivers an opportunity of acquiring experience in steering. On returning through Clapham recently, we had to stop a few minutes in consequence of a screw breaking belonging to the steering gear, and as we were ascending a hill the steam lifted the safety valve. We were instantly surrounded with two or three policemen, ordering us to move on. This we could not do for a few minutes. Our name and address were taken, and in a few days after we received a summons to the South-Western Police Court for allowing a locomotive to be run without sufficient control. Upon the case coming on for hearing, it was found that the policeman had made a mistake, as the car was stopped and under perfect control. The case was adjourned for a fortnight, and another summons issued under another head, for permitting a car to be used that the fittings being in such a condition as to be likely to cause danger to persons on the highway. As no one on the part of the police had examined the car, or knew anything about it, the magistrate dismissed the summons. If cars are to be used on the common roads, the police should have instructions as to the regulations to be observed. Even the court did not possess a copy until the second summons was heard. This, it appears, was the first summons under the Act, therefore some excuse for blundering; but why a motor should not be permitted to stop a few minutes on the road, to correct any trifling defect that may happen, as well as ordinary carriages and vans, is difficult to understand."

Action Against a Motor-Vehicle Company.—On May 10th, at Coventry County Court, Hannah Terry, carrier, Corley Moor, near Fillongley, sued the Daimler Motor Company (Limited) for £19 6*s.* 6*d.*, damages sustained in a collision with a motor-car on January 31st. On the date named, Mr. Seward, in the employ of the Daimler Motor Company, was bringing back some things shown at Bingley Hall Exhibition, and when near Coventry a collision occurred between the motor-car and the carrier's cart. Plaintiff and a Mrs. Fennimore were both upset and injured. After hearing the evidence, the jury found that the driver of the motor-car was not guilty of negligence, and a verdict was entered for the defendants, as also, by consent, in a second action brought by Mrs. Fennimore.

ELECTRIC TRACTION AND ELECTRIC FRICTION IN LIVERPOOL.

THE Tramways Construction Committee decided by seven votes to three to order for use on the experimental electric tramway between St. George's Church and the Dingle, 14 German electric cars—seven of the Altona type and seven of the Ring-Bahn type—with trailers to each. The cars, with their trailers, will accommodate 50 persons each. The Committee resolved to leave Sir Arthur Forwood to order 14 other cars from America, provided the specification of the electrical work was altered so as to fulfil the requirements of Dr. Hopkinson, consulting electrical engineer to the Corporation. About four months must elapse before the cars are ready for use. The Committee are desirous of seeing both the German and American cars at work, with the object of adopting a car of their own pattern which they hope to have made in Liverpool. The City Council refused to agree to the recommendation of the Generating Stations Committee (of which Sir Arthur Forwood is the chairman) to accept tenders for the supply of electrical generating engines of a certain type, whereupon Sir Arthur intimated that he had striven during the last two years to provide the city with a worthy tramway system, but his committee had not received the support and sympathy of the Council. He, therefore, not only would resign from the Committee, but that would be the last occasion upon which he would be present in that chamber. This is not the first time Sir Arthur Forwood has resigned from the Tramway Committee.

FIG. 2.—THE ELIESON ELECTRIC VAN

THE Newton Rubber Works Company are manufacturing a 10-inch pneumatic tyre for heavy motor-vehicles. Four of these gigantic tyres are capable of sustaining a weight, so says the *Horseless Age*, of 8,000 lbs. They claim to be the only manufacturers in the United States able to turn out such tyres.

Z 4

DOINGS OF PUBLIC COMPANIES.

Dick's Asbestos Company, Canning Town, inform us that they have taken offices at Nos. 51 and 52, Fenchurch Street, E.C.

The Right Hon. Lord Rathmore has joined the board of directors of the British Electric Tramway Company (Limited).

The Motor and Cycle Company of Ireland (Limited).—Mr. Robert Gardner, the liquidator of this Company, last month repaid to the ordinary shareholders a final sum of 1*s.* per share. By this payment the ordinary shareholders are refunded all monies paid by them, and as the preference shareholders were repaid in full in September last, the entire amount of the subscribed capital has now been returned. Would that the same could be recorded of all other companies.

New Issue.

The Scottish Motor Hiring Company (Limited).—This Company has been formed for the purpose of acquiring, as a going concern, the business and assets of the Scottish Motor Omnibus and Car Company (Limited), Hamilton, and of carrying on, developing, and extending the same. The capital is £25,000 in £1 shares, of which 15,000 are now issued at par. In addition to continuing and extending regular services of cars on fixed routes, the directors propose to arrange summer motor-car tours in Scotland, England, and Ireland, summer holiday excursions, popular half-day trips, and to give facilities for hiring by the hour, day, week, or month. To meet this extension of business, arrangements have been made for the early delivery of 30 motor-cars, equally serviceable for passenger and goods traffic. The balance sheet for the first quarter, ending January 25th last, under the old Company showed a gross profit on the three months' working at the rate of 35 per cent. per annum on the subscribed capital, and the shareholders have been paid an interim dividend at the rate of 20 per cent. per annum.

Austen's Patent Wheel-Making Machine (Limited).

The first ordinary general meeting of the shareholders of this Company was held on April 29th, at the registered offices of the Company, 10, Drapers' Gardens, E.C. Mr. Charles Lloyd Roberts (the chairman of the Company) presided.

The Secretary (Mr. Charles J. Coombes) having read the notice convening the meeting,

The Chairman during his speech said: Most of you are well acquainted with the machine to the protection of which the patents apply. Briefly it may be described as a small power-driven tool for screwing up the nipples on the spokes of tension wheels, the principle being that the nipple is screwed on to the spoke until the latter comes through the nipple, when it presses back a catch, which throws the machine out of gear and stops it, then another spoke is inserted and the machine started again, and so on until every spoke in the wheel is tightened to the tension required. In action it is so simple that a boy without any special training can true up a wheel inside of two minutes, whereas by the old hand-method a man, highly paid by time—a skilled wheelmaker—seldom made more than, say, 10 wheels for his day's work; the average number was about six, I believe. We are now in a position to supply machines to manufacturers to be worked on a royalty of a fixed sum to be paid on each wheel manufactured, the machines meanwhile remaining our property. Messrs. Humber and Co. have, among others, already completed arrangements to use our machines, and from this one firm alone we should derive a very handsome income, while we hope and confidently expect that in a few months' time every large cycle manufactory will be using our machines on similar terms. In addition to thus letting out the tools on royalty we have a large and convenient workshop, fitted with complete wheel-making plant and enamelling ovens, in Whitechapel, where we make up wheels either from the materials our customers supply us with, or sell the complete wheels. This branch of our trade is, I am glad to tell you, already meeting with most gratifying support, and evidently supplies a need long felt by those smaller cycle makers who hitherto have experienced much difficulty in obtaining wheels made and guaranteed true at anything like short notice, or at relatively small expense. At seven days' notice, I may say, we are now prepared to guarantee delivery of wheels, accurately trued, in any number asked for. So much for cycle wheels. But this is not our only resource for supplies of work or the profits incidental on same. We shall be prepared to supply tension wheels of the highest class of excellence for use on carts, carriages, or motor-cars and vans, and can do so at prices considerably lower than those now ruling for wooden wheels of ordinary quality. We would also lease machines for making this class of wheels in a similar manner to the ones for cycles.

A Shareholder. Are Humber's going to make all their wheels with our machines?

The Chairman. Certainly, except wheels made with direct spokes. They have given us permission to use their name publicly, and they will also be very glad to show any of our machines at work at their place in Coventry.

Mr. Myall. How many machines have they?

The Chairman. Two, and one machine is capable of making 100 wheels per day.

Mr. Myall. Have you any idea of the average output of bicycles per annum?

The Chairman. I should think quite 1,000,000 bicycles are made in a year—that is 2,000,000 wheels. In addition to that there are as many perambulator wheels as bicycle wheels manufactured in the course of 12 months. Then we have other machines for making carriage, motor, and other wheels, as mentioned in my speech.

A vote of thanks to the chairman and directors terminated the proceedings.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

Electric Horse Promotion Syndicate (Limited).—Registered by Chapronière and Co., 11, Charing Cross, W.C.; capital £5,000, in £1 shares. Object, to adopt an agreement made by this Company with J. Lambert, and to acquire and turn to account certain patents.

Electric Light and Power Company (Limited).—Registered by Markby, Stewart, and Co., 57, Coleman Street, E.C.; capital £6,000, in £1 shares (5,003 deferred). To carry on the business of an electric light company and supplier of motive power, and the business of electricians, electrical, mechanical, and general engineers, &c.

Electric Railway and Tramway Carriage Works (Limited).—Registered by Waterlow and Sons (Limited), London Wall; capital £150,000, in £5 shares. Object, to carry on at Preston, Lancashire, and elsewhere, the business of manufacturers of and dealers in tramway-cars for horse, electric, and cable roads, and vehicles for light railways, and any other kinds of cars and rolling stock, whether worked by electricity, steam, gas, oil, horse, or any other mechanical power. The first directors are:—G. Flett, G. F. Fry, J. Kerr, R. H. Prestwich, and G. Richardson. Registered offices, 13, Spring Gardens, Manchester.

Felsche's Patent Tube-Joint Syndicate (Limited).—Registered by Ashurst and Co., 17, Throgmorton Avenue, E.C.; capital £700, in £1 shares. Object, to adopt an agreement with Felsche, Roderwald, and Co., to acquire certain patents, and to manufacture, sell, and deal in bicycles, vehicles, and carriages of all kinds.

Hillsdon and Stones (Limited).—Registered by R. Brooks, 24, Lawrence Lane, E.C.; capital £6,000, in £1 shares. Object, to carry on the business of cycle manufacturers, motor and carriage builders, engineers, &c. Registered office, Alexandra Works, Alexandra Gardens, Folkestone.

Lancaster Light Railways (Limited).—Registered by F. J. Leslie and Co., 15, Union Court, Castle Street, Liverpool; capital £50,000 in £1 shares. Object, to construct and maintain rail and tram roads in Lancashire, to be worked by means of horse, steam, electric, or other power.

Mansfield Motor-Car Company (Limited).—Registered by Jordan and Sons (Limited), 120, Chancery Lane, W.C.; capital £5,000, in £10 shares. Object, to carry on the business of automotor manufacturers, electrical, gas, and mechanical engineers, &c. The first directors are:—W. J. Chadburn, G. A. Fish, F. Hamever, F. A. Robinson, R. F. Vallance, and J. J. Ward. Registered office, 24, Leeming Street, Mansfield.

Scottish Motor Hiring Company (Limited) (Hamilton).—Capital £25,000, in £1 shares. Object, to carry on the business of motor-carriage proprietors and carriers (Scotch Company).

Thomas and William Coldwell Syndicate (Limited).—Registered by Waterlow Brothers and Laytou (Limited), Birchin Lane, E.C.; capital £3,000, in £10 shares. Object, to carry on business as manufacturers of and dealers in outer covers or tyres for wheels of cycles, carriages, and other road vehicles.

Yorkshire County Cycle Company (Limited).—Registered by Lupton and Fawcett, Leeds; capital £100,000, in £1 shares. Object, to manufacture, sell, and deal in cycles, motor or horseless vehicles, carriages, cycle components, &c. N. R. Hepworth is appointed sole governing director.

Strength of Cycle Frames.—A test of the strength of a safety bicycle frame is recorded in a recent issue of the *Iron Age*. The frame of the bicycle was made up of the following sizes of tubing:—

	Diameter.	Thickness.
Head tnbe	1¾ inches.	No. 23 W. G.
Upper resch tnbe ..	1¼ „	No. 22 „
Lower „ ..	1¼ „	No. 22 „
Seat-post tnbe	1¼ „	No. 22 „
Upper rear fork tube ..	¾ inch.	No. 22 „
Lower „ „ ..	¾ „	No. 18 „

The bicyclo was supported at the wheel centres, and loaded over the seat-post. The first permanent set was noted with a load of 1,800 lbs., with which the total deflection was $\frac{1}{10}$ inch, and the permanent set $\frac{1}{30}$ inch. When the load reached 4,200 lbs., the total deflection was 0·28 inch, and the permanent set ·014-inch. With a load of 4,362 lbs. failure occurred, the front fork bending outwards, bnt without breaking.

To Inventors.—Just now inventors are particularly busy with motor-vehicles; but we who have to wade through multitudinous specifications do not often come across very much worth reproducing or which promises to yield practical results. When we say that as regards the water-tube boiler there have been no less than some 2,200 patents taken out it will be seen, taking into consideration the very few really successful water-tube boilers, how useless and impracticable must be many of these inventions. In this connection it is just as well to recall some words of Rankine written a good many years ago. Said this distinguished engineer:—"An evil which arises from the separation of theoretical and practical knowledge is the fact that a large number of persons, possessed of an inventive turn of mind and of considerable skill in the manual operations of practical mechanics, are destitute of that knowledge of scientific principles which is requisite to prevent their being misled by their own ingenuity. Such men, too, often spend their money, waste their lives, and, it may be, lose their reason, in the vain pursuit of visionary inventions, of which a moderate amount of theoretical knowledge would be sufficient to demonstrate the fallacy, and for want of such knowledge many a man, who might have been a useful member of society, becomes a being than whom it would be hard to find anything more miserable."

President	Sir David Salomons, Bart.
Secretary	Andrew W. Barr, Esq.
President of the Liverpool Centre	The Earl of Derby, K.G., G.C.B.
Hon. Local Secretary	E. Shrapnell Smith, Esq.
Semi-Official Journal of the Association	The Automotor and Horseless Vehicle Journal.

SELF-PROPELLED TRAFFIC ASSOCIATION

(INCORPORATED).

LIVERPOOL CENTRE.

Trials of Motor Vehicles for Heavy Traffic.

May 24th to 27th, 1898.

Mr. E. Shrapnell Smith, the Hon. Sec., notifies that a dinner will be held at 7 o'clock, at the Adelphi Hotel, Liverpool (Brownlow Hill Entrance), on Thursday Evening, May 26th, 1898.

The President of the Liverpool Centre, the Right Hon. the Earl of Derby, K.G., is expected to preside, and the President of the Association, Sir David Salomons, Bart., will also be present.

Tickets, including wines, will be one guinea each, and may be obtained from the Hon. Sec. upon receipt of remittance.

No tickets will be issued after Saturday, the 21st May, 1898.

Special cards of invitation have been prepared for those members who may wish to introduce their friends, for which an early application should be addressed to the Hon. Sec.

Depôt—South-west corner of Prince's Dock, close to the Riverside Railway Station.

A limited number of light carriages have been secured, for the purpose of enabling members, their friends, and others interested, to follow the competing vehicles. Seats may be booked at 10s. each per day. Early application is recommended. Tickets (transferable) available for the four days, £2 each.

These carriages will be in charge of experienced motor-men, and will provide a means of observing the behaviour of all the wagons on any one day.

The War Office, the Post Office, the Automobile Clubs of France and Belgium, and other important bodies, have appointed official delegates to the trials.

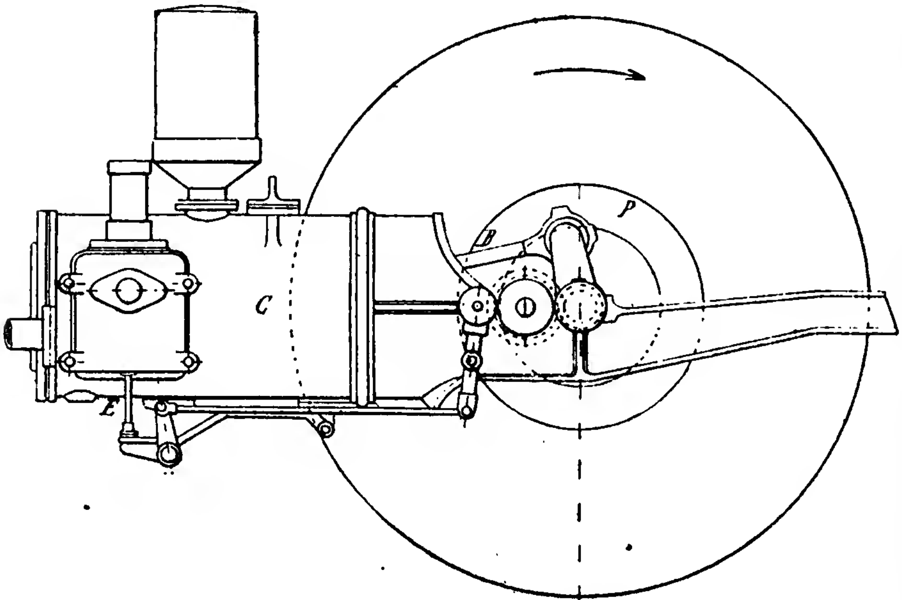
The Council will be pleased to consider any special names submitted to them by members as being eligible for official invitations or notifications.

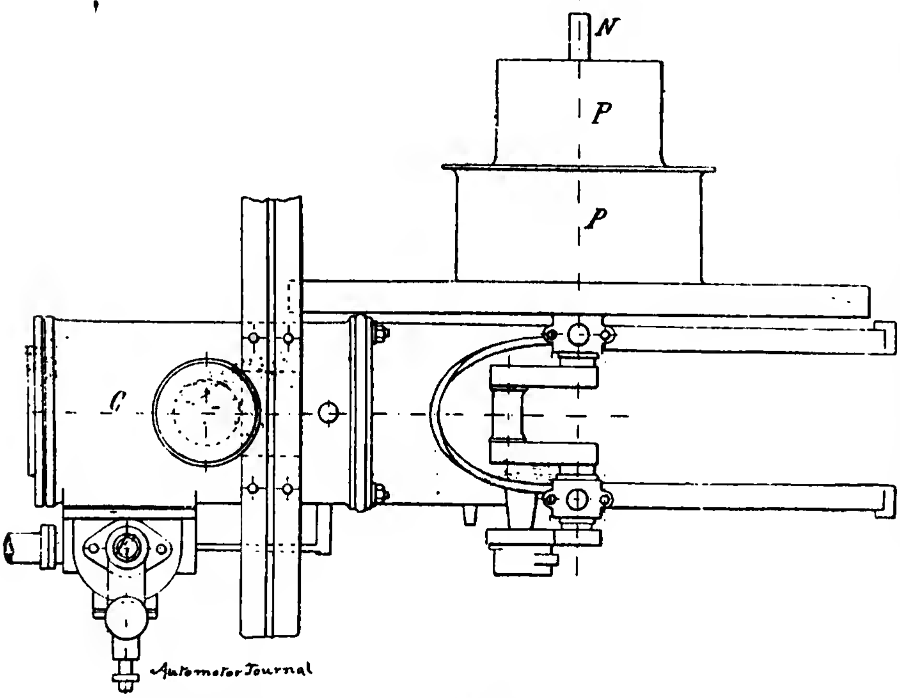
Route maps have been prepared of the whole of the routes which the cars will have to follow. These maps give the profile view throughout the journey, but the rules governing these trials require that they shall not be published till the runs begin. Mr. Shrapnell Smith has personally been round the routes and arranged depôts for re-victualling, &c.

THE BENZ MOTOR.

Among the many forms of light petroleum or spirit motors used for vehicles, the Benz has obtained a deservedly high reputation, especially in Germany and Italy, the majority of the motor-vehicles in these countries using this motor, while in France the firm

Benz Motor.—Fig. 1.





Benz Motor.—Fig. 2.

known as La Maison Parisienne de Voitures Automobile also use it in their well-known vehicles. Mr. Chas. Benz made his first motor in 1878, and it was of ¾ H.P., with electric ignition. It was applied to a tricycle, and a speed of 7 miles per hour was obtained. About 10 years ago the Benz motors and vehicles were introduced inio France by M. Roger. In 1889, in the Paris Universal Exposition, one of these vehicles was shown, and it was the only motor-vehicle there. In 1896 the present arrangements with La Maison Parisienne were made. The Benz motor, as now perfected, is made in three types. The first and oldest is a single horizontal cylinder motor, working on the Beau de Rochas cycle, with electric ignition (*see* Figs. 1 and 2).

The next type is a motor having twin cylinders arranged as in Figs. 3 and 4, while the remaining type is a motor having two opposite cylinders (*see* Figs. 5 and 6). The general arrangements are clearly shown, the valves being actuated by means of cams and levers driven by a secondary shaft, as shown in Fig. 1. The electric ignition consists of an induction coil energised by a couple of small storage ... ›nt is led to the igniter, ... f a porcelain tube and ... The supply of oil is ... ›at and needle valve. In ... the motor is simple and ... ısily learns to run it. Of the three types mentioned the single cylinder motor is applied to small vehicles, as shown in the illustrations in The Automotor for November, 1896, and June, 1897.

In the larger vehicles, such as the delivery vans or omnibuses, two-cylinder motors are employed. In the char-a-banc, No. 15 of Les Poids Lourds Competition, a 9 H.P. motor was used. Of the three types, that illustrated in Figs. 5 and 6 is to be preferred, as a much better balance can be obtained; on the other hand much more room is required. The two-cylinder arrangement shown in Fig. 3 is generally preferred. As will be seen, the cranks are placed at 180°; thus while one cylinder is making its firing stroke the other is exhausting, and while the former is compressing the latter is firing; there is thus an impulse at every revolution. Usually the cranks in many two-cylinder motors lie in the same radial plane, or $\theta = 0°$. In this case while one cylinder is making its firing stroke, the other is pumping or inhausting, and while the former is exhausting the latter is compressing. Some doubt exists with many engineers as to which is the better arrangement, but we prefer the Benz, as a little consideration will show that for the Beau de Rochas cycle this arrangement is better, as producing a more regular turning moment. In practice these motors run, however, extremely well, and seem to be free from many of the troubles which afflict most light oil motors. Of course, even with the Benz there is a quantity of gearing necessary in order to effect speed regulation, reversing, turning, &c., but as far as possible simplicity has been aimed at.

Belts are used to transmit the motion, and we understand that, if properly looked after, these give no trouble; they certainly avoid much gearing and are quieter—a point of considerable value. The Benz is favourite not only with automobilists on the Continent but also on this side, no less than four being at the recent meet of the Automobile Club. A good feature of them is that the motors are horizontal, and hence all the space of the vehicle can be utilised for passengers or goods.

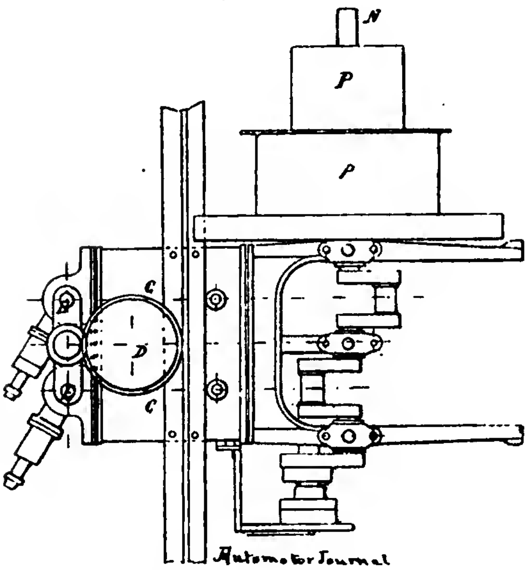
There will be an exhibition of cycles, motor-vehicles, &c., at the Agricultural Hall, London, from November 18th to 26th.

THE BICKFORD BURNERS FOR AUTOMOBILISM.

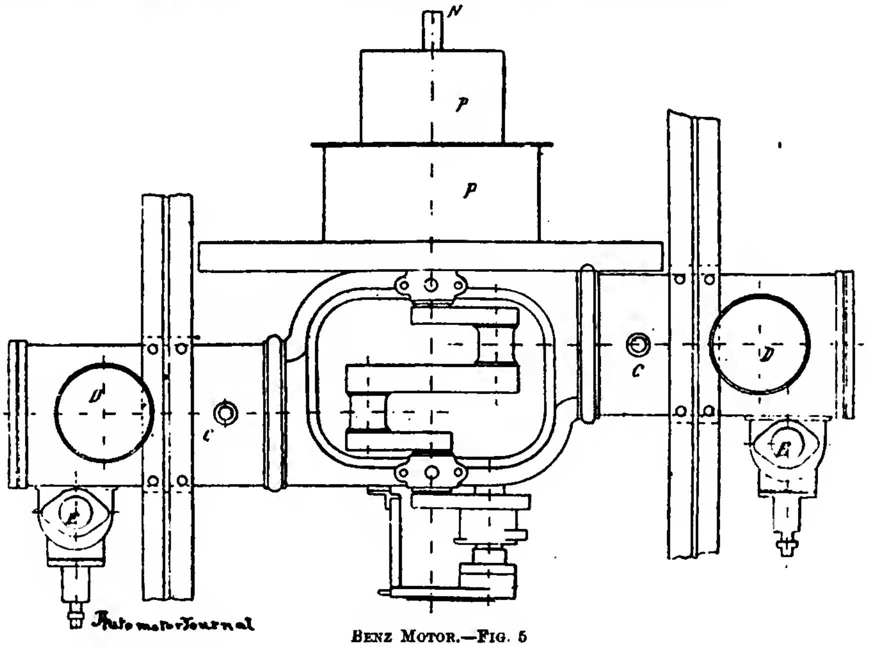
Messrs. Bickford and Co., of Camborne, in the course of a letter to us, write:—We are introducing improvements in the firing of small steem-boilers which, we believe, ere wortby of the careful attention of all owners of steam launches, steem road-cars, &c.

Tbe adventeges of our system of liquid-fuel firing are:—Always plenty of steam; adaptability to existing boilers; no smoke, coal, dust, or dirt; steam up in half the time; fuel obtainable everywhere; utmost simplicity; no trouble. The common objections to liquid fuel are that it is noisy and that the liquid-fuel burner cannot be started till steam is up, end, consequently, that liquid fuel cannot be used for raising steam initially. In our burners these difficulties are overcome; tbe boiler makes little if any more noise than a coel fire of equal power, and is worked without either steam or air blast. Where a boiler is fitted with one of our burners the process of raising steam is unique in its simplicity. A match is applied to a wad of asbestos soaked in oil which is placed in position under the burner, then, after waiting seven minutes and opening two cocks, the furnace is working et full power. Steam is consequently raised in about half the time necessary with coal. Tbe intensity of the fire is controlled with tbe utmost nicety by a cock placed in any convenient position; hence there is no stoking with its dust and dirt, end, the fire being just as powerful as desired, there is no lack of steam.

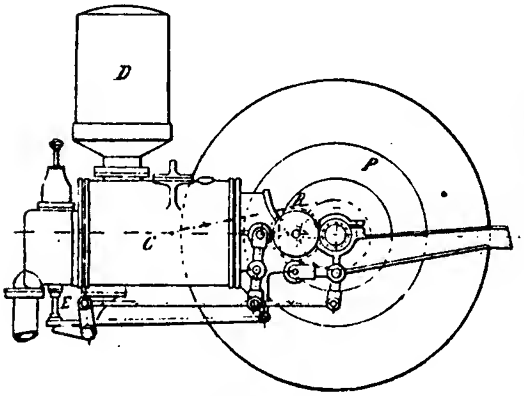
If the engines have been stopping for some time there is no waiting to get fires up when it is desired to start. During short stops the burner is kept hot and ready for immediate work, and steam is kept up in the boiler by a small burner which consumes about one pint of oil per hour. Our burners use common petroleum lamp-oil procurable in any village. They can be fitted to almost any boiler in a few hours without alteration to boiler or furnace. They require no spirit whatever. A steam launch or motor-car fitted with one of these burners can travel twice as far with the same bunker capacity as with coal. Prices, from 25s. for ordinary burners; from 52s. 6d. for bunsens.



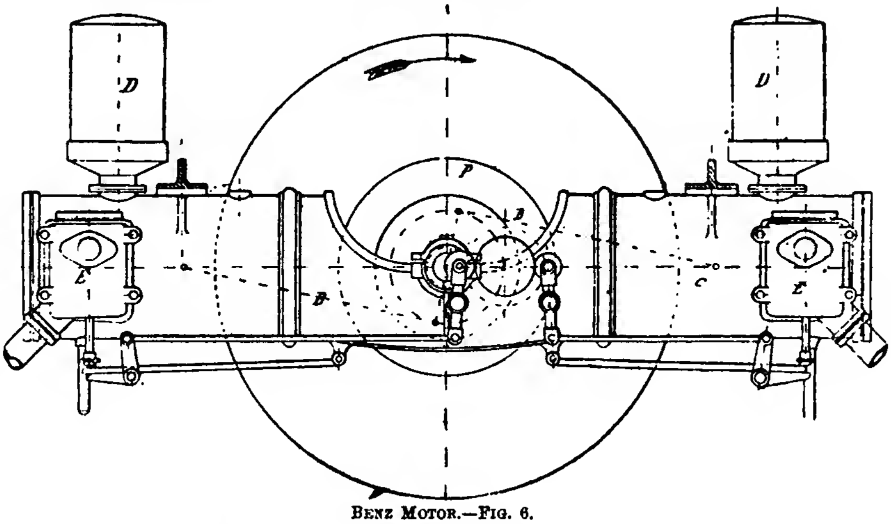
Benz Motor.—Fig. 3.



Benz Motor.—Fig. 5



Benz Motor.—Fig. 4.



Benz Motor.—Fig. 6.

We regret to record the death of M. Hertu, the well-known French automobilist. He was the founder of the firm of MM. Hertu, Henlin, and Deligeon. He was a Chevelier of the Legion of Honour. He was living in retirement for some yeers before his death.

NOTES OF THE MONTH.

IT is worthy of note that the recent Easter trip of the Automobile Club was accomplished without any accident whatever.

AN extension of patent has been granted to the Hon. C. A. Parsons for his now well-known turbine which has been fully described in THE AUTOMOTOR.

THE 22nd annual Stanley Show of cycles, cycle accessories, cycle-making machinery, and motor-carriages will be held at the Royal Agricultural Hall, London, N., on November 18th to 26th, both days inclusive.

ACCORDING to the figures given by the Chancellor of the Exchequer in the recent Budget, the cost of public defence is £175 per 1,000 head of population; in France it is £399 per 1,000; in Germany, £560; and in Russia, £298.

IT is said that Meyer, the celebrated cyclist, has withdrawn from the famous Paris-Bordeaux race. He contends that the adoption of the automobile as a pace-making machine is unfair and unjust.

ACCORDING to Mr. Douglas Young, who doubtless takes his figures from official statistics, 107,421 persons cross London Bridge every day, and 14,367 vehicles; while for Blackfriars Bridge the figures are 69,898 and 8,287 respectively.

MR. SAUNDERSON, of the Kempston Engineering Works, has produced a new motor-vehicle which he claims to be in advance of any other. The car is intended for exhibition at the Royal Show in June next, and a trial to test its powers and capabilities was recently made.

AN official estimate states that of the total internal goods traffic of France, 69 per cent. passes over the railways, 22 per cent. over the navigable ways, and 9 per cent. over the main roads. The railways have an aggregate length of 21,300 miles; the various navigations, 7,600 miles; and the main roads, 24,600 miles.

THE Blackpool Motor-Car Company are inaugurating a system of letting out motor-vehicles to hotels, and Mr. W. H. Blackhurst, of the Crown Hotel, Fleetwood, has lately obtained a license from the local magistrates to use it in connection with trips from his house. No doubt visitors will appreciate this new departure.

MESSRS. PHILLIPS, ORMONDE, AND CO., the well-known patent agents of Melbourne, and local agents for THE AUTOMOTOR, recently brought to the notice of the Postmaster-General for Victoria the advantages of the motor-vehicle for postal purposes, as exemplified by the experience of the British and French postal authorities. The Postmaster of Victoria, however, does not think that the time has yet arrived for their use in that colony.

A STRONG and lasting cement for rubber, either on metal or wood, is said to be made as follows:—Put one part of shellac, broken into small pieces, into 10 parts of ammonia water—strongest—and set aside for three or four weeks, or until the mass becomes entirely fluid. In use the liquid is applied to the india-rubber surface, and the latter is applied to the metal or wood, and firmly wired or corded thereto. On the evaporation of the ammonia a most complete joint is formed between the two surfaces.

WE regret to record the death of Colonel Sir Vivian D. Majendie, K.C.B., the distinguished expert on explosives and petroleum, which occurred on the 24th ult. Quite recently he gave valuable evidence before the Select Committee of the House of Commons on the petroleum question, and declared against raising the flash point of ordinary burning oil. He was an authority on this and kindred matters of the highest order, and was constantly consulted by our own and foreign Governments on questions relating to the higher explosives.

THE London Motor Van and Wagon Company recently sent down to Clacton-on-Sea one of their pleasure motor-cars, which they propose to run there during the season, and at the invitation of the manager, several residents, including a few members of the Council, had "free rides" on the machine to test its qualities. The Company have decided to commence running at Whitsuntide, and stated that as their only object is to advertise the machines they do not wish to compete against the jobmasters in the place, and their fares will be higher than those charged by the brakes.

A MOTOR-CAR Company has been formed at Falkirk, and at a recent meeting of the magistrates of the burgh it was agreed to grant a licence to them to run three cars, to hold eight persons each, and to ply between Falkirk and Stenhousemuir. The cars, which are already in use in the town, have been largely patronised, and are creating a considerable amount of interest. The distance between Falkirk and Stenhousemuir is three miles, and the journey is performed in twenty minutes. Other cars are shortly to be run between Falkirk, Camelon, Laurieston, and Bonnybridge.

AMONG the subjects for which the Academie des Sciences of Paris lately invited papers and contributions, for which it offered various prizes, was this:—"Give the theory of the motions, and a special discussion of the conditions of stability of apparatus of the velocipede class, bicycles, &c., both for rectilinear and curvilinear paths, either on a horizontal or inclined plane." Ten memoirs were received in response to this announcement, only one being of a theoretical nature, the others being based upon practice; and, although several of the papers appeared worthy of serious examination, the committee deemed it advisable to prolong this competition for another year, and admit additional competitors.

THE Cowal District Committee of the County Council of Argyll have decided that, owing to the narrowness of the majority of the roads in the southern section, and to the fact that the use of these by light locomotives or motor-cars will be positively dangerous to the general traffic, no light locomotives or motor-cars will be allowed to run on roads of less breadth than 20 feet over all, and in no case will they be allowed to travel at a greater speed than eight miles an hour. These restrictions apply to the southern section only, the reports of the sub-committees on the other sections of roads not being yet submitted to the Council. What does the Local Government Board say to this?

SAYS the *Birmingham Argus*:—"The motor-cars careering along Birmingham thoroughfares promise to be a serious addition to the dangers of the street. The riders apparently enjoy the consternation and perplexity of pedestrians when they find the noisy machine almost upon them. The rule appears to be to whirl round corners without the slightest reduction of speed. It is quite time the police restrained the ardour of riders who manifest the most reckless disregard for the public safety." It probably does not occur to our contemporary that so-called reckless driving is very much more risky to the driver than to anyone else, and that drivers of motor-vehicles are, as a rule, responsible people not likely to run unnecessary risk.

SAYS the *Financial News* in a recent issue :—"Everything points at the present time to a successful season for the motor-car industry, and not only is there considerable movement amongst the dry bones of the horseless carriage world, but many cycle traders and dealers report that they are receiving inquiries, and in some cases firm orders, for motor-cars, which there is very little reason to doubt will sooner or later be taken up as a sort of alternative or auxiliary branch by many of those who now deal largely, or have in times past dealt largely, in bicycles. A number of serviceable competitions are to be tried this month at Liverpool, and in the meantime great public interest is being displayed in the undertaking, and the motor-car industry should in itself receive a considerable fillip from these arrangements."

MUCH indignation has been created in Richmond by the proposal of the London United Tramways Company to construct a tram line for electric cars right over Richmond Hill, past the Star and Garter, in connection with the scheme to lay down a line from Kew to Hampton Court. It is felt that a string of overhead wires and tall poles on Richmond Hill, as well as the constant passing and repassing of tramcars, must necessarily detract from the natural beauties of the spot. The Richmond and Kingston Corporation will oppose the application to the Light Railway Commissioners for powers, and opposition is threatened from many other quarters. But the scheme is nevertheless receiving a good deal of support elsewhere, principally among the working classes, who will be enabled to travel cheaply and expeditiously to Hampton Court, and memorials in favour of it, which are being taken from house to house by agents of the Company, are being signed very extensively.

SPEAKING of the Easter tour of the Automobile Club, the *Globe* says :—"The tour has proved certain things beyond doubt; for instance, that the motor-vehicle is admirably adapted for pleasure purposes. All the tourists, on the completion of each day's journey, were enthusiastic in their expression of delight with their experiences. The tour has proved, too, that the motor-vehicles are capable of carrying their freight of from two to six passengers over steep gradients, as the route included such well-known hills as the Hog's Back (the first three miles of which were covered in 22 minutes), the Alton Hill, Crowborough Head, and Sevenoaks. It is a new experience to ride over such gradients without the sensation of concern and pity for the unfortunate horses, who usually can only conquer such hills by suffering and distress. But the engine of the motor-carriage, with its tireless and regular pulsation, carries one over these hills without causing any sensation except anticipation of the glorious rush through the air at 14 miles an hour down the other side of the hill, a pace which is in no way diminished when the flat is reached."

MANSFIELD is a flourishing town, but the outlying districts are not readily accessible by railway, and so the principal inhabitants have sensibly resolved to establish a service of motor-vehicles, and a Company has been formed for this purpose. The first automotor vehicle is expected to be in Mansfield in a few weeks' time, and on its arrival it will commence running between the borough and Sutton-in-Ashfield, Pleasley, Mansfield Woodhouse, and Warsop. It will be constructed to carry 22 persons, and in addition there will be a trailing car capable of accommodating a similar number of passengers, making in all a total number of 44. This last-mentioned car will be hitched on to the other as occasion requires. The motor-car will be 17 feet long; the body 5 feet 7 inches in width, and 6 feet 6 inches over all. It will be driven by steam generated by liquid fuel. In construction it will be of the char-à-banc design, two seats across the car providing accommodation for 16 passengers, with room for four on the back seat and two in front. The idea of forming the present Company originated with Mr. F. A. Robinson, The Park, Mansfield, engineer, who has spared neither time nor expense in inspecting the best types of machines at present built.

SOME CONTINENTAL TRIALS OF PETROLEUM*. AND STEAM MOTORS.

COMPARATIVE trials have recently been made at the Brussels Exhibition and at Tervueren as to the working and cost of fuel of light weight petroleum and steam motors. *La Nature* gives an account of this, according to the data furnished by Mr. Max Ringelmann, in *Le Journal d'Agriculture Pratique.* The competition included petroleum motors, semi-portable, of 4 to 6 H.P., and automotors of 8 to 10 H.P.

The Nagel and Hermann motors, of Brussels; the Capitaine motor, of Frankfort; and the Société Française de Materiel Agricole, were amongst the first class of motors.

The Nagel and Hermann motor, set in motion in 9 minutes, furnishes a force of 4 H.P. at 288 revs. per minute and consumes 4·66 lbs. petroleum per hour, of which ·386 lb. are for the lamp, or 1·139 lbs. per H.P. per hour.

The Capitaine takes 7 minutes to be set in motion, and furnishes a force of 4 H.P. at 334 revs. per minute, with a total consumption of 4·7828 lbs. petroleum, or 1·194 lbs. per H.P. per hour.

The Société Française de Materiel Agricole motor takes 12½ minutes, and two men, to be set in motion; at 354 revs. per minute it furnishes a force of 4 H.P. and a total consumption per hour of 4·448 lbs. petroleum, or 1·44 lbs. per H.P. per hour.

The weights of these three motors are respectively 2,310, 1,386, and 1,760 lbs., and their price varies from 2,500 to 2,275 francs.

The locomotives of 8 to 10 H.P. belonged to Messrs. Swiderski, Hille, and La Société Française de Materiel Agricole.

The Swiderski motor, at 274 revs. per minute, furnishes a force of 8 H.P. with a total consumption of 8·518 lbs. of petroleum per hour, or 1·0648 lbs. per H.P. per hour, and was set in motion in 10½ minutes by two men. Its weight is 5,390 lbs., and price 5,000 francs.

The Société Française motor was set in motion in 5 minutes by one man; at 219 revs. per minute it developed 8 H.P. and consumed 7·559 lbs. of petroleum, or ·945 lb. per H.P. hour. Its price is 5,400 francs, and weight 9,600 lbs.

The Hille motor can be set in motion by one man in 11½ minutes. At 240 revs. per minute it develops 8 H.P. and consumes 10·1398 lbs. per hour, or 1·2675 lbs. per H.P. hour. Its weight is 9,350 lbs., and cost 7,000 francs.

The steam automotor section comprises motors of 4 to 6 H.P., made by MM. Lefebre-Albaret, Laursedat, et Cie., and M. A. Raze, and also motors of 8 to 10 H.P. by the former firm.

As regards the former, these give off 5 H.P. at 140 revs. per minute, and consume 24·64 lbs. of coal and 303·6 lbs. of water per hour, or 4·93 lbs. of coal and 60·7 lbs. of water per H.P. hour. The weights vary from 7,040 lbs. to 7,480 lbs., and the cost is about 5,000 francs.

The Raze motor gives off 5 H.P. effective (brake) at 154 revs. per minute, and consumes 28·6 lbs. of coal and 131 lbs. water, or 5·7 lbs. of coal and 26 lbs. water per H.P. hour. The weight is about 7,480 lbs., and cost 5,000 francs.

Motors of 8 to 10 H.P. give an effective power of 8 H.P., and consume per hour 44 lbs. coal and 442 lbs. water, or 5·5 lbs. coal and 55·2 lbs. of water per H.P. hour. They weigh about 9,790 lbs., and cost 6,650 francs.

These trials are interesting, as they show the practical value of the two systems—petroleum and steam—side by side. It may be concluded that petroleum motors of 4 to 6 H.P. consume from 1·1 to 1·3 lbs. of petroleum per H.P. hour, while those of 8 to 10 H.P. consume from ·88 to 1·1 lbs. of oil per H.P. hour. Steam motors of 4 to 10 H.P. consume from 4·4 to 5·5 lbs. coal, and from 55 to 66 lbs. of water.

It is also to be noted that, whereas petroleum motors only require a few minutes to set in motion, steam motors require often an hour.

THE principal event during the past month has undoubtedly been the outbreak of war between the United States and Spain. Should extensive military operations be undertaken, a good opportunity will be afforded of testing the practical value of motor-vehicles as commissariat, baggage, and ambulance wagons, or as tractors hauling these.

* Ordinary burning petroleum, sp. g. about ·8, and flashing at about 100° F.

THE SIMPSON AND BODMAN STEAM VAN.

IN our March issue we published and commented upon the paper read by these gentlemen before the S.P.T.A., giving the results of their experiences with motor-vehicles. The methods of framing, gearing, &c., advocated by them will be gathered from the following description of their van. Their object in designing the vehicle has been to obtain a sufficiently rigid construction and freedom from vibration for the body.

The brackets, b^1, are connected together by the cross bar, b^3. Depending from the bars, a^2, are bearing brackets, a^3, and similar bearing brackets, b^4, depend from the bars, b^2. These bearing brackets, a^3, b^4, are connected to the depending brackets, b^1, by the bars, a^6, and the bars, b^7. The bearing brackets, a^3 and b^4, carry the bearings of the crank-shaft, c; they are also connected together by the tie rod or bar, b^6. Struts or stays, b^5, connect the end bar, a^1, with the lower parts of the bearing brackets. There is a stay, a^4, between the end bar, a^5, and the cross bar, b^3, which is formed of a single steel tube. Upon this stay is fixed a journal, and there is fitted an oscillating bearing, d, which carries the steering wheels axle-tree, d^1. The axle-

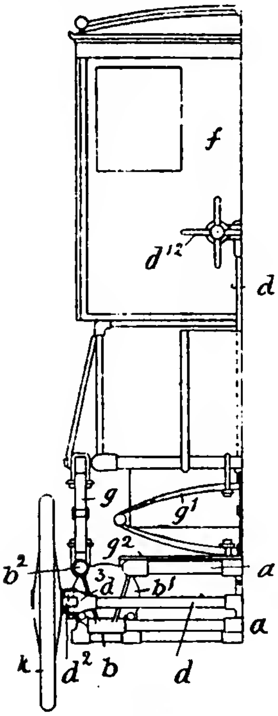


FIG. 2.

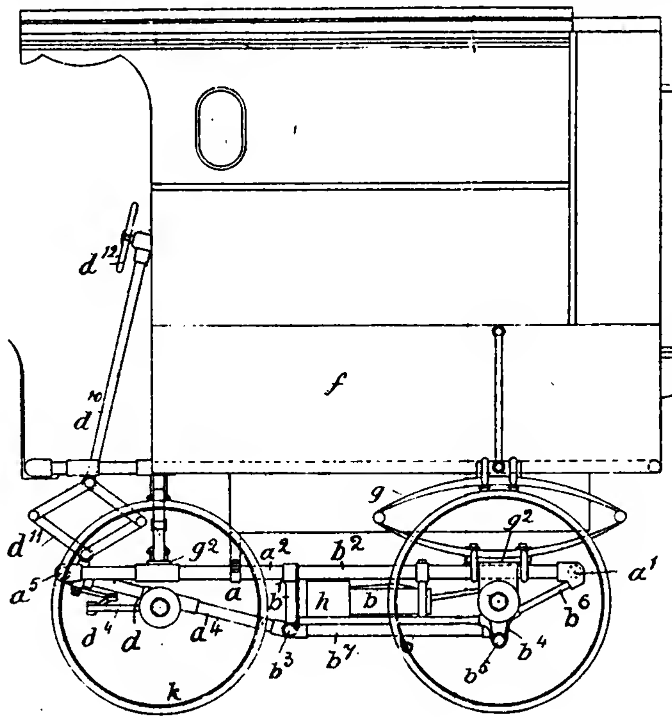

FIG. 1.

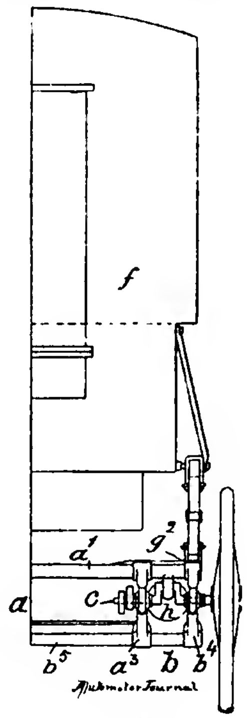

FIG. 3.

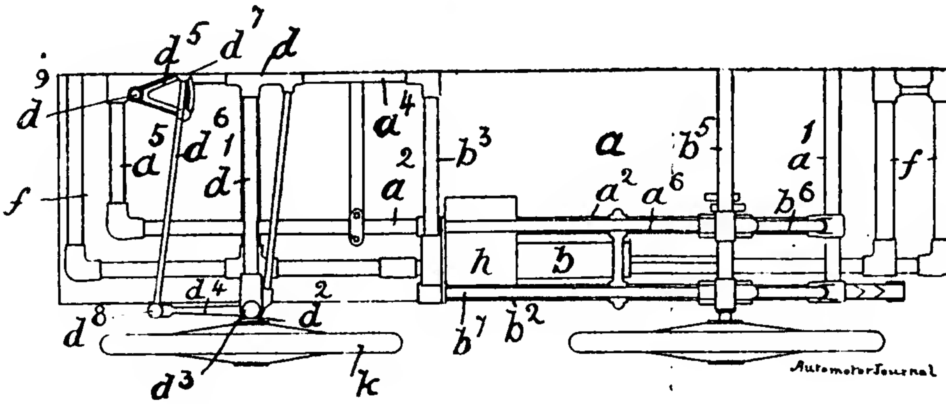

FIG. 4.

Referring to the accompanying drawings, Fig. 1 is a side elevation of the motor-vehicle, Fig. 2 is a half-front elevation, and Fig. 3 a half-back elevation. Fig. 4 is a half-plan of the vehicle looking from the underside. The framework or perch, a, consists of a rectangular trussed frame of steel tubing formed with a wing, b, on each side and extends over the axial line through the wheel centres. The tubing is formed into straight bars and joined together by connecting pieces and brackets made of steel or malleable iron. Each wing, b, is formed by continuing the end bar, a^1, past the side bar, a^2, carrying a bracket, b^1, projecting from the bar, a^2, and connecting each end of the end bar, a^1, with the bracket, b^1, by means of the bar, b^2, in each case.

tree, d^1, carrying the steering wheels, k, is formed of steel tubing, to the ends of which are fitted short axles, d^2, by means of a knuckle joint, d^3. To each axle, d^2, is fixed an arm, d^4, which is coupled with a sector, d^5, by means of a coupling rod, d^6, with knuckle-jointed ends, d^7, d^8. The ends, d^7, of the coupling rods, d^6, cross one another when jointed to the sector, d^5, as shown in Fig. 4. The sector is mounted in a bearing, d^9, and is connected to the steering rod in the steering post, d^{10}, fixed to the body framework of the vehicle by means of the flexible coupling, d^{11}, which steering rod is operated by the hand-wheel, d^{12}, acting through suitable worm or bevil gearing. The body, f, is shown mounted upon springs, g and g^1; the springs,

g, are seated upon the bearing brackets, b^6, and the spring, g^1, is seated upon a transverse bar, g^2, fixed to the side bars, a^2, of the framing The axle-tree, d^1, is trussed by the stays, d^{13}. To the depending brackets, a', are bolted the cylinders, h, which act upon the driving wheels directly the crank-shafts, c, forming also the driving wheels axles.

A RECENT DESIGN IN AUTOMOBILE PHAETONS.

A good deal of what biologists would call "selective process" is observable in the design of mechanically-propelled vehicles. Whether it be that long association with the horse has blunted or perverted our perceptions of what is fitting is questionable; but the fact remains, or rather the impression obtains, that it is exceedingly difficult to satisfy our ideas of elegance in designing horseless vehicles. So conscious are many of our automobilists of this fact that they recognise that this absence of what artists mean by "completeness" constitutes a serious hindrance to the advancement of the industry. And with a view to effecting an improvement, the distinguished automobilist, Sir David Salomons, President of the Self-Propelled Traffic Association, has generously offered a handsome sum for competition in the forthcoming Brussels Races for the best-designed vehicle. Even our French neighbours, who are unsurpassed for elegance in ordinary carriage building, seem to lose their artistic touch when it comes to motor-vehicles. An improvement is, however, noticeable in later designs, and we feel sure that eventually motor-vehicles will be designed that will not as at present remind one of a street omnibus without horses or of a cab being pushed from behind, but will satisfy one's æsthetic and mechanical sense. The vehicle we illustrate herewith seems to us to approach nearer to our conception than many we have seen. It looks natural, and not as though it had lost its horses. Indeed, horses would be in every sense out of place if attached to it. As it is, it does not convey any idea of association with animal traction, but, like a railway locomotive, it is unmistakably an automotor-vehicle. Its appearance is, perhaps, somewhat heavy, but this is due to the thick rubber tyres. In other respects the model is good, the machinery is not too apparent, and there is no reason why it should ever be, but most makers will obtrude chains and pinions to an unnecessary degree. This vehicle is a six-seated phaeton, and has been designed and built by La Société Continentale d'Automobiles, which now carries on the business founded by MM. Gautier et Wehrlé. As will be seen, the motor is placed in front, and consists of two horizontal opposite cylinders using light petroleum, and having a simple carburator, incandescent ignition, and valve gear, the latter being worked by cams in the usual manner. Instead of transmitting the motion of the main shaft by chain gearing, a longitudinal shaft is fitted which, by a most ingenious system of universal joints, transmits the motion to the rear wheels. We shall hope to illustrate this gear, as it seems to present several advantages. The transmission gearing runs in oil, and is very accessible. We understand that no difficulty is experienced in working this gearing under the most trying conditions. The vehicle in the illustration is entered for the Paris-Amsterdam Race, and will no doubt give a good account of itself.

A Recent Design in Automobile Phaetons.

HOW THE ROMANS BUILT THEIR ROADS:

A Lesson to our Municipal Surveyors.

The Romans constructed their main roads to last for ever. They are true monuments, made of siliceous and calcareous materials far superior to the highest type of modern work. The superstructure was a roadway, generally very strongly convex, and two side paths or footways. Near Rome the full width was often 20 metres, but not usually. From 3 to $3\frac{1}{2}$ metres for the smaller roads and from 4 to $4\frac{1}{2}$ metres for the larger are dimensions that have been generally noted. In mountain regions the road was narrowed to a single carriageway, $1\frac{1}{2}$ metres. The sidewalks were large near the cities, but reduced to $\frac{6}{10}$ metre in the outer districts. These were built of cut stone, at least on the border. At every 12 paces (18 metres), mounting stones were placed. At every 1,000 paces (1,481 metres), mile stones were erected. In one instance, the roadway was divided by a low wall down the middle as if to surely establish two streams of traffic.

Some of the best roads were paved with marble. The minor or secondary roads were not so carefully made.

In the construction of the wagon road a ditch was dug to the solid earth, which was stamped or rolled, or even stakes driven if necessary, then, on a floor of sand, 10 or 15 centimetres thick, a layer of mortar was placed, after which they placed successively four layers, as follows:—

Statumen.—The support or foundation. A course of several layers of flat stones, bound by a hard cement, or, failing in that, clay. This layer was usually 30 centimetres thick, and twice that in bad lands.

Rudus.—A concrete of pebbles, stones, or broken bricks strongly stamped together with iron-sheathed stampers. This layer, when finished, was usually 25 centimetres thick. When mortar was lacking, loam was used.

Nucleus.—A layer of 30 to 50 centimetres of gravel or coarse sand, finer than the third layer, and rolled successively in small layers.

Summum dorsum (*summa crusta*).—A convex layer, 20 to 30 centimetres thick or more, made somewhat differently according to the materials at hand. It was either paved with cut stone or laid with pebble and granite or metaled.—*Carriage Monthly.*

The examination of candidates for licenses to ply as automobolists is held in the Rue de Magdebourg, Paris, near the Trocadero. This street has a very steep gradient, worse than the Savoy Hill in London.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to THE EDITOR OF "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. KING AND CO., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents:—*

London: POTTLE AND SONS, 14 and 15, Royal Exchange, E.C.
Wholesale: BRETT AND CO., 5, Pilgrim Street, Ludgate Hill, E.C.

Birmingham: J. MCCANN, 37, Union Street.

Manchester: JOHN HEYWOOD, Deansgate.

Newcastle-on-Tyne: C. C. ROSS, 35, Side.

Paris: HOMÈRE MOREAU, 97, Rue Nollet.

Victoria (Australia): PHILLIPS, ORMONDE, AND CO., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

Proprietors and Publishers—F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

MAY 16TH, 1898.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month.

1898.	
May 16. 23 ..	Society of Arts Cantor Lectures—"Electric Traction," by Prof. Carus Wilson.
May 20 ..	Automobile Club of Great Britain. Visit on motor-carriages to electric lighting stations of Westminster and Kensington.
May 24-27 ..	Self-Propelled Traffic Association (Liverpool Centre) Heavy Vehicle Trials.
May 25 ..	"Concours de Fiacres," Paris. Organised by the Automobile Club of France.
May 27 to June 1	Whitsuntide Tour of the Automobile Club of Great Britain (for details see p. 288).
June	International Italian Exhibition of Motor-Vehicles (Turin).
June 10 to 25..	Motor-Vehicle Exhibition, Paris. Automobile Club of France. Sections—(*a*) Automotor vehicles which have given proof of their practical efficiency; (*b*) Industries connected with automobilism; (*c*) Motors adapted for automotors; (*d*) Vehicles adapted for automotors.
June 15 to July 15	International Concours of Automobile Tricycles and Bicycles in connection with the Turin (Italy) Exhibition.
June 25 and 26	Brussels to Spa Race. Organised by the Automobile Club of Belgium.
July 3 to 11 ..	Race from Paris to Amsterdam, under the auspices of the Automobile Club of France.
July 17 to Aug. 1	Lille (France) Motor-Vehicle Exhibition.
July 30 and 31	Automobile Race, Lille to Boulogne.
August 22 to Sept. 3	Engineering, Machinery, and Motor-Car Exhibition. Royal Agricultural Hall, Islington.
Nov. 18 to 26..	Stanley Show of Cycles, Motor-Carriages, &c. Royal Agricultural Hall, Islington.
1899	Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.
1900	Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

J. HILLICK (Coventry).—The Duryea steering gear is practically the same as Ackermann's.

F. ANDREWS (Liverpool).—The steepest grade in Liverpool is, we believe, 1 in 9, but if you apply to the local municipal engineer's office you might obtain more definite information.

W. W. (Cheltenham).—You will see a description of Houldsworth's speed-gear in Goodeve's "Elements of Mechanism," which is, or ought to be, in every public library.

JAS. CORY (Cardiff).—No. Any formula you see in THE AUTOMOTOR given editorially may be accepted as correct.

JAS. KING (Blackpool).—Ramsbottom's rings are undoubtedly the best for pistons of gas and oil engines.

L. R. C. S.—The firm you name make a good motor, but you would require to have some instruction in handling any one.

WISEMAN.—You are quite right; there is no patent in the Eickemeyer winding, so far as we know. *See* AUTOMOTOR for June, 1897.

OMNIBUS (Gloster Road).—(*a*) We could not possibly be responsible for a thing like this. (*b*) There are some points, including the tyres, which do not conform to the Act, but these are small matters, easily rectified provided the principle of the vehicle is all right.

M. CURRAN (Paddick).—A description of Parsons's steam turbine appeared in No. 9, Vol. I. For a catalogue you had better write direct to Mr. Parsons.

THE VIBRATION OF MOTORS.

PERHAPS the greatest hindrance to the more general employment of light oil motors for the mechanical propulsion of vehicles is the very pronounced vibration that they are subject to. A case came under our notice quite recently, where a colonial buyer declined to place a large order for oil motor-vehicles for no other reason than that his principals would not be able to guarantee their clients against this nuisance. As, under the circumstances, steam and electricity were out of the question, the order for motors fell through. A correspondent writing from Marseilles makes a similar complaint, only in this case it appears that the objection comes from the sex which, it is needless to say, has to be considered if motor-vehicles are to be a success. So far, little has been done to improve the oil motor as generally understood. Numberless patents are, however, taken out for improvements, or for what are called such, in the details of the mechanism, but whether running light or fully loaded the light oil motor is at once noisy and vibratory. It is, therefore, a very long way from being a good piece of mechanism. Noise and vibration mean the useless expenditure of energy in producing them. They also signify considerable outlay on repairs. To the question what causes this vibration we would reply; consider a dynamo, or, better still, a turbine. It is practically, or should be, noiseless; there is no knock and no vibration, yet there is a large mass of material revolving at a very rapid rate. The reason why this rotating mass does not make any noise and does not vibrate or set up vibrations is simply that it rotates around its centre of gravity. So long as this condition obtains the mechanism will not vibrate. In the case in question everything favours the maintenance of this condition; the turning moment is constant, and at every instant the moving weights are symmetrically disposed about the axis of rotation, in which lies the centre of gravity.

Conversely, the condition for vibration is that we shall have a revolving mass whose centre of gravity does not lie always in the centre of its axis of rotation, and this condition obtains in all oil motors and nearly all steam motors in which we have cranks and reciprocating parts. It is especially pronounced in oil motors, inasmuch as in these we find the reciprocating parts, such as the piston and connecting rod, and the rotating parts, such as the crank web, made much heavier than is the case in similar powered steam engines. The reason for this extra weight is apparent, when we remember that in the ordinary oil motor working on the Beau de Rochas cycle there is, as is well known, an impulse at every second revolution. The cylinder, in fact, resembles a gun and the piston the projectile; there is a sudden and violent explosion—that is, the whole energy is transmitted practically instantaneously. It is a question of impact rather than of a gradually applied load, hence the parts have to be made very strong, and we see that large gas-engines resemble, not a little, guns in the thickness of the cylinder parts. The effect of this rapid discharge is to set up an oscillation in the direction of the axis of the cylinder, in fact, the cylinder will vibrate just as does the barrel of a Maxim rapid fire gun when it is being discharged. It is very difficult to suggest any remedy for this kind of vibration of a practical nature. This vibration must not be confounded with that due to the vibration of the reciprocating parts, such as the piston and connecting rod. It is often attempted to correct this latter by masses placed inside the rim of the fly-wheel, but in fast running engines this method is, at any rate, fallacious, and the vibration due to the reciprocating parts is not thereby eliminated. In fact, this vibration can only be corrected by introducing other reciprocating parts suitably designed and placed. We then have to consider the vibration due to the absence of coincidence between the axis of the centre of gravity of the rotating shaft and its crank and the axis of rotation. To correct this masses may be applied to the fly-wheel or to the crank itself. The correction is, however, often rendered difficult by the presence of cams, clutches, &c., on the shaft.

So far as regards the motor, there is no reason why vibration should not be, if not altogether eliminated, at any rate reduced to a very small amount. To do so would, however, entail a considerable modification in existing designs; but it is worth while to trouble over the matter, as it is this unpleasant vibration that hinders the development of the industry. Lastly, there is the vibration communicated to the vehicle by the motor. Very often one can see a vehicle actually trembling. So far as we know, the scientific examination of vehicles of any sort has never yet been undertaken, at any rate not in this country, but should any leisured and wealthy automobilist ever feel a desire to undertake a study of what we may term the physiology of a motor-vehicle, he will find that every motor has some critical speed at which the vibration is a maximum. He will also find that every vehicle has some vibratory "period" at which *its* oscillations are a maximum. If the periods of the motor and the vehicle happen to synchronise, there will be a most pronounced vibration communicated to the latter. Just, however, as it is possible to produce torpedo-boat engines that do not vibrate, so it is possible to produce motors for vehicles that will also not vibrate. At sea, vibration is evidence of imperfect design, either in hull or machinery; it is also evidence of the same thing in motor-vehicles.

THE LIVERPOOL HEAVY MOTOR-VEHICLE TRIALS.

At the time of going to press we understand that all the arrangements have been made, not only for the successful carrying out of the trials, but also for the accommodation and comfort of the various delegates and guests who will attend. Although, as will be seen from the particulars that we published in the last month's issue of The Automotor, the number of vehicles entered is not in itself large, yet this is not by any means a disadvantage, as it will enable the judges to concentrate their attention upon the few rather than to perfunctorily examine the many. Having witnessed the French trials last year, we know that the work involved in observing and tabulating results, if these are to have any scientific value, is by no means light, and we are sure that the judges in the forthcoming trials will have an arduous task, but we are equally sure that it will be efficiently performed. These trials of motor-vehicles will probably be the first ever made in this country of a scientific and practical nature, and they will be watched with great interest from all parts of the world; as in the solution of the problem of carrying fairly heavy loads on ordinary roads, the great difficulty of the economical transport of goods will be overcome, and British manufacturers will not be, as at present, placed at a disadvantage as compared with their foreign rivals.

Coming to the actual details of the competition, we reproduce herewith from our last issue the particulars of the entries:—

ENTRIES.

Class I.—*Minimum load, 2 tons; minimum average speed, 6 miles an hour; minimum platform area, 60 square feet.*

Official No.
7 T. Coulthard and Co., Cooper Road, Preston.
9 Robert Cooke Sayer, 11, Clyde Road, Redland, Bristol.
1 The Liquid Fuel Engineering Company, 20, Abchurch Lane, London, E.C.
2 The Steam Carriage and Wagon Company (Limited), Homefield, Chiswick, London.

Class II.—*Minimum load, 5 tons; minimum average speed, 4 miles an hour; minimum platform area, 110 square feet; floor of platform to be not less than 3 feet 9 inches, or more than 4 feet 3 inches, from ground.*

Official No.
3 The Steam Carriage and Wagon Company (Limited), Chiswick.

Class III.—*Minimum load, 2 tons.*

8 T. Coulthard and Co., Preston.
10* Robert Cooke Sayer, Bristol.
5 The Lancashire Steam Motor Company, Leyland.
6 The L. R. Syndicate (Limited) (Serpollet System), 22, Chancery Lane, London, W.C.
4 The Steam Carriage and Wagon Company (Limited), Chiswick.

The following are the judges appointed:—

From London Council: Sir David Salomons, Bart., President S.P.T.A.; Professor Boverton Redwood, F.I.C., F.R.S.E.

From Liverpool Council: Professor H. S. Hele-Shaw, M.I.C.E., &c.; John Alexander Brodie, Esq., M.I.C.E.; Everard R. Calthrop, Esq.

As reserves the following gentlemen will hold themselves in readiness to act if occasion requires:—S. B. Cottrell, Esq., M.I.C.E.; H. B. West, Esq., M.I.M.E., M.I.N.A.

We understand that the following gentlemen representing the French Automobile Club have signified their attention of being present:—Comte de Dion, Vice-President; Comte de la Valette; M. Pierre Giffard; M. G. Forestier; Baron Rogniat; M. Leon Francq Jeune; M. Louis Lemoine; M. Amédée Vernes; M. André Michelin.

The Comte L. Van den Steen de Jehay has been appointed to represent officially the Belgian Automobile Club.

The War Office has selected the following officers to officially attend and report upon the trials:—Major R. L. Hippisley, R.E.; Captain J. A. L. E. Johnstone, R.E.; and Captain H. F. Gaynor, R.E.

Appointed by the Duke of Norfolk, Postmaster-General—Mr. Francis Salisbury, Postmaster of Liverpool.

Deputations are expected to attend from the Corporations of Hull and Wolverhampton.

In Liverpool, the following Associations have appointed as delegates:—Corn Trade Association—Mr. John Blyth; Cotton Association—Mr. Danson Cunningham (Vice-President), Mr. R. W. Brown; Cart-Owners' Association—Mr. R. Proctor (Chairman), with a committee of 12 members; Timber Trade Association—Mr. R. R. Lloyd (President); Chamber of Commerce—Deputation of Light Railway Commissioners; Salt Chamber of Commerce—Mr. H. John Falk (President).

The general arrangements are:—

1. During the trials all communications to be addressed to the Adelphi Hotel, where the headquarters of the Association will be.

2. The depôt for heavy vehicles, from which the starts will be made, is the Dockyard, at the south-west corner of the Prince's Dock, adjoining the Riverside Station.

3. Light carriages will be provided to enable those desirous of witnessing the trials through to follow the runs. Seats may be booked at 10s. each per day. Tickets (transferable) for the four days £2 each. Early application is recommended. All seats will be numbered, and the carriages will be in the charge of experienced motor men.

* We understand that this is an electrical vehicle.

4. A dinner will be held at the Adelphi Hotel on the evening of Thursday, May 26th, 1898. It is expected that the Right Hon. the Earl of Derby, K.G., will preside.

5. All persons attending the trials must wear the official rosettes to secure admission to the depôt, &c.

6. Further particulars may be had from Mr. E. Shrapnell Smith, Hon. Local Secretary, and organiser of trials.

Address—To May 21st, Royal Institution, Liverpool.
During trials, Adelphi Hotel, Liverpool.

Maps of the routes to be traversed, giving gradients and other topographical information, together with halting places, depôts of fuel and water, will be supplied to competitors and visitors.

We may add that the honorary organising secretary of the Liverpool Centre, Mr. E. Shrapnell Smith, will gladly supply information of every kind to intending visitors, and both he and Mr. Andrew W. Barr have arranged to attend during the whole period of the trials, and in every way ensure their success.

THE BRITISH MOTOR SYNDICATE.

We understand that the actions brought by a number of shareholders in this Company have finally been compromised by those interested. No doubt our readers will recollect the series of articles which we have published from time to time upon this subject, and the views which we have enunciated thereon, none of which we have changed in the smallest degree. We regret that this compromise should entirely destroy all prospect of the methods in connection with this Syndicate being made public, because, not being in possession of the details of the settlement, which appear to have been kept particularly secret, it is difficult to judge whether the shareholders have been well advised in closing the pages of what promised to be a very interesting book on the art of company work. If the shareholders have determined to let bygones be bygones and have received a fairly satisfactory quittance, we have no further right or wish to battle on their behalf. Although desperate cases require desperate remedies, at the same time we quite agree that it is often a mistake to throw good money after bad, and so long as the individual shareholders are satisfied we are personally glad to know that this ugly sore, which has, with others, been one of the chief hindrances to the progress of automobilism, has been healed. In this matter we have avoided as far as possible any personal reference, always endeavouring to deal with the schemes in the abstract, and whilst recognising that Mr. H. J. Lawson, outside the financial question, has been instrumental in introducing automobilism to the British public, it is to be regretted that this in itself good object should have been associated with financial methods of a distinctly questionable character. The majority of the investing, or perhaps it would be better to say speculating, public rarely investigate; they follow a leader like sheep, and hence they nobly subscribed for projects in automobilism which can never be realised, and which those of us whose business it is to know these things foresaw were doomed to failure. Thus not a few investors thought that light oil or spirit motors would be used for heavy traffic, and hence subscribed for the purchase of this class of patent. It is now recognised that not only is the use of oil motors restricted practically to purposes of light traffic, but that should some of the suggested legislation relating to petroleum ensue, the value of motors, or the patents relating thereto, will depreciate enormously. However, if the members of the British Motor Syndicate are satisfied with their assets and with their undeniably able chairman, we can only congratulate them on their gracefully modest reticence and prudence which has led them to wash their financial linen in the seclusion of their own offices rather than in public. From what we know, we should not be surprised to hear that the Great Horseless Carriage Company's dissenting shareholders are also quietly "compensated."

WIND PRESSURE.

To say that the wind exercises an influence upon the motion of nearly all moving bodies is to state a truism familiar to everyone, and after every heavy gale we have ample evidence of the fact in the chimney-pots, tiles, telegraph-wires, &c. that get displaced, and in the wreckage that strews the sea-beach. Of the actual pressure of the wind, or rather of the action of the wind, little that is accurate is known, and two similar instruments properly tested will often give dissimilar results when but a little distance apart. Neither are we agreed as to the exact relation existing between velocity and pressure. It is, indeed, very difficult to measure either the velocity or the pressure; thus in the tests made of the wind force during the construction of the Forth Bridge it was found that large instruments would give readings different from small ones, although both were apparently exposed under the same conditions. The question of wind pressure is of rather more interest and importance to the architect and civil engineer than to the automobilist; but inasmuch as aeronautics is but a form of automobilism, and inasmuch, also, as under certain conditions the wind pressure adversely affects automotor vehicles, we give the following information:—

The pressure of the wind is, it is generally agreed, expressed with tolerable accuracy, sufficient for all practical purposes, by Hawksley's formula—

Let v = velocity in feet per second;
h = height through which a body must fall in order to generate a velocity, v;
w = weight of a cubic foot of air = ·0765 lb.;
g = acceleration of gravity.

Then—

$$h = \frac{v^2}{2g}.$$

And since p, the pressure of a fluid striking a plane perpendicularly, and then escaping at right angles to its original path, is that due to the height, h, we have—

$$p = \frac{wv^2}{g}.$$
$$= \frac{\cdot 0765\, v^2}{32}.$$
$$= \left(\frac{v}{20}\right)^2 \text{ (nearly).}$$

From this formula is constructed the following table:—

Velocity in feet per second, v.	Velocity in miles per hour.	Pressure in lbs. per square foot.
10	6·8	0·25
40	27·2	4·00
70	47·6	12·25
100	68·0	25·00

If the pressure is applied to an inclined surface, then the effective pressure, p_e, will be—

$$p_e = \left(\frac{v \sin \theta}{20}\right)^3$$

where θ is the internal angle made between the direction of the wind and the plane surface.

A somewhat similar table will be found on p. 21 of THE AUTOMOTOR POCKET-BOOK.

THE SCARBOROUGH ACCIDENT.

We give the salient facts of this deplorable affair elsewhere. If, however, automobilists take the lessons it conveys to heart much good will be done. The moral of the thing seems to be that in motor-vehicles two things are absolutely indispensable if automobilists wish to avoid unpleasant and distressing occurrences such as the one in question. The first is the driver must be possessed of plenty of nerve, and not afraid to incur personal injury if by so doing he can avoid injuring others; secondly, the brake power must be more than ample—it must be capable of absorbing the whole kinetic energy of the vehicle. As regards the first this is a matter of employment, but having regard to the legal obligations that may be incurred we think too great care can hardly be displayed in selecting a good driver, and we should prefer a man who had not been a fitter or engineer but who was accustomed to street traffic and who had nerve and intelligence. Working day after day at an engineer's bench does not give one the knowledge or experience of handling a vehicle in a crowded street. We do not say that the Scarborough accident was due to any incompetence on the part of the driver, but it would seem that either he did not do all that was possible as regards manipulating the machinery or else the vehicle was in a very defective state.

From the published account of the accident it would seem that one of the driving chains parted, and hence until the engine was stopped there would be a tendency for the vehicle to run round and round; this might be partially but not wholly checked by the steering gear. In the absence of any accurate data relating to the vehicle we, however, hesitate to express any opinion upon this head. Of course there was but one thing to do, and that was to instantly stop the motor and brake the wheels. As, however, the former was not apparently done and the gear of the latter was broken, and the second brake does not appear to have been used, the vehicle pursued an erratic course and in going down a gradient developed, as a local scribe picturesquely but unscientifically says, a tremendous impetus—whatever that may be. It does not seem to have occurred to the driver that there was still another expedient and that was to throw on the reversing gear even at the risk of stripping his wheels. However, after fatally injuring a pedestrian the vehicle was stopped. As regards the second point, we doubt whether the brake gear of motor-vehicles is as powerful as it might or should be. By Article II, Section 4, of the Local Government Board Regulations, the light locomotive is to have two independent brakes of such efficiency that the application of either shall cause two of the wheels on the same axle to be held so that the wheels shall be prevented from revolving. Whether this means from revolving under all circumstances or whether it means after the motive power is cut out we do not know. We, however, think that a good brake for motor-vehicles should be capable of preventing the wheels from revolving under all circumstances such as when on a descending gradient under full power. We were consulted on this head some time ago and advised that this should be specified—the manufacturer would not, however, have it, as he said it could not be done. Every one has, however, observed that on railway trains it is the commonest occurrence to see the wheels so effectually braked that they are prevented from revolving although the train is in motion. On railways the adhesion is never very great, being but one-fifth to one-seventh of the weight on drivers of the motor-vehicle (the locomotive). On road motor-vehicles with iron tyres and on macadam roads the adhesion is at least one-half the weight on drivers, and hence, by effectually braking the wheels, the vehicle could be stopped in a very short distance. Let us consider the case of a vehicle weighing, in working order, $W = 2$ tons; let the weight on drivers be two-thirds of this, or $w = 3{,}000$ lbs.; taking the co-efficient of adhesion, $\mu = \frac{1}{2}$, then the greatest pull, P, the motor can possibly exert will be $\mu w = 1{,}500$ lbs.; let R be the resistance in pounds per ton due to the road; v the velocity in feet per second while the vehicle is traversing a space s feet; let $l - s$ be the distance in which it is required to stop the vehicle by calling up a brake resistance of R^1 lbs., while the vehicle is in motion it will develop a kinetic energy of $\frac{1}{2} W v^2 / g$; suppose it is going at the rate of 15 miles per hour = 22 feet per second, then the kinetic energy will be 34,500 foot lbs., and the equation of motion will be—

$$\tfrac{1}{2} W v^2 / g = (P - R)\, s = (R + R^1)\,(l - s).$$

Confining ourselves to the right hand expression, and making $l - s = 50$ feet, say, and putting $R = 120$ lbs., we easily find that $R^1 = 570$ lbs. Similarly, if we wish to stop in a distance of 20 feet we must have a brake resistance of 1,600 lbs., in order to dissipate the kinetic energy. From these figures it will be seen, that in order to call up a resistance of half a ton something more substantial than thin iron rods and light bell crank levers are necessary. In short, to obtain full control over a motor-vehicle powerful screw hand gear, modelled after railway practice, is, we think, essential. This, however, implies that the axles must be carried between horn plates. Brake tests and the actual distances a vehicle will run under various conditions have never yet been made, so far as we know. In fact, though vehicles have been used for so many centuries yet little is known of the science of road automobilism. We hope brake tests will form part of the programme at the forthcoming trials in Liverpool, as the heavier the vehicle the more necessary it is to have good braking power, and it is also to be hoped that the Scarborough accident will lead automobilists to pay some attention to the matter, as our own observation convinces us that the majority of motor-vehicles are deficient in this respect.

REVIEWS OF BOOKS.

The Engineering Magazine.—The April number of this magazine is interesting to automobilists for at least two articles, although neither deal with that branch of the subject with which the majority of our readers are more particularly concerned with. At the same time automobilism covers such a wide field and the same appliances for locomotion are used under such different circumstances that even those who simply wish to eliminate the horse will find many useful "wrinkles" in studying what is being done in other directions in this what we term the noble art of automobilism. Dredgers are examples of automotors which are in a humble and prosaic way improving old harbours and ports, and Mr. Corthell discusses them as an expert and his contribution is a most useful and interesting one. In the gearing used on board these craft there is much in principle that is worth study by those who design motor-vehicles. Both kinds of automotors use chain gearing, for example, under bad conditions as regards the life of the chain.

"Notable Speed Trials of British Locomotives," by that distinguished authority, Mr. Rous-Martin, is an attempt to set at rest the much-debated question of the speed of locomotives, and we find that even in 1848 speeds of 1 mile in 46 seconds had been reached. On many of our newer locomotives speeds of 1 mile in 42·3 seconds are easily attained, while 1 mile in 41·8 seconds has been reached in other special express engines, while in the Jubilee Year on a Midland express engine Mr. Rous-Martin did 90 miles per hour. He concludes by declining to believe that, contrary to what many engineers think, a maximum has yet been reached. The article is well illustrated and is good reading. Another article of interest to makers and users of small high-speed motors is entitled the "Steam-Engine and the Dynamo," by Mr. Charles T. Child. In "The Gas-Engine in American Practice," we find a good account of what is being done on the other side in developing a rather neglected form of motor. There is a good description of the Diesel engine, but the Kane-Pennington motor, of which so much has been said, does not appear to commend itself to Mr. Child.

In the May number of this magazine there is again much matter of considerable importance to automobilists. We have frequently insisted that for heavy vehicles automobilists cannot do better than follow, within, of course, limitations, torpedo-boat practice. We are limited as to weight and so are torpedo-boats. Mr. John Platt describes the development of the torpedo-boat destroyer, and rightly describes these vessels as being a marvellous concentration of power and speed. Naturally the firms of Thornycroft and Yarrow come in for much mention. As is well known, the former firm are actively developing their motor-vehicle business and are embodying in their mechanism many of the features that they so successfully have employed in torpedo-boat practice. "Railroad Fares and Passenger Travel," by Mr. H. G. Prout, is an instructive attempt to solve a very intricate problem. Those of our readers interested in light railways and in establishing lines of other motor-vehicles will find here some points worthy of consideration. Mr. Corthell continues his account of sea dredgers, to which we have before alluded. Perhaps the most useful article is one by Mr. J. B. Starwood on the "Economical Use of Steam in Non-Condensing Engines." As steam motor-vehicles use small non-condensing motors, and as these are extremely extravagant in their consumption of coal or other fuel and water, every information which will enable makers and users to improve them is to be welcomed. As we intend to reproduce this article we need say nothing further at present.

Other articles are:—"American and English Architectural Steel Construction," by Mr. C. V. Childs; "An Effective System of Finding and Keeping Shop Costs," by Mr. Henry Roland; "The Purification of River Water-Supplies," by Mr. Allen Hazen; "Applications of Electricity on a Modern Warship," by Mr. George H. Shepard; and "Tank Irrigation in Central India," by Mr. George Palmer.

"SCIENCE and Engineering, 1837-1897."—This is an interesting little *brochure*, written by Mr. Chas. Bright, the son of the late distinguished submarine cable engineer, Sir Chas. Bright. It gives in a popular and condensed form a *resumé* of the scientific inventions that have been made in the Victorian era. As a cable engineer, Mr. Bright naturally deals with telegraphy more fully, but his remarks on other subjects are not less readable. Curiously enough nothing is, however, said of road automobilism. Surely there have been some useful inventions in this branch of applied science? The work is published, without any preface or introduction to explain its *raison d'être*, by Messrs. A. Constable and Co.

La Revue de Méchanique.—The April number of this is to hand, and as usual it contains a number of high-class articles. There is an excellent report of the Commission appointed by the Municipality of Paris to examine into the smoke nuisance and the means for its suppression. An exhaustive analysis on the vibration of engines and ships is made by M. Haas, of the French Navy; this we can certainly recommend to the notice of makers of motor vehicles, especially those who manufacture oil motors. Another good article is on pumps by M. L. Masse, in which the principal and most used pumps are described and illustrated.

"ACETYLENE GAS: its Nature, Properties, and Uses; also Calcium Carbide," by Mr. G. Thompson, consulting engineer, Liverpool. This is the title of a forthcoming work on a subject of growing importance and of great industrial possibilities. It is by a distinguished and well known engineer, and hence should be authoritative. We hope to review it in our next number.

WE have also received:—*The Journal of the Society of Arts, The Indian Engineer, Industries and Iron, The Practical Engineer, Coach-Builders' and Wheelwrights' Art Journal, The Journal of Acetylene Gas Lighting, Knowledge, Machinery Market Review, The London Chamber of Commerce Journal, Indiarubber World, Cyclist, Scottish Wheel, Irish Field, The Yachting World, The Engineering Magazine, La Revue de Méchanique, La Locomotion Automobile, La France Automobile, L'Industrie Velocipédique et Automobile, L'Automobile Illustré, La Moniteur Automobile, La Revue des Transports Parisiens, Les Sports, L'Energie Électrique, Der Motorwagen, Samokat, Horseless Age, American Wheelman, The Motocycle, Australasian Coach-Builder and Saddler*, &c., &c.

CATALOGUES.

THE United Ordnance and Engineering Company (Limited), until lately known as Messrs. Easton, Anderson, and Goolden, send us their catalogue of continuous current dynamos and motors. While for lighting and power these machines have a deservedly high reputation, we do not observe any mention made of motors suitable for electric traction. Indeed, it is rather a matter for regret that hardly any British firms seem to manufacture such. Most of the motors we have seen in vehicles are either of United States or Continental make, yet there is a good opening for a British-made article. In addition to the purely commercial information as to prices, &c., a good deal of technical information as to the calculation of horse-power, &c., is given. This will greatly facilitate the task of selecting a machine by a customer.

THE latest catalogue of the Daimler Motor Company contains illustrations, descriptions, and prices of their now well known vehicles. We observe that they make no less than 11 distinct types of vehicles, all having 4 H.P. motors and four speeds, the lowest of the latter being 2·2 and the highest 16·6 miles per hour. As these vehicles are very carefully built their price is naturally high, but it is undoubtedly cheaper in the long run to pay a good price for a good article than to take out the balance in frequent repairs. So far as our experience goes, these vehicles give great satisfaction if used intelligently.

GOOD clutch gear is an essential for motor-vehicle mechanism, and among the many forms of friction clutch, that by Messrs. Heywood and Bridge, of Salford, is well suited for this and kindred purposes, or indeed wherever a machine has to be started and stopped many times. This firm have forwarded us a descriptive pamphlet of their patent friction clutch, and we gather it is successfully applied to such diverse motors as rolling mills and electric-lighting engines. If a clutch will stand the former it will stand anything.

MESSRS. J. BAGSHAW AND SONS (Limited), of Batley, Yorks, have sent us a copy of their new catalogue, which contains particulars of the shafting, pulleys, plummer blocks, &c., manufactured by them. Among other specialities we notice clutches and wheel gearing suitable for motor-vehicles. There is also a good practical chapter on power transmission.

MESSRS. HOLDEN AND BROOKE (Limited), of Manchester, make an exceedingly effective automatic injector which we think would prove invaluable in steam automobilism, as it would obviate the necessity for a feed pump. In their catalogue this is fully described, and also the method of fixing and using it. They also make a simple reducing valve which would also be applicable to motor-boilers using high steam.

MESSRS. SMITH, PARFREY, AND CO. send us their price list of wheels and fittings for vehicles of all sorts. This old-established firm is laying itself out to meet the wishes of automobilists, and make a special line of wheels, &c., for motor-vehicles. As their experience with vans and omnibuses is so large, they should be well able to advise on the most suitable kind of wheel to adopt.

THE Ardwick Engineering and Machine Company, of Manchester, make, in addition to other specialities, small motors eminently suitable for motor-vehicles, and also lay themselves out to develop the ideas of inventors. In their latest catalogue we observe illustrations and price lists of some neatly designed steam-motors, and they also include a useful chapter on the management of them. Another chapter on useful data will be of service to amateurs in fixing general dimensions, &c. Altogether a most useful catalogue.

WE have received a sheet giving drawings and particulars of Weatherill's anti-vibrating springs and connections for motor-vehicles. Vibration in these vehicles is such a common and unpleasant feature that any means that will lessen it is to be welcomed, and no doubt if these fittings were better known they would be more generally used.

AMONG the really scientific firms of manufacturing machinists few hold a higher position than that of Mr. Jas. White, of Glasgow, who manufacture the very scientific instruments invented by Lord Kelvin. A catalogue of these instruments of precision is interesting and instructive in itself. Although most of the instruments are connected with electrical work, yet many, such as tachometers, indicators, counters, are of use to the automobilist. Needless to say that the goods turned out by this firm are of the very highest excellence.

THE Kelham Rolling Mills Company, of Sheffield, send us a description of their specialities in tyres for motor-vehicles. These tyres are made to any section and fitted with rubber by a new and ingenious process.

THE HEILMANN LOCOMOTIVE.

IT is very generally admitted that the present type of locomotive cannot be much, if at all, improved. On the other hand, the tendency is in the direction of hauling heavier trains at higher speeds, requiring, of course, much more powerful engines. It is a defect with the ordinary locomotive that at high speeds, owing to the method of imparting motion to the driving wheels, very serious oscillations are set up; while at still higher speeds the increase of back pressure in the cylinders causes the power to fall rapidly. Again, in order to haul heavy loads great tractive power is necessary, but while for low speeds this is easily attained by coupling the wheels, for high speeds it is not practically possible to couple more than two, and as the revolutions cannot be high these coupled wheels have to be of large size. For these reasons the problem of hauling heavy loads at high speeds cannot be solved by ordinary locomotives.

It is the distinguishing feature of electric traction that the turning moment on the driving axle is constant, while the speed of revolution can be as high as we want, and any desired tractive effort can be obtained by increasing the number of axles and attaching a motor to each. The power imparted to the motors can be derived either from a central rail, an overhead wire, storage batteries, or, lastly, it may be generated on the locomotive itself. Inasmuch as weight is necessary in order to obtain the proper adhesion of the wheels, and for other reasons, the latter system is preferable. Such, in brief, is the principle of electric railway traction most likely to be adopted on existing railways, and to M. Heilmann belongs the credit of having been the first to apply this principle in a practical manner. About four years ago he designed and built an electric locomotive, called the "Fusée Electrique"; this was tried on the Chemin de Fer de l'Ouest, and it easily hauled trains of 200 tons at a speed of 66 miles per hour. So satisfied were the directors with this performance that arrangements were made for the construction of a still larger and more powerful locomotive on this system. This we illustrate in the accompanying drawings. Fig. 1 is a general view of the locomotive with a van attached. As will be seen, the funnel is in the rear, while the front part of the locomotive is plated into a shape something like a warship's bows. The locomotive consists of two distinct portions; the front part forms the engine room, in this are placed the engines and dynamos which generate the current; the rear part comprises the boiler, tanks, bunkers, &c. The whole is carried on deep web girders, which, in their turn, are carried by two eight-wheeled bogies. In the front part are placed six compound Willan's engines, all on one bed plate, and all driving on to one main shaft, the total I.H.P. being 1,350. Six cylinders were employed, so as to obtain an exactly perfect balance of the reciprocating parts. To each end of the main-shaft is coupled direct a six-pole series wound dynamo, the field magnets of which are excited by a smaller dynamo. When running at the normal speed of 400 revs. per minute the armatures of the large dynamos give off 900 ampères at 400 to 450 volts. The current is distributed to eight motors, one on each axle, thus each wheel is used for adhesion, and slipping is impossible while the full tractive effort is obtained.

Fig. 1.—Heilmann Locomotive (General View).

Fig. 2.—Heilmann Locomotive (Elevation).

Fig. 3.—Heilmann Locomotive (Plan).

The boiler is of the Lentz type, and has 351 tubes and 1,990 square feet of heating surface, and will easily evaporate 29,700 lbs. of water per hour.

The total length of the locomotive over all is 52 feet; the wheel base being 37 feet. In working order it weighs 115 tons. It can haul loads of 200 tons at speeds varying from 90–120 miles per hour, and we believe that it is owing to considerations regarding the permanent way that the full power of this locomotive has not yet been utilised. So far the trials have been highly satisfactory, and M. Heilmann has abundantly demonstrated the correctness of his electrical system of traction.

KINGDON'S STEAM VALVES.

EVERY improvement in small steam-motors suitable for automobilism is to be welcomed, as in vehicles especially is it very necessary to combine as high an efficiency as possible with small size, weight, and cost. Messrs. Simpson, Strickland, and Co., of Dartmouth, who have for many years maintained a very high reputation as builders of Admiralty steam launches, have brought out a compound steam-motor, which embodies several improvements—the inventions of Mr. G. Kingdon.

These improvements consist in the arrangements of the valves and piston-rods, and, as will be seen, one slide valve regulates the steam admission to both engines, so that exhaust steam from the high-pressure cylinder passes through the valve to the low-pressure cylinder at each stroke, and is then used before going to the condenser or atmosphere. Another improvement is that whereby a gland between the two cylinders is dispensed with. Referring to the accompanying drawings (Figs. 1 and 2), *A* is a valve formed with a large port or aperture, *B*, of sufficient width to serve for both the ports, *H*, *D*, in the high-pressure cylinder, and communicates with a passage, *C*, and ports, *B'*, *B''*, which correspond during the movements of the valve with the low-pressure cylinder ports, *F*, *F'*. Steam from the boiler enters the steam chest at *R*, and is thus distributed; with the pistons at the extreme top ends of their stroke, the valve, *A*, is just moving down to uncover the port, *H*, to the steam chest and admits live steam to the top side of the high-pressure piston, *I*, and opens communication between the under side

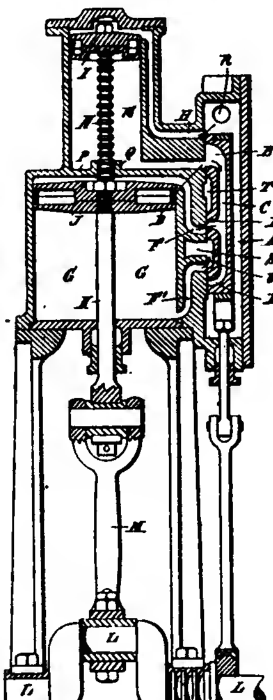

FIG. 1.

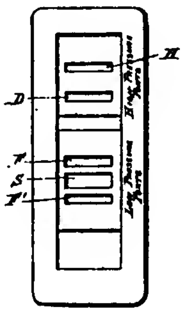

FIG. 2.

of the piston and the top of the low-pressure piston, *J*, by means of the wide port, *B*, passage, *C*, ports, *B'*, and *F* respectively to exhaust the steam from the cylinder, *E*, for further work upon the piston, *J*, the port, *B''*, being closed upon the face of the cylinder. The valve, *A*, is at the same time commencing to uncover the exhaust port, *S*, for exhausting the steam from the under side of low-pressure cylinder to the condenser, or atmosphere, as the case may be, through the cylinder port, *F*, and valve port, *U*. When the pistons, *I*, *J*, have arrived at their extreme lower position, the valve, *A*, will begin to uncover the port, *D*, to the steam chest for admission of live steam, the recess, *T*, being formed for this purpose, and the port, *B*, will open communication between the top side of the high-pressure cylinder, *E*, and underside of the low-pressure cylinder, *G*, through the ports, *H*, *B*, *C*, *B''*, and *F'* respectively, *B'* being closed upon the cylinder face. The top side of the cylinder, *G*, will also communicate with the condenser or atmosphere through the cylinder port, *F*, valve port, *U*, and exhaust, *S*, and so on consecutively. Both pistons are connected to the same rod, *K*, to actuate the crank-shaft, *L*, through the connecting rod, *M*, in the ordinary manner.

Fig. 3 is a sectional elevation of an equilibrium tubular valve arranged as described for the friction valve shown in Fig. 1, the

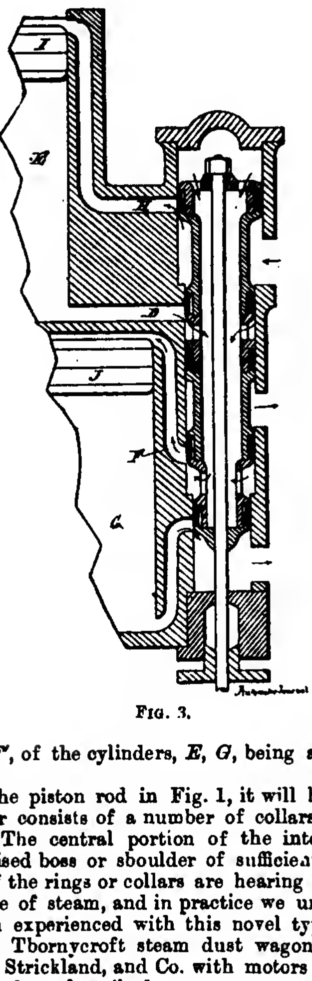

FIG. 3.

ports, *H*, *D*, *F*, *F'*, of the cylinders, *E*, *G*, being also arranged in a similar manner.

Referring to the piston rod in Fig. 1, it will be seen that it is grooved, or rather consists of a number of collars turned out on a single rod, *K*. The central portion of the internal cover, *P*, is formed with a raised boss or shoulder of sufficient depth that never less than three of the rings or collars are bearing against it. There is thus no leakage of steam, and in practice we understand that no trouble has been experienced with this novel type of gland. We believe that the Thornycroft steam dust wagons are supplied by Messrs. Simpson, Strickland, and Co. with motors fitted with valves and piston rods as here described.

Company Promotion in Germany.—In Germany there are two forms of limited liability companies, one the "Aotiengesellschaft," with shares to bearer, and the other, "Gesellschaft mit beschränkter Haftung," with registered shares in capital, which latter is now taking the place of the "Commandit" or of the "Geworkschaft," a very common system of conducting mining operations, one which has no fixed amount of capital, but where it is called in as required by the board. Formerly such companies had unlimited liability, that is, each member of the partnership was liable for every penny he possessed, whereas now the liability is limited to the amount of money called up or paid; should the partner fail to pay, be may have to sacrifice his share, or at least the difference of what it may fetch at public sale on the open market, and the actual cost price or amount already paid up. The first-mentioned class of company is generally floated by bankers of high standing, men of mark, who place the shares amongst their clients. The professional promoter, underwriter, as known in England, is conspicuous by his absence in Germany; hence, says a Foreign Office report on German trade, the dead weight of promotion capital does not exist in that country.

THE KRIÉGER ELECTRIC CAB.

IN THE AUTOMOTOR for March, 1897, we described the Kriéger system of electric propulsion for vehicles, chiefly cabs, carriages, &c. Commencing some years ago with an ordinary horse-drawn cab, M. Kriéger has gradually developed a system of electric propulsion which not only differs materially from other systems in use, but which also possesses some points of marked superiority to them. Briefly, in M. Kriéger's system the driving power is applied to the fore-carriage by means of an electric motor geared to each wheel.

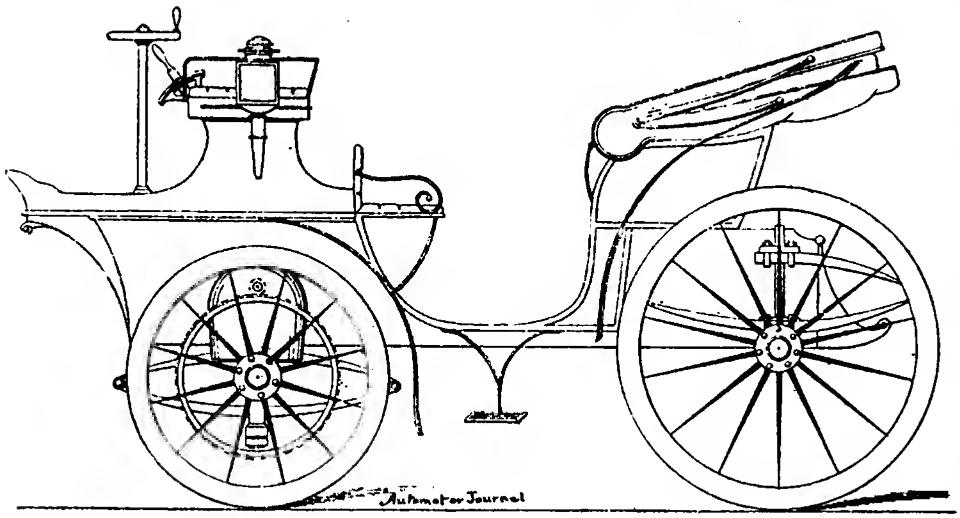

FIG. 1.

To the armature shaft of each motor is attached a pinion with helical teeth engaging with a similar wheel rigidly attached to the corresponding driving-wheel. The ratio of gearing is as 1 to 10. The field magnets of the two motors are coupled in series, and the two armatures in parallel. The use of an independent motor to each driving-wheel enables the steering to be effected electrically. For instance, if the armature of the motor on the inside of the curve it is desired to traverse be short circuited, the fore-carriage will turn to that side. The short circuiting is brought about by means of a special commutator arranged for this purpose. The fore-carriage turns to an angle equal to that made by the steering handle. Hand-steering gear of the usual type is also fitted to the carriage, the whole electrical apparatus constituting an electric servo-motor of a most ingenious kind.

Not content with the success which attended the vehicles built up to last year, M. Kriéger has continually improved upon them, and his latest model, the "Milord" coupé of 1898, which we illustrate herewith (*see* Fig. 1), contains several improvements worth describing. It will be noticed by those familiar with the Kriéger carriages that the driver's seat has been lowered, and the electric gearing of the fore-carriage motor sufficiently reduced to give all the necessary elegance to the vehicle. The mechanical and electrical arrangements are on the same principle as those described by us in THE AUTOMOTOR of 1897, the proportions only having been changed in accordance with long experience.

The weight of the new carriage "Milord" is 2,530 lbs. when empty, and with four passengers and the conductor it weighs about 3,300 lbs. The average speed is 11 miles per hour (a speed really guaranteed), the maximum speed being 15 miles per hour. One can cover about 50 miles of average road without recharging the accumulators; the carriage can thus run the whole day around any given town, and even traverse a very long road before it would be necessary to return to the place where it has to be recharged.

The new battery of accumulators is composed of 44 Fulmen elements weighing 1,012 lbs., and storing up a useful energy of 12 kilowatts, corresponding to the average length of road just mentioned of 50 miles. The weight of the motors is 286 lbs., the efficiency of the motors and transmission being 82 per cent. Six different speeds, of 3, 5, 6·6, 9·6, 12, and 15 miles per hour, are obtained by the manipulation of a single commutator or controller placed within the reach of the conductor's hand. The motors and the gearing are completely sheltered from dust in a box made of sheet iron, as shown in the drawing, above the steering axle in front. The ratio of motor gear to the wheel is 17 to 1 (helical gear).

The frame is made of wood, and carries the tray of the battery. The box is completely separated from the frame, from which it is supported by strong springs. The conductor has two brakes, one (electric) acting on the motors in front, and the other (a rolling brake) fixed on the rear axle. The wheels are fitted with Michelin's pneumatic tyres. The motors, specially constructed by MM. Postel and Vinay, yield 3 H.P., at 2,500 revs. per minute.

The Electric Cab Society Club (Kriéger's system) are at present building a number of cabs which are going to be tried by the Compagnie Générale des Petites Voitures; this type we illustrate in Fig. 2. They will be designed to run an average distance of 40 miles per day in Paris. The accumulators will be recharged during the night. It is said that a saving of more than 40 per cent. will be effected over cabs drawn by horses.

Exhibition of Acetylene Apparatus.—The Executive Council of the Imperial Institute has on foot a scheme for holding an exhibition of acetylene gas generators and illumination by acetylene gas. The generators admissible are divided into three groups, viz., (1) those in which the gas is generated by water being allowed to drip, or flow in a small stream, on to the top of the carbide; (2) those in which water rises round the carbide; (3) those in which the carbide falls into the water; these being again subdivided into automatic and non-automatic. Forms were sent out for applications for space, the Council of the Institute not undertaking to hold the exhibition unless there was a sufficient number of applicants to cover the actual outlay which will be involved.

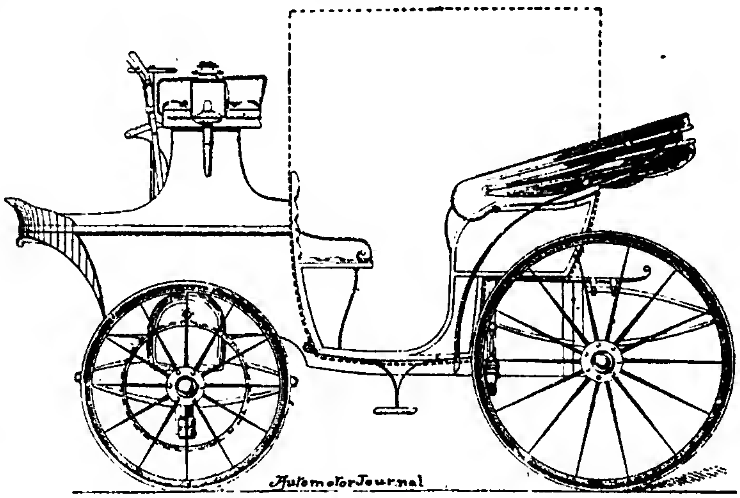

FIG. 2.

MOTOR FIRE-ENGINE.

MESSRS. MERRYWEATHER AND SONS, the well-known manufacturers of fire-engines, have naturally turned their attention to the subject of the self-propulsion of these vehicles, and have produced the accompanying design. As will be seen, the vehicle is carried on four wheels, the two front wheels being carried on a divided axle with pivoted arms, while the rear wheels are the driving wheels. The boiler is carried at the rear end of the frame, and the engine placed vertically in front of the boiler between the frames. The steam cylinders are placed above the frames and actuate the pumps, placed below the frames and directly below the cylinders, by means of rods which may be disconnected when steam is used for propulsion of the machine.

The propelling machinery consists of a crank-shaft driven by the steam cylinders operating a counter-shaft by means of gear wheels and differential gearing. The ends of the counter-shaft are provided with sprocket-wheels which drive similar wheels attached to the bearing-wheels of the machine by means of chains, one on each side of the machine. At the rear of the engine a platform for the stoker is provided and bunkers for fuel. The feed cocks and water and pressure gauges are so arranged as to be easily accessible to the stoker on the rear platform. A platform or seat is provided on the front part of the machine for the accommodation of the driver, and the steering mechanism, steam valve, and reversing gear are placed within convenient reach. The usual hose and implement box may be fitted on the top of the frames between the engine and the front seat or platform, and foot-boards for the firemen on each side. A water tank is also carried between the frames.

In the accompanying drawing A is the boiler, carried on rear end of frames, B; C are the steam cylinders actuating the pumps, D, by means of rods, E; F is the crank-shaft operating the counter-shaft, G; H is a sprocket-wheel fixed to counter-shaft; J is a sprocket-wheel fixed to the bearing-wheels, K, which are driven by the chain, L; M is the platform for the stoker; N is the platform for the driver; O is the steering mechanism; P is the handle for actuating the steam valve; Q is the reversing lever; R is the hose box; S is the water tank.

It will be observed that the design is certainly simple, but we should not like to say that it embodies the latest of our ideas in self-propelled fire-engines. Exception, for example, may well be taken to the use of chain-gearing for transmitting the necessarily rather large power necessary to run the vehicle at a good speed. Such gearing, too, would also be noisy. We doubt, too, whether the boiler and motor, presuming they are of the same type and size as are usually fitted to fire-engines built for the London County Council, could produce the necessary power for rapid movement of the vehicle.

A MOTOR FIRE-ENGINE.

The Universal Cyclometre.—Some weeks ago we received from M. Marcel Fonreau, of 54, Rue de Chabrol, Paris, a cyclometre with a request that we would test it. We have since done so, and are glad to report that within the limits to which such an instrument is applicable it is remarkably accurate. Of course, much depends upon the road and the method of driving. In the City upon asphalte the readings were correct, but on rough country roads the error was about 5 per cent. in excess. For speed testing on good roads we can recommend this instrument, but it requires to be carefully used as it is somewhat delicate and is more applicable to motor-bicycles and light vehicles than to heavy ones. It is beautifully made and very light. It can easily be attached to the handle-bar, but care has to be exercised in adjusting the endless cord which transmits the motion from the driving wheel to the counting mechanism. We would suggest a more substantial construction and attachment for ordinary motor-vehicles, while the recording tape might be dispensed with as it adds to the expense and complication, with great liability to getting out of adjustment. A clock forms part of the machine.

AN automobile race from Lille to Boulogne and back will be run on July 30th and 31st next, under the auspices of La Société Industrielle de Nord. There will also be an exhibition of motor-vehicles in Lille from July 17th to August 1st.

FOREIGN NOTES.

THE only motor-carriage in Rio de Janeiro, Brazil—a Panhard—is at present laid up for repairs, which nobody can be found to make.

THE Prefect of the Maritime Alps has issued a regulation restricting the speed of motor-vehicles to 6 miles per hour in thickly-populated districts, and to 18 miles per hour in the open country.

IN a few days' time horses will no longer be used on the Place de la République-Aubervilliers line of tramways. Five electric cars are already running. The accumulators with which the cars are supplied are, says the *Temps*, sufficiently powerful to allow of the steepest slopes being mounted at a speed of 14 or 15 kilometres an hour.

As will be seen from a letter we publish elsewhere, the Netherlands Government has consented to admit vehicles owned by members of the Automobile Club, London, free of duty, and also without any other restraint, provided satisfactory evidence of membership is forthcoming. We think the thanks of all automobilists are due to his Excellency the Minister of Finances, M. C. Van Dyck, for his liberal consideration in this matter.

IN the recent Course de Périgueux nine voitures competed in one class, six motor-tricycles in another, and three voiturettes Bollée. The total distance was 87 miles. The first arrival was M. G. Leys, on a 6 H.P. Panhard, in 3 hours 54 minutes; the next was the cyclist Osmond on a tricycle, his time was 4 hours 9 minutes. Among the Bollées the first arrival was M. Wilfred, on a 4 H.P. motor, the time being 6 hours 27 minutes. The fastest speed was thus 22·3 miles per hour.

M. PIERRE GIFFARD, a well-known French cycling journalist, is warmly advocating the use of petroleum motor-cars in Madagascar. He points out that new railways are in contemplation for early construction, and that these railways will need "feeders"; that goods will not be conveyed by horse traction for the simple reason that horses do not thrive in the beautiful but unhealthy island: and that here is the chance of the motor-car, on the roads which will have to be constructed to lead to the railways. At first he thinks that steam motor-cars, burning wood fuel, will be used, but later the more convenient oil-motors will become universal.

THE sad accidents that have lately occurred in France, at Poitiers and at Périgueux, whereby in the former case a lady was killed on the spot, and in the latter a French nobleman lost his life, not to mention the severe injuries that others received, will have the effect, it is to be hoped, of checking the rather preposterous craze for automotor racing that possesses our French neighbours. These races are no doubt invested with a certain amount of interest to those concerned, but they serve no really practical end—on the contrary they make people believe that automotors are employed more for sporting purposes than for convenience, and hence the public will come to regard motor-vehicles with prejudice and dislike. Of course accidents are possible with all machines, and as regards the one at Poitiers the occurrence was due primarily to a defective axle, but descending a gradient at fast speed was a contributing cause.

As regards the very serious accident at Périgueux, this was due to a collision between two motor-vehicles while both were going at a high speed on a raised embankment or viaduct. One vehicle was pitched over, and the other getting out of control ran down the embankment and turned over. To say that such occurrences are "accidents" is a euphemism. We rather think they are due to a lack of intelligent appreciation of the risks incurred. In other words, the drivers displayed an inexcusable foolhardiness, because it is neither safe nor necessary to drive such vehicles at these excessive speeds.

La France Automobile publishes some excellent photographs of the vehicles and of the scene of the above disaster. Both vehicles are apparently very badly damaged.

THE French Touring Club has arranged to standardise the patterns and dimensions of chains used in motor-vehicles. Both in France and Great Britain a sort of Automobile "Lloyd's" is necessary, not only in the interests of makers and users, but also in the interests of the general public. As the recent accidents show, many important fittings, such as brakes, are often very defective and inefficient.

THE Western Railway of France, which is perhaps one of the most progressive railway companies in Europe, as witness its adoption of the Heilmann locomotive (which is described in our present issue), has decided to use motor-vehicles for parcels and passengers, and has invited tenders from manufacturers.

THE Northern Railway of France is likewise progressive, and is fully alive to the advantages of motor-vehicles for certain purposes. Just as this railway was perhaps the first to employ four-cylinder compound engines long before they were known in England, so is it among the first to employ a perfect system of motor-vehicle. It has now in course of construction two separate and distinct types—the first is a single second-class compartment, with seats for 12 persons. Of this type there are two models: the one on the Serpollet system, and the other propelled by electricity (storage cells). The second type is a carriage having several compartments and a seating capacity for 50 people; it is propelled exclusively by electricity in storage cells. Both types constitute in fact a system of light railways used as feeders to the main lines. This kind of thing is apparently possible in France, but not so in Great Britain. Whether it arises from different economical conditions or from a want of enterprise on the part of our railway directors it would be hard to say.

Disfiguring the Thames Embankment.—In the March issue of THE AUTOMOTOR we discussed a proposal made by the London County Council to run a line of tramways on the Thames Embankment. We joined in efforts of others to prevent such an æsthetic outrage, and we are glad to say that on the second reading of the Bill in the House of Commons it was thrown out by a large majority. The House of Commons does not, as a general rule, impress one with a sense of profound wisdom, but in this matter it exhibited profound common sense.

Pneumatic Tyres.—Messrs. Souther have recently made a number of experiments on the friction of pneumatic tyres when inflated to different pressures. The least pressure tried was 30 lbs. per square inch, which in the medium-weight tyre tested was just sufficient to keep the felloes off the road with a weight of 180 lbs. on the saddle. Under these circumstances the efficiency of the machine was about 61 per cent. Increasing the pressure to 40 lbs. brought up the efficiency to 74 per cent., and from this onwards the efficiency augmented but slowly with increasing pressure. The highest pressure used was 70 lbs. per square inch, and the efficiency was then about 81 per cent.

Testing Feed Water.—A writer in a contemporary says:—"Treatment of feed water by an engineer has not, as a rule, met with any great success, as a number of experiences in this line that have been shown up will testify, but there are a few tests that everyone having charge of boilers should be familiar with. The presence of hard or soft water is easily detected by dropping a few drops of alcohol that has dissolved all that it can possibly hold of good soft soap. The water will turn milky white if it is hard, and remain clear if soft. Add to the water from five to ten drops of oxalate of ammonia in a test tube. If carbonate of lime be present, the water will in a short time present a clouded or milky appearance, and in a few hours a precipitate will be found at the bottom of the tube. Take some of the feed water and add a few drops of nitrate of baryta or barium chloride. If sulphate of lime or sulphuric acid is present, it will be shown by a milky appearace, and by the formation of a white precipitate. If decomposed animal matter is the cause of all the trouble, it will be shown by adding a drop of permanganate of potash, which will colour the water a bright violet rose when first added. If decomposed organic matter is present, the colour changes to a dull yellow; if present in large quantities, however, the colour will in time disappear. If, upon adding a few drops of solution of prussiate of potash a blue colour is produced directly or after some time, it shows that iron is held in solution."

CORRESPONDENCE.

**** We do not hold ourselves responsible for opinions expressed by our Correspondents.*

**** The name and address of the writer (not necessarily for publication) MUST in all cases accompany letters intended for insertion or containing queries.*

**** Correspondents are particularly requested to write on one side of the paper ONLY, to place the subject of their letters as a headline at the top of the sheet, and their names and addresses at the foot. Attention to these matters saves much time and ensures the insertion of the letter.*

THE SPORTSMAN'S EXHIBITION.

To the Editor of THE AUTOMOTOR.

SIR,—The attention of my directors having been drawn to your statement in the April number of your journal that "Under the auspices of the London Exhibitions (Limited) what was ironically termed a Sportsman's Exhibition was held for a few days recently at Earl's Court," I am desired to ask you to kindly point out in your next issue that this Company had nothing to do with the Sportsman's Exhibition beyond letting a portion of the buildings to the promoter of it. It certainly was not held "under the auspices of the London Exhibitions (Limited)," and as your statement, coupled with your following remarks, is calculated to do harm to this Company, I am sure that you only need to be acquainted with the facts in order to rectify the error into which you have unwittingly fallen.—Yours faithfully,

AUSTIN BRERETON
(Manager of the Press Department).

Earl's Court, London, *April 22nd*, 1898.

[We regret having attributed the exploitation of the Sportsman's Exhibition to the London Exhibitions Company. The error arose in consequence of a communication to us enclosing a card of invitation having the heading upon it, "The London Exhibitions (Limited)," otherwise we were guiltless of any intentional offence.—ED.]

THE VIBRATION OF MOTORS.

To the Editor of THE AUTOMOTOR.

SIR,—Can anything be done to prevent the vibration of the motor in a car? I find that ladies particularly object to this, which seems to me to be due to the lightness of the parts. I have tried springs and rubber washers placed under the holding-down bolts, but with no improvement. Makers suggest all kinds of expedients, but this means expense with no guarantee of cure. May I ask what you suggest in order to cure this objectionable feature of the motor-car?—I am, Sir, yours sincerely,

JULES LE DOUX.

Marseilles, *April 28th*, 1898.

[We refer to this elsewhere.—ED.]

THE CROWDUS STORAGE BATTERY.

To the Editor of THE AUTOMOTOR.

SIR,—Being much interested in storage cells, I shall be glad to learn the result of your criticism on the Crowdus cell which appeared in last month's AUTOMOTOR. It seemed to me that you have completely demolished the pretensions put forth by those interested in exploiting this latest American "notion." If Mr. Bowden really has a cell which is only, say, 50 per cent. lighter than British cells of the same capacity, and if his claims are substantiated by independent tests made as you suggest at the Board of Trade testing laboratory, he will be simply unable to meet the demand for such cells, and could safely order a cargo of them from Chicago. Those of us who have spent time and money in the study of the storage cell know that it is not difficult to obtain a high rate of discharge from certain chemical reactions, but other factors are cost and weight, and, perhaps more important still, life or durability, especially in traction work.—I am, Sir, yours, &c.,

PbO^2.

London, S.E.

[We have had no further communication from Mr. Bowden. In our present number we publish a most exhaustive analysis by M. Hospitalier on a Fulmen cell, which is worth serious reading to all interested in storage cells.—ED.]

PRESSURE OF AIR ON VEHICLES.

To the Editor of THE AUTOMOTOR.

SIR,—During the strong winds of last week it seemed to me that my car was sensibly retarded. With the wind in front I noticed a considerable diminution of speed, and with the wind blowing on the side I had to steer so as to counteract this tendency to go sideways. I have had a large experience in driving horse-drawn vehicles, but have never noticed that the wind made any sensible difference. Will you kindly explain why the wind should affect a motor-car and not a horse-drawn carriage, and how can I determine the pressure of the wind for any given case?—Yours faithfully,

May 3rd, 1898. A COVENTRY DRIVER.

[The wind affects a horse-drawn vehicle as well as a mechanically-propelled one; only the horse accommodates his pull to the extra resistance *automatically*, whereas the automotor, paradoxical as it may appear, does not, unless fitted with governing mechanism, which is never the case so far as our observation goes. We answer the question on wind pressure elsewhere.—ED.]

THE CONCOURS DE SPA.

Monsieur le Rédacteur de L'AUTOMOTOR.

MONSIEUR,—Nous vous prions d'insérer dans votre estimable journal l'information suivante :—

La liste des prix spéciaux pour la fameuse course des automobiles Bruxelles-Spa, qu'organise les 25 et 26 juin prochains, l'Automobile Club de Belgique s'accroît tous les jours; aux prix offerts par Sir David Salomons, le Touring Club Belge, il faut en effet ajouter le prix du Comte de Hemricourt de Grunne, membre du Comité, qui tient à récompenser non pas la voiture la plus rapide, mais celle qui présentera le plus de qualités au point de vue *pratique*.

Une cinquantaine de membres nouveaux ont éte admis dans le courant de ce mois aux ballotages de l'Automobile Club, parmi eux MM. Lucien Vorlet, à Verviers; Henry De Clercq, à Bruxelles; Ernest Preudhomme, à Bruxelles; Philippe de Burlet, à Bruxelles; Raoul Gcelhand de la Bistrate, à Anvers; Camille Jenatzy, à Bruxelles; Comte Jules de Monceau, à Bruxelles; Baron de Dieudonné de Corbeekooer Loo, à Louvain; Fernand Hérard, à Paris; Baron Lundeu; Gérard Nothomb, Albert Mans, Albert Liérart, Albert Tesch, à Bruxelles; MM. Armand Dresse, Edmond Dresse, Dawaut Preudhomme, Dawaut Adrien, Dawaut, Georges fils, Maurice Leloux, Georges Béar, Auguste Aerts, Charles Rocour, G. Rocour, Jules Lamarche, Alfred Lamarche, Max Hauzeur, Adolphe Hauzeur, Dieudonné Sklin, Fernand Pisard, Georges Deprez, Auguste Gillard, Auguste Dumoulin, Chevalier Octave de Mélotte, P. Van Hougaerden, Gustave Terwaugne-Dalloge, Mathieu Douvoiseri, de l'Automobile Club Liégeois.

Max Coget, Joë May, Léon Génart, Felix Pardon, Paul Gecscher, de Timary; Lucien Niguet, de Bruxelles.

L'Automobile Club Liégeois vient d'être reconnu par l'Automobile Club de Belgique comme "Cercle Adhésif" et a par conséquent le droit de désigner un de ses membres pour le représenter au Conseil d'administration de l'Automobile Club.

Veuillez agréer, Monsieur le Rédacteur, avec mes remerciements l'expression de mes sentiments distinguées.

Comte FERNAND DE VILLEGAS DE ST. PIERRE,
Le Secrétaire Général.

Automobile Club de Belgique,
14, Place Royale, Bruxelles.

WHEEL GUARDS.

To the Editor of THE AUTOMOTOR.

SIR,—I hope you will allow me space in your journal to suggest a plan for minimising street accidents from motor-cars or other vehicles. I say motor-cars particularly because this is a modern vehicle, and one that will, I believe, be very much used in another 10 years or less. My plan is to box the lower half of the wheels in to within, say, a couple of inches of the ground, so that if they struck an object on the ground it must push it away and not run over it. I enclose rough sketch for your perusal.—Yours obediently,

"PROTECTOR."

[We do not reproduce our correspondent's sketch as his meaning is sufficiently plain, and we see no practical difficulty in adopting such a plan, or a modification thereof. Something similar is already in use in the Paris tramcars.—ED.]

PETROL STORES.

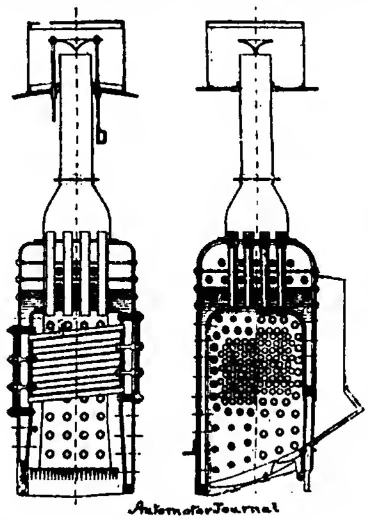
To the Editor of THE AUTOMOTOR.

SIR,—Under heading as above I see you give my name and address. Permit me to say I do not keep a store for sale of petrol; but as I generally have a few gallons by me, I shall be happy to help any brother automobilist who may not have sufficient to reach either Farnham or Guildford.—Yours, &c.,

Barfield, Farnham, *April 18th*, 1898. JOHN HENRY KNIGHT.

THE WEIDKNECHT BOILER.

AMONG the many types of boiler now being used for steam motor purposes it is interesting to note that in France the vertical boiler in one or the other of its modifications finds special favour. With us there is a strong leaning to water-tubers, but so far our French friends have not followed us in this respect. De Dion et Bouton have been very successful with their pot boiler, while Le Blant has been no less successful with his modified "Field." M. Wiedknecht employs a type of vertical boiler which we herewith illustrate. As will be seen, it contains some features which we are not accustomed to see associated in these boilers, and which many authorities will hardly



call good practice. However, M. Wiedknecht has to satisfy the very rigorous French authorities, and so far, we understand, he has found this boiler very well adapted to his steam vehicle. This boiler has a grate area of 3 square feet. There are 87 tubes 1·18 inches diameter external; the total heating surface being 64 square feet. The boiler will evaporate 572 lbs. of water per hour. It supplies steam to a motor which has two cylinders, 4·92 inches diameter by 4·92 inches stroke. Steam is cut off at from 10 per cent. to 83 per cent. of the stroke by a variable valve gear of the Soling type. At 350 R.P.M. the H.P. is 20. The consumpt is 10·7 lbs. of coke per mile on good roads, and about 7 gallons of water; the weight of the vehicle fully loaded with 16 passengers and about half a ton of baggage being nearly 7 tons, and the maximum speed on a good level road being 9 miles per hour.

THE Peugeot Motor Company has just increased its capital from 800,000 francs to 2,400,000 francs. The subscriptions were raised among the shareholders without any difficulty.

SAYS an American Exchange, James N. Wood, of Wood, Meagher, and Company, Richmond, Va., has nearly completed a single cycle gasolene engine which develops 1 H.P. and weighs only 50 lbs. He is also engaged on an Otto cycle marine-motor which will be reversible like a steam-engine. He expects to be able to build single cycle vehicle motors as light as 20 lbs. to the H.P. One often hears of these much needed inventions, but somehow they do not eventuate.

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL" by HERBERT HADDAN and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

Specifications Published.

THE following is a List of Specifications recently published, and obtainable at the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform charge of 8*d.* per copy. Owing to the enormous pressure upon our columns it has been found impossible to deal in any other form with the accumulation of patents now being taken out in connection with automobilism. As far as possible, a selection for special mention is made by the Editor from the more prominent inventions:—

Applied for during 1896.

29,610. W. J. H. JONES, 21, New King Street, Deptford, London. Motors adapted to petroleum vapour or gas.

25,221. V. E. PRETOT, 21, Boulevard Poissonniere, Paris. Motor road vehicles.

1897.

659. L. RUB, 93, Schille Street, Augsburg, Germany. Igniting devices.

878. L. PHILIPPOT, 34, Rue du Parc, Ivry (Seine), France. Atomising device.

1,073. L. SHERRIN and F. SHERRIN, Gate House, Ingatestone, Essex. Hydraulic motor.

1,475. H. PORON, Troyes, Aube, France. Engines and gear.

1,694. A. WINTON, 37, Bolton Place, Cleveland, Ohio, U.S.A. Explosion engines.

1,695. A. WINTON, 37, Bolton Place, Cleveland, Ohio, U.S.A. Explosion engines.

1,707. F. PARKER, 2, Wyndham Street, Brighton. Motor-cars.

2,924. C. T. CROWDEN and W. L. P. WEBB, Vernon Lodge, Leamington. Variable speed gear.

4,785. H. W. METCALFE, 36, Balls Road, Claughton, Birkenhead. Friction clutches.

4,963. C. A. HAMILTON, 12, Artillery Street, Londonderry. Steam, gas, and air engines.

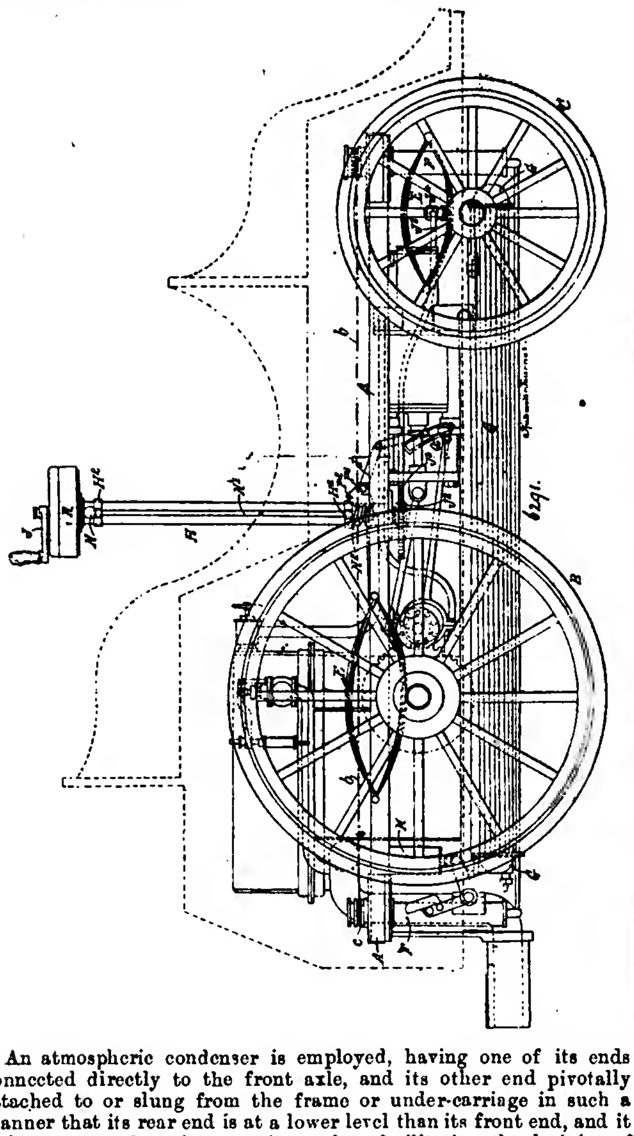
21,459. R. P. PICTET, 37, Rue Jean Goujon, Paris. Air and steam motors.

22,578. R. F. MOORE, 78, Bensham Manor Road, Thornton Heath, Surrey. Speed alarm.

28,493. C. DIETRICH, 245, Bauhofstrasse, Elsterwerda, Germany. Means for lubricating bearings.

6,291. Self-Propelled Vehicles. Edward Smith Higgins, 127, Brixton Hill, Brixton; Herbert Alfred Bessemer, 42, Therapia Road, Honor Oak; and William Bourchier Nicholson, Acacia Cottage, Acre Lane, Brixton, all in the County of Surrey. March 10th, 1897.

Relates to a motor-car or self propelled vehicle, in which the motor machinery is supported by a framework or under-carriage resting upon the axles independently of the body of the vehicle, which is supported through the medium of suitable springs upon the said framework or under-carriage, or upon the axles, and adapted to be raised to permit access to the said machinery for cleaning or repairs. The upper and lower parts of the springs can be readily disconnected or disengaged, and screw jacks, hydraulic jacks, or the like are used for raising the carriage-body relatively to the said machinery.

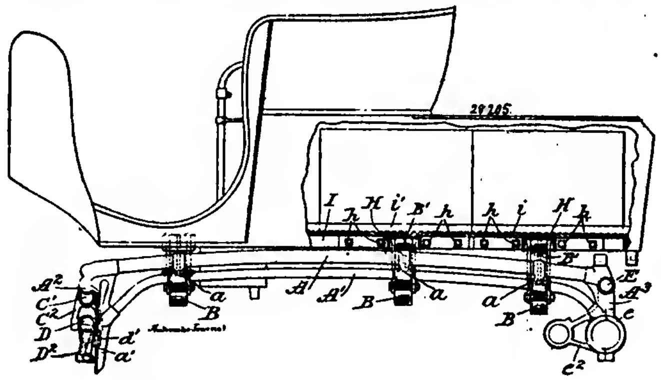


An atmospheric condenser is employed, having one of its ends connected directly to the front axle, and its other end pivotally attached to or slung from the frame or under-carriage in such a manner that its rear end is at a lower level than its front end, and it is free to turn about its rear pivots, thus facilitating the draining of the said condenser, and providing for an increased circulation of air around the condenser-tubes.

The mounting of the various steering, controlling, and other operating or indicating devices is within or upon an upright or standard supported upon the axles independently of the carriage-body. The propelling machinery is contained in a space enclosed by the said carriage-body and the condenser.

28,205. Running Gear and Frames of Motor Road-Vehicles, &c. Hiram Percy Maxim, 1, Columbia Street, Hartford, Connecticut. Date claimed, May 3rd, 1897. Date of application, November 30th, 1897.

The invention chiefly relates to the running gear. The side members of the running gear frame are composed of two rods or bars, A and A^1, one above the other, firmly united at or near their ends to the front and rear end members, and to each other, by suitable union pieces, A^2 and A^3. The two rods or bars may also be united at intervals between their ends by clips, *a a*, which also serve



as means of attachment for the springs, B B. These two rods or bars form a girder which gives the required strength without excessive weight. Both rods or bars, A and A^1, may be curved or arched upwardly, the lower rod or bar, A^1, having considerable curvature near its ends to bring it into substantial parallelism with the upper rod or bar, A, for the greater portion of its length. The end portions thus act as braces to most rigidly support the front crab-jaw and rear-driving shaft bearing respectively against horizontal strain. The front end member of the running gear is also composed preferably of two rods or bars, C^1, one above the other, firmly connected to the side members and to each other at or near their ends by means of the union pieces, A^2, referred to. The front member is preferably arched or curved downwardly, inasmuch as it is supported by the front axle at its middle, and therefore is better calculated to withstand the strain upon it, while the side members, which are supported at their ends and in turn support the weight of the body between their ends, are better calculated to stand the strain upon them by being arched or curved upwardly. The double construction of each side member and front end member imparts greater rigidity and strength to the frame. The front end member is provided at its middle portion with a bracket or fork, C^2, to which is pivoted, on a horizontal pivot, the front axle. The latter is preferably composed of a tubular rod or bar, D, which is curved or arched upwardly, and a tie-rod, D^1, the said rods, D and D^1, being united at their ends by suitable union pieces, D^2, which also form the forks for the support of the front wheels. The union pieces, A^2, are provided with crab-jaws or extensions, a^1, which stand in rear of the front axle and afford vertical bearing surfaces for the same. Each union piece, D^2, or each end of the front axle is provided with a clip, d^1, secured thereto, which is extended around and behind the edge of the adjacent crab-jaw to prevent the front axle from being torn away from its bearing against the crab-jaw when backing up, &c.

The rear member of the running gear frame may be a substantially straight bar, E, preferably tubular, which is rigidly secured to the union pieces, A^3, and is provided with depending brackets, *e e*, for the support of the rear shaft or axle, F, and the motor and intermediate mechanism.

The springs, B B, which may be of usual or suitable character, and are preferably disposed transversely, having their ends secured to the side members of the running gear frame, support the body of the vehicle.

The invention also relates to the construction and suspension of the motor, and the driving connections thence to the driving shaft of the vehicle, and to novel means for securing the driving wheels to the driving shaft.

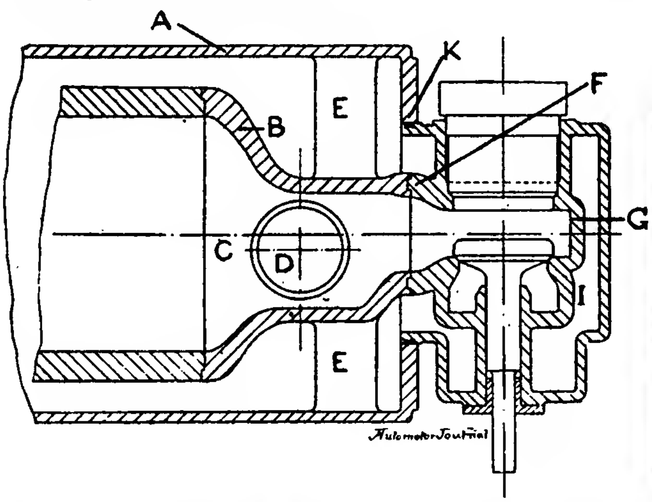
8,318. Oil-Engines. Charles William Pinkney, 77, Raglan Road, Smethwick, Stafford. March 31st, 1897.

The combustion chamber is provided with a surrounding water-jacket, which may be a continuation of a water-jacket surrounding the cylinder in which the piston works. The oil and air inlets are arranged so that the oil and air enter the combustion chamber before they enter the vaporiser, which may be in communication with the rear end of the combustion chamber, the igniting arrangement being in communication with the vaporiser.

When the piston makes its charging, or forward, stroke, the oil and air are drawn into the combustion chamber and cylinder, and, at or about the end of the charging stroke, all the valves are closed, and, at the back, or compression, stroke of the piston, the oil and air are forced into the combustion chamber and compressed therein, a portion entering the vaporiser, which is highly heated by a petroleum lamp, or any other suitable heating device. The portion thus entering the vaporiser becomes thoroughly gasified, whilst the portion in the combustion chamber, being cooler, is in a less gasified condition. When the piston has reached about the end of its compression stroke the portion of the charge of oil and air which is in the vaporiser is ignited, which ignition may be effected by any suitable means, such as an ignition tube, or an electric spark. The portion so ignited fires back into the portion of the charge in the combustion chamber and completes the gasification of the charge, and it explodes, or ignites, at a lesser rate than it would do if the charge in the combustion chamber had in the first instance been more highly heated and more perfectly gasified, and thus injurious shocks are prevented, whilst heavy oils may be employed without the use of the large vaporisers which would be necessary if the whole charge were thoroughly gasified at once.

3,370. Internal Combustion Motors. Francis William Crossley, of Crossley Brothers (Limited), Openshaw, Manchester. February 9th, 1897.

This invention relates more particularly to internal combustion motors of considerable size, and has mainly for its object the construction of the breech or closed end of the cylinder, so as to allow of greater freedom for unequal expansions, thus reducing strains which might otherwise be excessive.



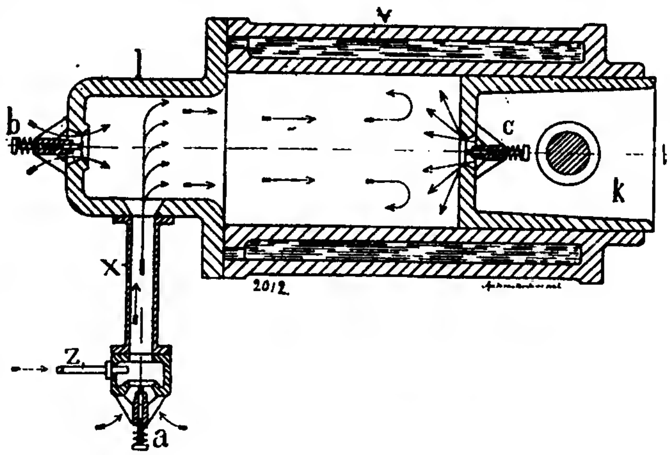
The figure shows a sectional elevation of the end of an "Otto" type gas-engine cylinder. The breech end of the cylinder mainly consists of an outer shell, A, and an inner shell, B, the space between these two shells forming a portion of the water jacket. The space, C, inside the inner shell is the major portion of the "compression" space. The inner shell, B, is attached to the outer shell, A, by a branch connection, D, through which the charges of air and gas enter, by means of any other desired connections, and by means of ribs, E, suitably disposed. These connections and ribs are placed as close to the cylinder end as may be convenient.

The outer end of the inner shell, B, is coned or otherwise reduced to a smaller facing, F, to which the exhaust valve casing, G, is bolted by means of bolts, which pass from the inner shell, B, close to the latter joint, F, to the outside of the exhaust valve casing, G.

The exhaust valve casing, G, is made with a water space, I, which is placed in free communication with the water space of the breech piece all round the joint, F, of the exhaust valve casing, G, the outer metal of the valve casing, G, terminating at the cylinder side in a circular path, K, which fits sidewise in a bored hole in the internal flange of the outer shell, A, of the breech piece, a water joint being made there by means of a ring of indiarubber in a recess in the circular path, K, or by any other well known means.

2,012. Production of the Explosive Mixture in Oil-Engines. Emil Capitaine, Frankfurt on the Main, Germany. January 25th, 1898.

In the drawing, *v* is the cylinder, *k* the piston, *l* the explosion chamber, *x* the vaporiser for the oil, which tube is heated outside by a flame and inside by the heat generated by the explosions; *a*, *b*, and *c* are the three air-admitting valves, *z* is the pipe which supplies the oil.



During the suction period the oil admitted or drawn through pipe, *z*, is driven into vaporiser, *x*, by the action of the air which enters through valve *a*. From the vaporiser, *x*, it passes into the explosion chamber, *l*, and thence into cylinder, *v*. The oil is vaporised in the vaporiser, *x*, and this oil vapour is forced into the combustion chamber by the air which enters at *a*. As at the same time air is admitted through valve *b*, the mixture of air and vapour issuing from vaporiser, *x*, will be driven with increased velocity into the cylinder space.

As the mixture of oil vapour which issues from the vaporiser mixes little or not at all with the air which is admitted through valve *b*, the said mixture is surrounded by the air passing or drawn in through the latter valve, whereby the oil vapour is prevented from coming into intimate contact with the walls of the explosion chamber and cylinder and thus condensing thereon.

Valve *c* in the piston allows air to flow through the still incomplete mixture of oil vapour and air, so as to render the mixture more perfect. It is thus possible to effect a more or less intimate mixture just before the end of the suction period or during the whole or a part of its duration. This valve can be actuated by known devices in such a manner that it is in operation during the full time of the suction period or more or less towards the end thereof. Furthermore, the air that is admitted through valve *c* may be allowed to flow into the cylinder in an annular-shaped spray or stream, or in a greater or less number of fine streams.

7,972. Instantaneous Steam Generators. Ells Dagnall, 30, Maude Grove, Fulham, S.W., and Alfred William Southey, 16, Elm Street, Gray's Inn Road, W.C. March 27th, 1897.

The generator consists of a set of straight steel tubes of circular section, each comprising an outer tube, *a*, and inner tube, *b*, of such diameter as to leave an intervening annular space, c. The tube, *b*, communicates at one end with the space, c, and the tubes are so connected in series that the water, or water and steam, shall circulate through them in succession, entering each through the inner tube, and returning through the annular space, and so on through the whole of the tubes connected in series. The connections are formed at the one end by a casting or header, d, into which the tubes are screwed, so that at this end there is no communication between them but a passage, e, through the casting or header, by which the annular space, c, of the one tube connects with the inner tube, b, of the next in the row, the superposed rows of tubes being also connected in series by the annular space of the last of the lowermost row being similarly connected to the inner tube of the first of the row above, and so on, the last of the upper row being connected to a steam drum, f. At the opposite end the inner tube is merely made shorter than the outer tube, and its end left open, the end of the outer tube being closed by a plug, g. The inner tube, b, is fitted with a sleeve, h, corrugated helically so as to fit between the two tubes, and acting as a baffle to cause the steam and water to follow a helical course through the annular space, and so cause a scouring action on the

FIG. 1. FIG. 4.

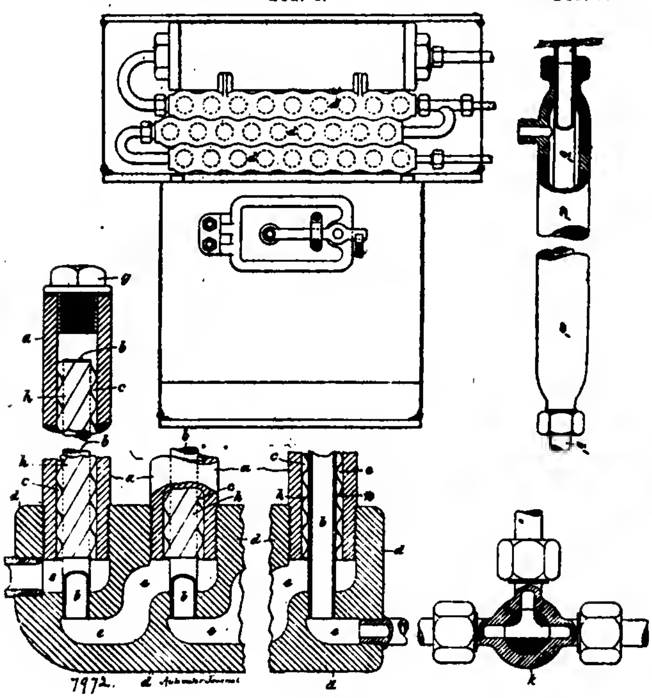


FIG. 3.

sides of the outer tube, whereby saline deposits in the outer tube will be prevented. Or the water and steam may be allowed to circulate through the inner tube only, as shown in Fig. 4, especially in the case of the tubes nearest the fire; the water hermetically held between the inner tube, b^1, and the outer tube, a^1, preventing the outer tube being burnt either by the action of a badly-regulated fire or during stoppages. The heat applied to the outer tubes will be rapidly transmitted through them to the water contained in the inner tubes through the agency of the water contained in the outer tubes.

The water is supplied by a feed-pump worked by the engine, and capable of being also worked by hand at starting, and is fed to the inner tube of the first of the lowermost row, and also to, say, the first tube of the uppermost or any intermediate row, the feed being under the control of a three-way cock, k, by which the proportional quantities of water entering at the two points, and consequently the proportional quantities of the two classes of steam, may be regulated, the water supplied at the second point escaping the action of the hottest portion of the generator, and consequently generating saturated steam, which mixes with the superheated steam coming from the lower rows of tubes, the result being a mixture of saturated and superheated steam, which may be used without injury to the engine. The regulation of the water feed may be automatically effected by means of a device controlled by a pyrometer.

PETROL STORES, REPAIRERS, AND STORAGE OF MOTOR-VEHICLES.

THE following list comprises the information already given in our last issue and in THE AUTOMOTOR POCKET-BOOK, with additional particulars in the compilation of which we have been greatly assisted by the Secretary of the Automobile Club of Great Britain.

It must be understood that we do not vouch for the complete accuracy of the information or the competency of the repairing firms mentioned, but it is hoped that our readers will assist in the composition of a complete and reliable list by sending us, from time to time, corrections in and additions to the matter following:—

References. — (*a*) Petrol. (*b*) Repairs. (*c*) Accommodation for storing motor-vehicles. (*i*) Ironmonger. (*o*) Oil merchant. (*) Authorised agents of Messrs. Carless, Capel, and Leonard.

VOL. II. No. 21. JUNE 15TH, 1898. PRICE SIXPENCE.

CONTENTS.

THE LIVERPOOL TRIALS OF HEAVY MOTOR-VEHICLES.

THESE trials, which have been looked forward to with such anticipation by traders, engineers, and others interested in locomotion in all parts of the country, were duly commenced in Liverpool on May 24th and were terminated on the morning of May 28th. The preparations for their conduct had been made on a most elaborate and extensive scale, and all the arrangements were carried through without a hitch. The trials were, in fact, from almost every point of view a distinct success, and they mark a new era in automobilism because they have demonstrated the practicability of moving weights up to 5 tons at good commercial speeds on vehicles which weigh less than 3 tons. Although many, including ourselves, never had any doubt about the feasibility of doing this, yet generally speaking, and especially as regards Liverpool, the impression largely prevailed, even among shipowners and engineers, that it could not be done.

As every one interested is aware, these trials were inaugurated by the Self-Propelled Traffic Association, and were carried out under the auspices of the Liverpool branch, because it is in Liverpool and the surrounding district that the problem of the cheap transport of heavy goods is of such vital importance. The special object of the trials was to arrive at a type of vehicle which could not only replace horse-drawn vehicles but also compete with the railways as regards cost of transport, &c. In pursuance of this object the following conditions were laid down by the Association :—

I.—The vehicles shall be self-propelled. The part carrying the generator, or motor, or both, may be articulated and detachable, but the propulsion shall be effected by utilising the load for adhesion.

II.—The vehicle shall be propelled by mechanical power alone, but (with the reservation that the judges may disqualify and prohibit from competition any vehicle or motor which, in their opinion, is faultily constructed or dangerous from any cause whatever) there shall be no restriction on the source of such power or the nature of the agents used.

III.—The vehicle shall be capable of going anywhere that a horse-drawn vehicle carrying the same load can go, and of being placed in the same positions, and withdrawn therefrom, without external assistance.

IV.—The vehicle shall be capable of working into and out of an embayment of one and a half times its own length.

V.—The vehicle shall conform in all respects to the requirements of the Locomotives on Highways Act, 1896, and, in the case of its being oil-propelled, of the "Regulations as to Petroleum" issued by the Home Secretary under Section 5 of this Act.

VI.—All working parts shall be properly encased.

VII.—The tare of the vehicle shall be recorded both inclusive and exclusive of any water, fuel, or accumulators used for the purpose of propulsion.

Competing vehicles were to be classified as follows :—

Class I.—Vehicles capable of carrying a minimum load of 2 tons of goods. Vehicles entered in this class may be open or covered.

Class II.—Vehicles capable of carrying a minimum load of 5 tons of goods. Vehicles entered in this class shall have level platforms only without any covers.

To these classes the following regulations applied :—

I.—The average speed during the trial runs, inclusive of stoppages, shall reach : (*a*) in Class I, six miles per hour; (*b*) in Class II, four miles per hour.

II.—The vehicle shall have a level platform area of not less than : (*a*) in Class I, 60 square feet; (*b*) in Class II, 110 square feet.

III.—In Class II the height of the floor line from the ground shall be not less than 3 feet 9 inches, and shall not exceed 4 feet 3 inches.

Objection was taken to this classification as the limit of 2 tons as a minimum would effectually prevent the makers of oil-propelled vehicles from competing, while the higher minimum weight of 5 tons in Class II, coupled with the minimum speed of four miles per hour, was felt as being too onerous. In order to meet this latter objection the Association decided to have a third class to which the only regulation applying was "that the vehicle should carry a minimum load of 2 tons."

In arriving at a judgment of the merits of any vehicle to fulfil these conditions the judges were to more particularly regard the following points:—

(*a*) *Cost.*—Economy of working, including attendants.

(*b*) *Control.*—Stopping, starting, changing speed, steering, and reversing, particularly under adverse conditions, such as on inclines, or in confined spaces.

(*c*) *Working.*—Noise, smell, visible vapour, dust, or other nuisance when travelling. Number of mechanical operations requiring attention from the driver. Efficiency of brakes. Time occupied in preparing the vehicle for service on the road. Ability to start from rest on an incline of 1 in 16. Speed—within legal limits. Distance run without taking or receiving supplies of fuel, oil, gas, electrical or chemical materials, or electrical current, water, or of any agent employed for actuating the motor or assisting its working. Ability to complete the course without stopping to effect repairs, adjust parts, apply lubricants, or for any other purpose or cause not provided for in the itinerary. Freedom from a breakdown of any nature.

(*d*) *Construction.*—Strength of frame and working parts. Quality of workmanship. Efficiency of springs. Freedom from complicated or over-refined parts. Facility with which repairs can be effected. Capacity of bunkers, oil and water tanks. Ratio of available to total platform area—preference will be given, as regards vehicles entered in Class II, to a system that gives the entire platform, from end to end, free for goods. Ratio of tare to power of motor. Ratio of tare to weight of freight carried during the trials.

For steam-propelled vehicles attention was to be given to:—Action of feed-pumps or injector; ample supply of steam; consumption of fuel and water per mile; leakage of steam or water; and arrangements for stoking.

Regulations were also made for oil-propelled vehicles, but inasmuch as none of these were entered it is unnecessary to specify them. Intending competitors engaged to abide by the following rules:—

I.—The vehicle shall carry at least the minimum weight of goods, or any weight in excess declared by the competitor, throughout the continuance of the trials. Suitable ballast will be provided by the Association.

II.—Each competitor shall himself make all arrangements for the necessary staff and appliances to work his vehicle or vehicles. Accommodation for the vehicles, in Liverpool, will be provided by the Association. Vehicles intended for trial shall be registered as "arrived," at this depôt, not later than 3 p.m. on Monday, May 23rd, 1898.

III.—An official observer will accompany each vehicle during the trial runs, to take notes of behaviour, fuel, and water consumption, &c., and no repairs will be permitted without his knowledge and consent.

IV.—Any vehicle withdrawn from competition during the trials, except under the written authority of the judges, shall not be eligible for a prize, or for commendation.

V.—Six photographs of each vehicle, together with one perfect negative, shall be furnished by the competitor, not later than May 16th, 1893. These must be delivered in good order at the Liverpool Royal Institution, addressed to the Hon. Sec., Self-Propelled Traffic Association.

VI.—Full drawings of any vehicle shall be submitted to the judges in confidence, if required by them, prior to the final adjudication.

VII.—Entries shall be made on printed forms (to be obtained from the hon. sec.) at any time prior to 12 noon on the last day of March, 1898, and shall be accompanied by an entrance fee as under:—

	£	s.	d.
For one vehicle	£5	5	0
For each additional vehicle by the same competitor	1	1	0

Entries shall be addressed, under cover of a registered letter, to the Hon. Sec., Self-Propelled Traffic Association, The Royal Institution, Colquitt Street, Liverpool.

VIII.—A complete list of particulars shall be lodged with the hon. sec. not later than May 16th, 1898. The description must be type-written, or printed, and six copies must be furnished. The tare weight of the vehicle, both exclusive of any water or fuel, and in complete running order, must be given, also, as briefly as possible, any peculiarities of construction or of working to which the competitor desires to draw the attention of the judges.

IX.—Each competitor shall arrange to have his vehicle or vehicles ready for inspection by the judges at 9 a.m. on the morning of Tuesday, May 24th, 1898, in the depôt that shall be used as headquarters during the trials.

X.—All vehicles shall be stored over-night at the depôt or depôts provided by the Association.

XI.—Lots will be drawn to determine the order of starting. It is intended to begin the runs shortly after 9 a.m. on each of the four days, the vehicles following one another at intervals of about ten minutes.

XII.—At the conclusion of the trials, any vehicle, or motor, or part thereof, shall be opened up, in confidence, for inspection by the judges, if required.

The judges reserve to themselves the right of absolutely disqualifying any competitor for any infraction of these rules.

While obeying in all respects the instructions of the judges, and the conditions of the competition generally, it is to be fully understood and agreed by every competitor that no responsibility, legal or otherwise, is to attach either to the judges or to the Self-Propelled Traffic Association, in respect of anything, or for any damage or injury caused to any person or thing, but that all responsibility of every sort and kind, whether pecuniary or otherwise, is to attach to the competitor, and is to be borne by him.

The following were the instructions issued to the official observers:—

Duties of Official Observers in Charge of Vehicles during the Runs.

(*a*) To be in attendance at the Prince's Dock depôt on the four mornings, May 24th to 27th inclusive, at or before the times named below.

(*b*) To "take charge" of the vehicles in the following rotation:—

	a.m.	a.m.			Declared working pressure.
May 24th.	Attend ;	Start ;	No.	on Route A.	lbs.
25th.	,, ;	,, ;	,,	on ,, A.	,,
26th.	,, ;	,, ;	,,	on ,, B.	,,
27th.	,, ;	,, ;	,,	on ,, B.	,,

To "take charge" means to receive custody from the official observers in charge of the depôt before the heating of the boiler is allowed to be started.

(*c*) To observe and to record the time occupied in raising steam from "all cold" to the declared working pressure. To note the consumption of fuel for this purpose. Small weighing machines are provided.

(*d*) Where the boiler is fired with coke or coal, to allow no stoking to be done from the weighed supply on the vehicle until after the start.

(*e*) Fifteen minutes before the official starting time, to have the vehicle loaded with its full complement of fuel, water, and passengers. To record the number of bags of ballast, which must be examined before each run. Each person carried must show the ticket giving his exact weight. A weighing machine with attendant is provided. Passengers must be informed that they will be required to complete the entire journey.

(*f*) Five minutes before the official starting time, to have the vehicle brought to the starting point. At the moment of starting, *i.e.*, when at the starting point and waiting for the starting signal, steam must be raised, and all firing up to departure done, by the use of another lot of fuel.

(1) To see that the attendants completely fill the tanks (oil and water).
(2) To measure the position of the water level in the boiler.
(3) Where the boiler is fired with coke or coal, to note and to call the attention of the judges to the state of the fire.
(4) To have the two measuring cans on board.

(*g*) At the word of the judges to "start," to note the time and the boiler pressure.

(*h*) To keep the "log" of the run and to observe the general behaviour of the vehicle upon the road. The items included under "General Behaviour" are enumerated on the second page of the log-sheet. Particular attention is to be given to the stopping and starting on the hills, *i.e.*, to note how promptly the vehicle is brought to rest after the word "stop" (to be given opposite the placard), and whether it is necessary to back before starting again. Each "stop" is to be for 15 seconds, at the expiration of which the word "start" shall be given. The control of the feed-water is also an important point; when ascending hills, observe fluctuations of water in the gauge-glass as an indication of possible priming. Note whether the frame shows signs of stress, also degree of lurching and vibration.

(*i*) Intermediate depôts, to regulate the stoppages, where possible, to occupy 15 minutes precisely. Every vehicle must stop for not less than 15 minutes, whether supplies are required or not. To check the supplies of water and fuel. All water and oil must be measured in the stamped cans. To despatch telegrams to headquarters on the forms supplied.

(*k*) To record the arrival at the Prince's Dock depôt so soon as at the entrance gate. To note the boiler pressure at this moment and the level of the water in the boiler. Where the boiler is fired with coke or coal, to note and to call the attention of the judges to the state of the fire.

(*l*) To check the weighing of the coke or coal unused. To check the measuring of the water and oil required to fill the tanks.

(*m*) To transfer the vehicle to the custody of the official observers in charge of the depôt, who will sign the "log" in the spaces provided.

(*n*) To hand the completed "log" to the honorary organising secretary (Mr. E. Shrapnell Smith), or to his acting representative in the office at the Prince's Dock depôt.

By order of the judges,
E. Shrapnell Smith, *Hon. Sec.*

In addition to these travelling observers, another set of official observers were placed in the charge of the depôt at the docks, whose duties are set forth below :—

Duties of the Official Observers in Charge of the Depôt.

To enforce the following regulations :—

(*a*) All repairs shall be made in the presence of, or with the full cognisance of, the official observers in charge.

(*b*) No vehicle shall be repaired or otherwise handled by any person, except between the hours of 8 a.m. and the time of departure, or during a period of two hours after returning, unless by the written permission of the judges.

To perform the following duties :—

(*a*) To attend the depôt at 8 a.m.

(*b*) To record the nature and extent of any repairs effected in the depôt.

(*c*) To deliver vehicles into the custody of the official observers appointed for the runs.

(*d*) In the absence of both the official observers appointed to any vehicle, to record—

(1) The time at which the heating of the boiler is started and the time at which the declared working pressure is obtained.
(2) The consumption of fuel for this purpose.

Meantime to secure substitutes.

(*e*) To "post" the telegrams received from the various depôts *en route*.

(*f*) To accept the custody of each vehicle, when the official observers in charge have completed the fuel and water measurements.

(*g*) To record the time of delivery by the road observers, and the time at which the attendants finally leave the vehicle.

A form having the necessary spaces is attached.

By order of the judges,
E. Shrapnell Smith, *Hon. Sec.*

The observers attached to the various vehicles had to fill up a log sheet, a specimen copy of which we append :—

Originally 10 vehicles were entered for the competition: four in Class I, one in Class II, and five in Class III. Ultimately these numbers were reduced, and at the trials the competing vehicles were :—

Class I.—*Minimum load,* 2 *tons; minimum average speed,* 6 *miles per hour; minimum platform area,* 60 *square feet.*

No. 1. "Lifu" lorry; Liquid Fuel Engineering Company, 20, Abchurch Lane, London.

No. 4. Lorry; the Steam Carriage and Wagon Company, of Chiswick, London.

Class II.—*Minimum load,* 5 *tons; minimum average speed,* 4 *miles per hour; minimum platform area,* 110 *square feet; platform to be not more than* 4 *feet* 3 *inches, nor less than* 3 *feet* 9 *inches, high.*

No. 3. A six-wheeled articulated lorry; the Steam Carriage and Wagon Company, of Chiswick, London.

Another lorry, No. 5, carrying over 5 tons, and also propelled by steam, was entered by the Lancashire Steam Motor Company, of Leyland, and was known officially as No. 5, but as it carried more than 2 tons it could not enter Class I, and as it carried less than 5 tons it could not enter Class II. This vehicle carried 4 tons.

It will thus be seen that the programme was sufficiently rigid, the classification adopted restricting the competition entirely to vehicles carrying heavy loads, and therefore necessarily propelled by steam. Whether it would have been advantageous to have extended the classification so as to embrace light goods' vans is a matter upon which opinions may differ. Considering the elaborate and extensive preparations made and the few entries in the heavy classes, it would have been well to have made the trials more comprehensive and more catholic in their scope. On the other hand, this was not the object for which they were being conducted, and inasmuch as the funds came mainly from those interested in heavy traffic, it was only natural that the latter subject should monopolise the attention. It will be observed that Continental manufacturers are conspicuous by their absence. This is due to the fact that the types of vehicles intended for heavy traffic in France, as exemplified by the Scotte No. 2 and the De Dion et Bouton No. 14*, weigh each considerably over 4 tons, which, being in excess of the weight allowed by the British law, renders any competition on their part futile. Indeed, these Liverpool trials could possess but little interest for French manufacturers; whereas, had the classification included light goods' vehicles, it would have been worth the while of our French friends to have entered the competition, as many of the French light vehicles possess several points which deserve to be known to British buyers.

The prizes offered were £100, £75, and £50. Considering the preparation necessary and the time occupied in the trials, it cannot be said that these prizes are of a very valuable nature, or that they would recoup their winners, or that they are altogether worthy of a city such as Liverpool, which has so much to gain from automobilism. The municipality which spends the ratepayers' money on organs and novels cannot seemingly find it consistent with municipal virtue to encourage automobilism, and so Liverpool is yet without an automotor dust-cart.

The judges appointed to conduct the trials were Sir David Salomons, Bart, P.S.P.T.A., Professor Boverton Redwood, F.I.C., &c., Professor Hele-Shaw, M.I.C.E., &c., E. R. Calthrop, Esq., M.I.C.E., S. B. Cottrell, Esq., M.I.C.E., and H. West, Esq., M.I.N.A. These gentlemen were assisted by a large staff of assistants, who were stationed at the depôt, and who recorded the weights of the vehicles, the quantity of fuel, water, and ballast put on board, and, in general, examined, measured, and noted the physical condition of each vehicle with a minuteness which comes of that teaching which says Science is Measurement. Every passenger who was carried was also duly weighed, and to each vehicle was appointed two official observers. These were young students from the Engineering Classes at the Victoria University, at which Professor Hele-Shaw occupies the Chair of Engineering.

The following is a complete list of the official observers:—J. Reginald Taylor, H. N. Giles, J. H. Lowery, Norman C. Lange, A. R. Ellison, E. A. Rosenheim, William Bayliss, L. H. Huddart, W. G. Hay, J. C. W. Humfrey, Francis E. Baron, A. M. Lodge, Henry Fowler, H. Owens, J. Walwyn White, Charles Stewart, C. A. Charlewood, and R. Edgar Boulton. In addition to these the following gentlemen were observers held in reserve in case of accident:—Robert Nelson, J. Bibby, Captain R. S. Walker, and W. S. Bushell.

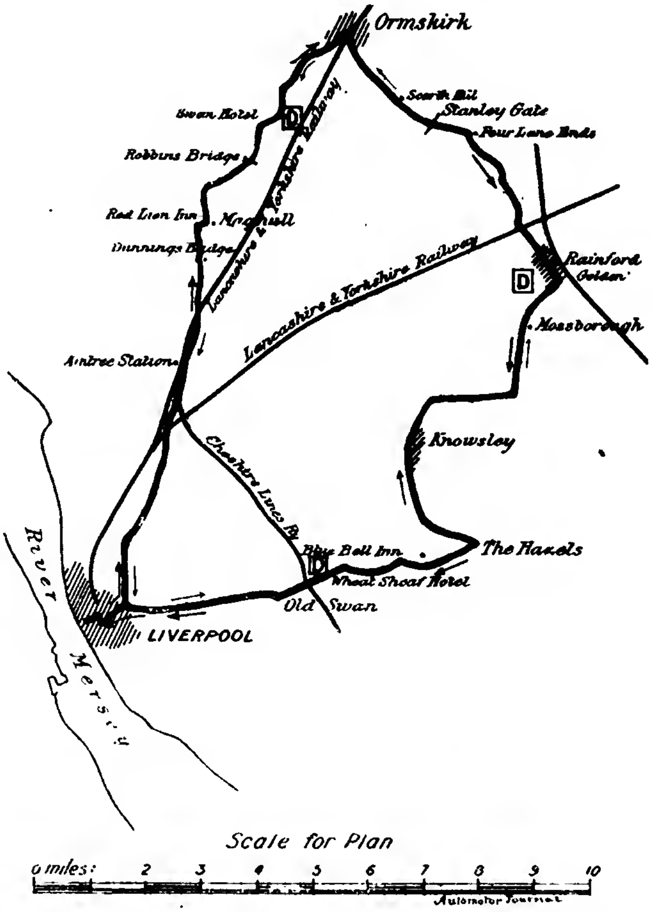
For the convenience of the judges, guests, and the Press there were several motor-vehicles provided, kindly lent for the occasion by the Daimler Company, who was represented by Mr. Critchley, the Blackpool Motor Company, &c. Messrs. Phillipson and Toward, of Newcastle, sent their steam wagonette, and the Llandudno Touring Company sent a Benz Motor wagonette. Mr. Sturmey, of the *Autocar*, was present with his well appointed Daimler, and had no lack of passengers. Particular attention must be given to the judges' wagonette; this was a magnificent Daimler, and it ran most admirably throughout the trials. It formed indeed an object lesson to the Liverpool people, especially to those who indulge in carriages. The advantages of dispensing with expensive and gorgeous coachmen and magnificent horses were plain enough, and we heard more than one wealthy magnate declare that after seeing this well-appointed Daimler he should give up his expensive stables.

Tuesday, May 26th, was a glorious day, with a fine westerly breeze blowing. At the Prince's Dock—the chief depôt—was assembled a crowd of shipowners, engineers, merchants, master carmen, journalists, and of others interested in the trials. One recalled mentally a somewhat similar scene that occurred some 60 years ago, when the first railway out of Liverpool was opened. Then, as now, a small band of men were waging the eternal and never-ending war of enlightenment against ignorance; then, as now, "ignorance," to quote Schoppenhauer, "sits in high places," "and folly" (still as in so many vital matters) "has the casting vote." Then the new movement of automobilism was bitterly opposed by the "Classes," now the new automobilism is obstructed by the representatives of the "Masses," who, through their County and Parish Councils, exhibit a deplorable ignorance and dislike of much that directly tends to their own moral and material welfare.

How hard is the path of those who have the misfortune to be, in vulgar parlance, "born before their time," is as well exemplified

PLAN OF ROUTE A.

May 24.—*Viâ* Ormskirk and Rainford.
" 25.—*Viâ* Knotty Ash and Rainford.



by the history of automobilism as by the history of civilisation; when we recall how Gurney, Dance, Hancock, and others were derided, thwarted, and finally ruined, because they were soldiers in this war of enlightenment against ignorance. Such thoughts must have passed through the minds of many as they contemplated the four vehicles that represent the progress and enterprise that have been made since the time of the early pioneers. Truly we make haste slowly, and our modern Gurneys and Hancocks have yet to do much—not so much, perhaps, in perfecting their machines, but in the more difficult task of converting the public, and persuading the humble shopkeeper, through his County Council, that with improved roads *his* tea, *his* oil, *his* sugar, can be sold in greater quantities—the people can buy more—*because the cost of the carriage of these commodities is cheaper to his shop.*

Whatever may be the future work of the S.P.T.A., one thing, at least, they might do, and that is organise a staff of lecturers to go through the country expounding the gospel of cheap internal transport and what it means to the working man.

* *See* Les Poids Lourds trials—THE AUTOMOTOR, January and February, 1898.

After all preparations had been made, and the vehicles finally inspected by the judges, a start was made at 9.47 a.m. by No. 3; No. 5 following at 10.6 a.m., No. 4 at 10.17 a.m., and No. 1 at 10.29 a.m.

The routes selected were well calculated to test the capabilities of the various vehicles, partly because the Lancashire roads are worse kept than other county roads, and also because they abound in gradients, some of which are very steep and difficult to negotiate. As will be seen from the accompanying maps, two routes were selected.

Route A was from the Prince's Dock *viâ* Dale Street to Walton, thence following the Ormskirk Road to the village of that name, thence to Rainford, Knowsley, The Hazels, Old Swan, Kensington, London Road, to Lime Street, Dale Street, and Prince's Dock. On this section of the road the steepest gradient is also 1 in 21. The remainder of the road consists of ordinary macadam, which might be in a much better state of repair, the steepest gradient on it being 1 in 32. In addition, the road contains several very abrupt turnings which called for considerable skill in manœuvring. As will be seen, too, the judges had carefully selected the worst possible spots for stopping and restarting. On this route there were three depôts for fuel, water, &c. On May 24th the vehicles traversed this route *viâ* Aintree, Ormskirk, and Rainford, and on the 25th this direction was reversed.

Route B was from Prince's Dock *viâ* Dale Street to Old Swan, Knotty Ash, to Prescot and The Hazels, and so far was the southern and return part of Route A. From Prescot the route was through

Stops „ „ „ S

Rainhill to Great Sankey to Widnes, thence to Hale and Speke to Aighurth, thence *viâ* Park Road, Parliament Street, Castle Street, Water Street, back to Prince's Dock. On this route, which is 35·9 miles in length, there were but about $6\frac{3}{4}$ miles of good paved road, but on many parts of this the gradients were very severe and numerous, there being one of 1 in 21 or about 3°; the remainder of the road was macadam, which in parts, as to the west of Widnes, was in a very bad state of repair. It was little better than what is known in the States as a "dirt" road, and the resistance was certainly not less than 100 lbs. per ton.

route, which is 35·62 miles long, there are about $10\frac{1}{2}$ miles of excellent paved roadway, which, however, contains some gradients varying from 1 in 21, or nearly $2\frac{3}{4}$°. There are then about five miles of mixed paving of an inferior description, often consisting of cobbles and loose stone, not in a very good state as regards surface. On this

Taking the vehicles in their enumerated order, the "Lifu" is a steam propelled lorry, 16 feet 2 inches long, 6 feet 6 inches broad, and 3 feet high. It has 64 square feet of available cargo area. The platform is fitted with a tailboard 5 inches high, and there are also side strakes 3 inches high.

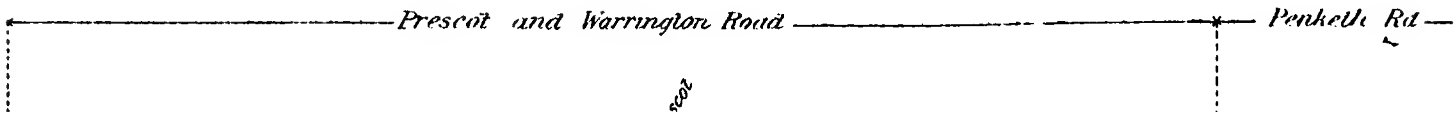
The framing of the "Lifu," as, indeed, of all the competing vehicles, is on the system so persistently advocated in THE AUTOMOTOR, that

SECTION 0

OUTE A.

SECTION O

ROUTE B.



2 c 4

is, it is made of high grade channel steel, thus combining lightness with strength. These longitudinal channels are united by transverse frames and the whole rendered secure against racking stresses by uniting the corners by means of gusset plates. In fact the framing is a small edition of the latest practice in railway carriage building.

The vehicle is carried on plate springs suspended in the usual railway manner, and to these are attached the axles, the fore axle being curved back to admit the lower part of the boiler. It is also bifurcated at the ends, so as to carry bronze bushed pinioned axles. These pinioned axles also carry a bell crank lever so as to permit of steering on Ackermann's principle, the tiller being very conveniently placed to the driver's hand. In order to keep the springs and axles in alignment, so as to prevent any longitudinal motion of the rear or driving axles, these are stayed together by longitudinal steel tube stays, the whole with the upper framing forming a perfectly double-acting pump, working direct from the engine crankshaft by means of reduced speed gear. The other is an injector. The former pump is so arranged that it can be used to fill the boiler by hand without use of steam, if required. Two oil tanks are fitted underneath the vehicle at the rear, each holding 20 gallons. These are filled by means of a funnel fitted with a strainer which extends beyond the vehicle, there is thus no danger whatever of spilling oil on the platform of the car. Two water tanks are fitted, one underneath the driver's seat, holding 60 gallons, and one underneath the platform, holding 75 gallons. These can be filled by means of the steam injector, with a suitable length of hose, in a very few minutes. The burner* is also of the "Lifu" pattern but much improved since we saw it last. There is none of that roaring noise which is so objectionable to hypersensitive people, most of whom, however, would regard the varied sounds of a horse, with their accompaniments, with indifference if not with pleasure. The burner is automatically regulated by the

Fig. 1.—"Lifu" Motor Lorry (No. 1).

rigid and very strong structure to resist deformation yet permitting vertical play. It is no doubt to this well thought out design, for which Mr. H. A. House must have every credit, that much of the good running of the "Lifu" is due. The wheels are of oak with bronze hubs and ash felloes; they are fitted with 3-inch tyres, ½ inch thick. Means are provided for ensuring copious lubrication. The boiler* is placed on the fore part and is suspended from the channel frames; it is of the well known "Lifu" type, *i.e.*, it is a water-tuber having 80 square feet of heating surface, the working pressure is 250 lbs. per square inch, and is rated as a 25 I.H.P. boiler. Its construction permits of easy examination and cleaning, and in the event of a tube bursting a new one can be inserted or the holes plugged in a very short time.

The boiler contains 16 gallons of water, and it can evaporate if forced as much as 50 gallons per hour; during the trials the evaporation was about 35 gallons per hour. Its weight in working order is about 700 lbs. There are two feed pumps, one being a steam pressure so that, should the steam go up over the working pressure, the supply of oil is checked, and as the pressure falls more oil is allowed to flow to the burner. The motor is a horizontal compound one of simple but strong construction, it is illustrated on p. 362. As will be seen, many improvements are embodied in the latest design, special means being taken to prevent the lubricating oil from reaching any hot surfaces and so vaporising and giving off an objectionable smell. The piston rods are made longer and pass through double glands. The engine runs at 600 revs. per minute, which gives a speed of eight miles per hour on a level road. The ratio of gearing is about eight to one. We should say that the cranks, crossheads, connecting-rods, eccentrics, and pump gears run in dustproof oil cases, which are half filled with oil, and so arranged that the water from the piston-rods cannot mix with the oil. No condenser is carried, but the exhaust steam is superheated and passes out of the funnel in an invisible vapour. The exhaust is also practically noiseless.

The power is transmitted to the driving shaft by means of steel cut bevel gears running in oil cases made dust-proof, provided with long white metal bearings, and a mild steel shaft made telescopic to

* *Vide* The Automotor, June, 1897; and The Automotor Pocket-Book, pp. 110 and 180.

allow for the action of springs and unevenness of roads. The countershaft is fitted with compensating gears to allow for turning curves, having long white metal bearings, well lubricated and dust-proof, bolted to the stiff frame to which the springs are fastened. This shaft is fitted with steel pinions on each end, running in large steel internal cut gears securely fastened to the spokes of each of the rear wheels. The countershaft is fitted and supported by two steel reaches fastened to front and rear axles. There is no changing of gears for different speeds, the regulating of speed being accomplished by means of the high-pressure cylinder steam valve, but when extra power is required high-pressure steam is let into the low-pressure cylinder. The large gears on the rear wheel are enclosed in mud guards securely fastened to the axles, thereby preventing any grit from getting into the gears. The brake power roads on the routes, Mr. House decided to fit much stronger and broader tyred wheels, and although, as the event showed, this was a wise and prudent course, it nevertheless brought the weight of the vehicle beyond the 2 tons limit. Under normal conditions this vehicle is capable of attaining a speed of eight miles per hour on fairly level roads when fully loaded, and of climbing grades of 1 in 10 at the rate of four miles per hour fully loaded. We may say that the whole vehicle was designed by and built under the supervision of Mr. H. A. House, jun., M.I.M.E., Engineer-in-Chief of the "Lifu" Company.

Throughout the trials the "Lifu" No. 1 ran most excellently and left nothing to be desired from the carman's point of view. At no time was there any visible vapour from the funnel—or at any rate none worth noting. The steam was raised in 25 minutes to 210 lbs.

FIG. 2.—THORNYCROFT'S SIX-WHEELED ARTICULATED STEAM LORRY NO. 3)

is unusually ample; not only does the reversing of the engines act as a powerful brake (the reversing lever properly handled permitting almost any pressure on the wheels), but in addition to this an emergency brake is fitted and arranged as a foot brake which acts dire t on the rear wheels by means of steel bands around the large gears fastened to the rear wheels. This emergency brake is capable of holding the wheels when the vehicle is fully loaded. Sand boxes are arranged that, when necessary, sand can be deposited directly in front of the driving wheels. They are worked from the driver's seat. In cases of starting or stopping suddenly on wet or slippery roads, and also for climbing hills where the rear wheels are inclined to slip, this has proved a most useful feature in the design.

The weight of the vehicle complete, without fuel or water, is stated by the makers as 38½ cwt., and with the full supply of oil and water 54 cwt. In view of the exceedingly trying nature of the per square inch, and was easily maintained at any required pressure according to the nature of the road. The gradients were for the most part, and all but the steepest, ascended at speeds which a three-horse loaded lorry could not possibly attain. At the same time one or two incidents occurred which gave useful lessons in practical experience. On one occasion a screwed plug on the separator worked loose and fell out; it was, however, happily recovered. On another, when travelling at a good speed closely followed by a light vehicle conveying guests, the official observer gave the order to stop, this was effected so quickly that the following vehicle ran into the "Lifu," damaging the tailboard of the latter and also the reserve oil fuel tank which is carried in the rear; much of the oil was lost, but the progress of the vehicle was in no way impeded. In the former case the lesson is that check nuts and split pins should always be used, and in the latter oil tanks should be fully protected with stout cleading. A more serious mishap was the blowing out of the low-pressure cylinder cover; this occurred just after leaving the depôt at Rainford on the 27th, and was due to the presence of condensed steam in the cylinder. The vehicle, however, came home at the normal speed, but, of course, exhausting into the atmosphere. Mr. H. A. House, however, promptly wired for another cover, and this was in place in time for the next day's run, which was accomplished without any mishap. On another occasion, when bringing up at a depôt, the vehicle being steered off the main road got on some soft ground and stuck; by unloading part of the ballast and with the willing aid of the villagers and guests the vehicle was quickly extricated. This incident shows the important influence that the road exercises on this question of heavy vehicle propulsion. Had it not been that the weather was fine and the roads dry it is certain that on that very bad piece of road just outside Widnes No. 5 would have found some difficulty in getting over a road which is little better than a dirty dust heap in fine weather and a filthy slough in wet weather.

A minor mishap was the breaking of a gauge glass, but, as two water gauges are fitted, this was of no moment.

Notwithstanding the excellent performance of No. 1, much of it will have to be discounted by the judges, as owing to the weight unladen being over 2 tons (it actually was 2 tons 7 cwt. 3 qrs.) the speed attained was on several occasions greatly in excess of that allowed by the regulations of the Local Government Board. By Article IV the speed for a vehicle weighing over 2 tons is restricted to five miles per hour. The "Lifu" actually at times made over nine miles per hour, and her average for all the runs is 8·02.

No. 3 was a Thornycroft six-wheeled articulated steam lorry, built by the Steam Carriage and Wagon Company, of Chiswick. It is intended to carry loads up to 5 tons at a speed of about five miles per hour up a gradient of 1 in 18. It has a platform area of 110 square feet, and the tare weight is 3 tons 19½ cwt. In running order this is increased to 4 tons 5 cwt.

The chief feature of this vehicle is the flexibility afforded by this articulated joint. Really this lorry consists of two vehicles. As will be seen, the one in front is the tractor and the one in the rear the trailer; the two are united by a peculiar universal joint or turn-table which permits the two vehicles to occupy different places longitudinally and horizontally relatively to each other. The tractor is built on framings of channel steel, well tied together by transverse and diagonal frames. The trailer is indeed much like an ordinary Liverpool lorry, in that it is merely a platform. It is fitted with a powerful steam brake which consists of a steam cylinder, the piston rod of which is connected with two hanging brakes. The wheels consist of T-rings surrounded by an outer tyre; this latter is riveted to the flanges of the T-iron. A little consideration will show that this design is questionable, as there is a tendency for the outer tyre to become slightly larger than the inner T-ring, with the result of unduly stressing the rivets. This seemed to have occurred with some of the wheels, as a few rivets had to be replaced or headed up during the trials. The spokes are of twisted bar, and arranged alternately on the two flanges of the hub. On the front part of the tractor is a kind of cabin in which is the boiler, feed-pump, &c. On the front again of this cabin is a coal bunker. On the roof of the cabin is an air condenser* made of light copper tubing. We understand that this condenser will condense about two-thirds of the exhaust steam. It strikes us, however, that the efficiency of this condenser is much impaired owing to its vicinity to the funnel, the hot gases from the latter being discharged just over the tubes. It is, however, useful, as it prevents very largely any great deposition of lime salts on the boiler tubes. It also acts as a silencer, as the blow-off both from the safety-valve and the ordinary exhaust pass into it; and although all the steam may not be condensed, its pressure is reduced to atmospheric.

FIG. 3.—THORNYCROFT'S SIX-WHEELED LORRY (No. 3). Plan.

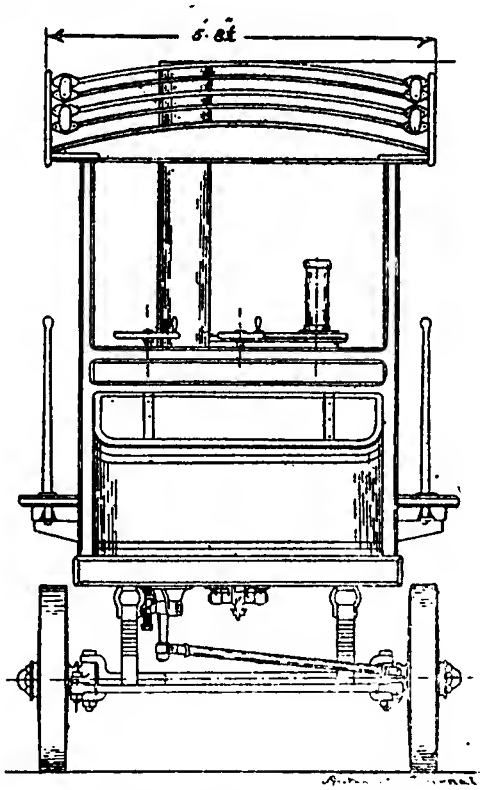


FIG. 4.—THORNYCROFT NOS. 3 AND 4 (Front View).

The boiler is of the annular vertical water-tube type, and is an improved modification of that previously described by us in THE AUTOMOTOR.*

We illustrate the present design of this boiler in the figures on next page.

As will be seen, this boiler consists of a circular D tube at the

* *Vide* THE AUTOMOTOR, April, 1898.

* *Vide* THE AUTOMOTOR, October, 1897.

bottom connected by tubes to an annular chamber above. The firing-hole is in the centre and the funnel at the side; it has 65 square feet of heating surface and 2½ square feet of grate area. It is worked with induced draught—a unique thing in automobilism—a small fan worked by a band from an intermediate shaft supplying the draught.

THORNYCROFT'S BOILER.

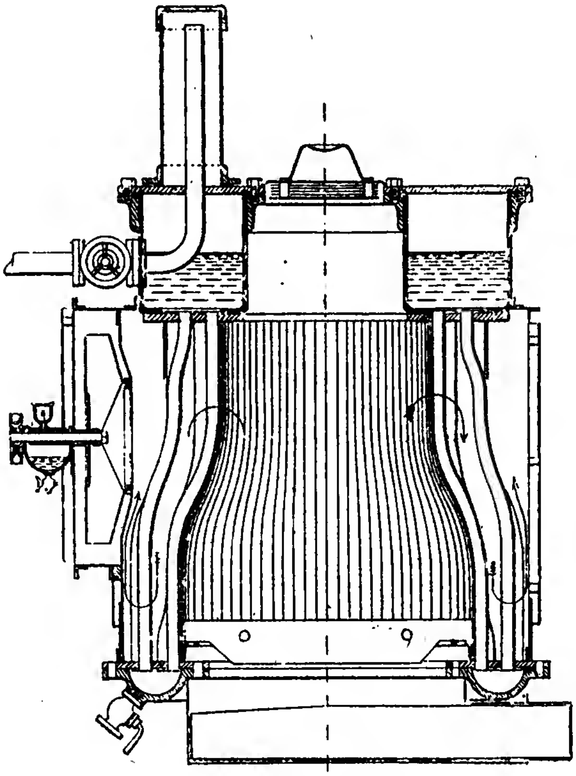

FIG. 5.—Vertical Section.

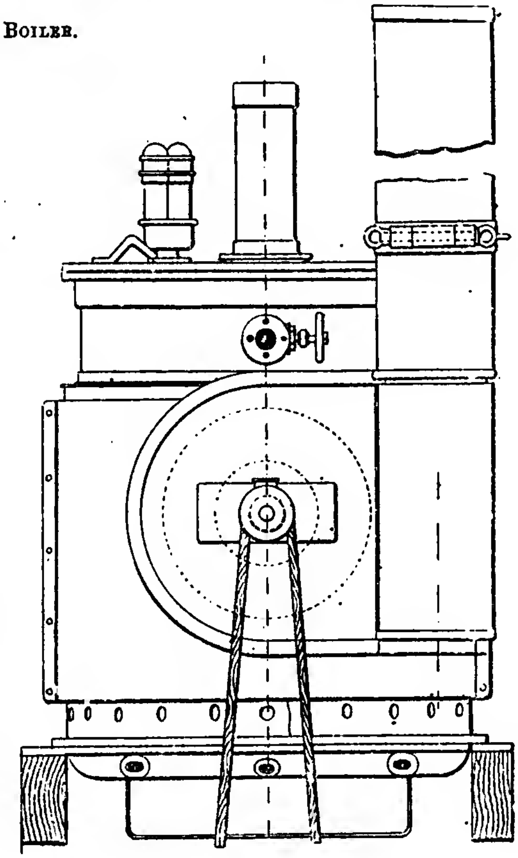

FIG. 6.—Side Elevation.

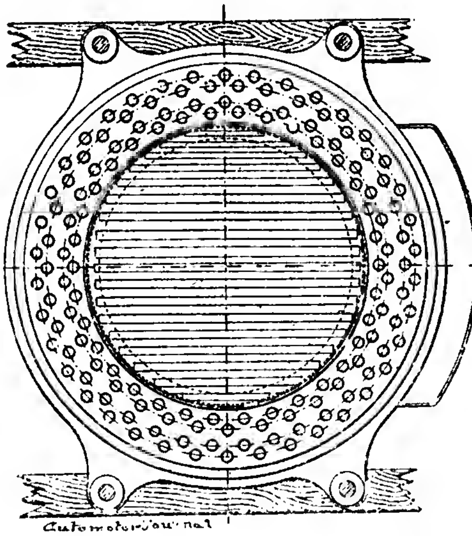

FIG. 7.—Plan on Tube Plate.

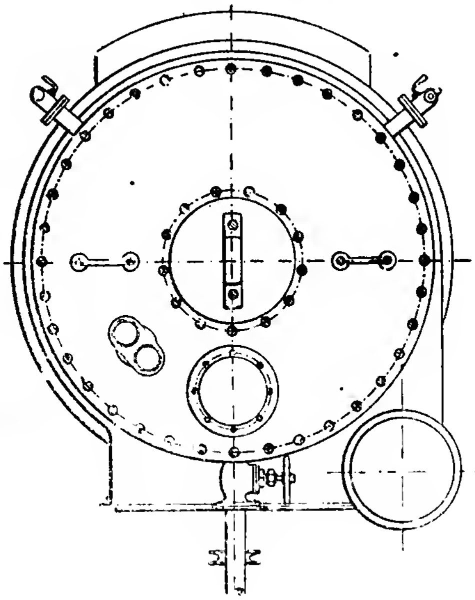

FIG. 8.—Top Plan.

The ordinary boiler pressure is 175 lbs. per square inch, which is half the test pressure. The fuel used is steam coal or coke, and steam can be raised in 15 minutes. The main-feed pump is worked off the engine shaft by gearing, and gives a constant feed at each speed of the engine. An independent "Blake" pump is also fitted for pumping up the boiler when the vehicle is standing. The motor is a horizontal compound, the cylinder being 4″ + 7″ × 5″. A bye-pass valve is fitted so that, if necessary, steam can be admitted to the low-pressure cylinder direct. The engine runs at 400 revs. per minute. It is enclosed in a dust-tight casing, the pinion on the main shaft gears into the driving wheel of the differential gear, and two other pinions, with helical teeth, on the shaft of this latter transmits by means of Renold's chain the motion to the rear driving wheel, the ratio between the engine shaft and driving wheel being 9—1 for the first speed and 12—1 for the second.

A feature about the Thornycroft tractors, although but a detail, is that as far as possible rods are dispensed with for working cocks, &c. In their place are light steel-wire leads, such as are used for opening and closing certain valves and cocks on board war vessels.

different kinds of work. Or a dynamo can also be fitted, so that, when stationary, the engine can be used to supply current; or again, the motor-part could be easily so arranged as to drive agricultural machinery generally. No. 4 is fitted with one speed only, and has double-helical gearing, giving very smooth running; otherwise, the particulars given to No. 3 apply also to this.

No. 3, the Thornycroft 5-tonner, ran very well considering the heavy load—some 9 tons—that had to be moved and the execrable nature of many of the roads. The boiler made plenty of steam, and from "all cold" a pressure of 175 lbs. per square inch was obtained in 19 minutes. The condenser, owing to the vicinity of the funnel and the rather high air temperature, did not seem to be of much service, and it was necessary to stop several times in order to take in water, the tank accommodation being rather too limited. The vehicle would

Fig. 9.—Thornycroft Lorry (No. 4).

No. 4 was also a Thornycroft lorry from the same builders. It is a four-wheeled vehicle designed for a load of 3 tons on the level at a speed of six to eight miles per hour. The platform or deck area is 60 square feet; the tare is 2 tons 19 cwt. in light and 3 tons 4½ cwt. in working order. It is unnecessary to describe the vehicle at length as the dimensions of the machinery, heating surface of the boiler, &c., are the same as in No. 3. Indeed, so far as the machinery and motive power are concerned, one design applies to all the various Thornycroft vehicles, the object of this design being that any particular kind of body can be placed upon the rear platform; thus in No. 4 the timber afterpart can be removed in a few minutes, and a steel tipping body, or watering-tank and fittings, or other spare bodies substituted for it; this will be seen to be an important advantage, as a user can, with one motor-part and under-frame and several spare after-bodies of various design, execute many

undoubtedly have completed the trials had it not been for her wheels. On the first day, when near home, one of the outer tyres came right off through the riveting giving way. A blacksmith effected some repairs, but the wheel again gave trouble, and ultimately some of the ballast was jettisoned and the vehicle returned light. On the second day she did not run, but on the third and concluding days she ran remarkably well, making nearly an average speed of 4 miles per hour; thus, eliminating the wheel trouble, there is no doubt but that this vehicle can be regarded as demonstrating beyond cavil that loads of 5 tons can be carried at a really very good speed on exceptionally steep roads. Messrs. Thornycroft have, by demonstrating this fact, done more than anyone else to carry out the objects of the S.P.T.A., and to them belongs the credit of being the first firm to do this since the passing of the Locomotives on Highways Act. As regards the trouble with the wheels, this is purely a question of design, and to such a firm, with its world-wide reputation for the very hest material and workmanship, this problem will, wo are sure, be adoquately worked out, and on original lines at that.

On the 27th a slight mishap occurred through a leaky tuhe, but this was quickly plugged, and nothing further happened. Some roughs, doubtless instigated thereto hy certain evil disposed members of the "horsey cult," attempted to board tbe car just outside Liverpool, hut were gallantly repulsed, one of tbe "unwashed" heing gracefully deposited in a horse-trough. On such occasions the conductors of steam vehicles would do well to keep the feed hose coupled up to the hlow-off cock. It is very curious to note tho extraordinary dispersive power of high-pressure steam on a moh. We have tried it.

On one point, however, No. 3 is disappointing, and that is her manœuvring power; this came out rather painfully at the trials held on the 28th, of these we speak later on. It is sufficient to say that No. 3 wonld not, in its present articulated form, do for dock work, but it is also only right to say that Mr. Thornycroft's idea in adopting this special design was to insure sufficient adhesion on his driving wheels, and, so far as this purpose was concerned, no trouhle was experienced, as a little sand enabled the vehicle to climh the stiffest gradients.

tremendously heavy—about the heaviest wheels we have seen; the tyres are 5 inches wide and nearly 1 inch in thickness. In spite of their size and apparent strength these wheels gave great trouhle, and one had to he replaced. On the front part of the platform is a cabin in which are placed the hoiler and engines, the former is of the vertical fire tube type and has 110 square feet of heating surface, the weight per square foot of heating surface being 6 lbs.; the working steam pressure heing 200 lbs. per square inch. The boiler is fired with liquid fuel, the burner being very quiet in its action; the supply of oil is regulated hy the steam pressure acting upon a diaphragm valve. Steam can he raised from "all cold" in 18 minutes. The engines are vertical uni-direction compound, entirely closed in and running in oil. They drive by means of pinions a second motion shaft which hy means of chain drives a third, which by chain gearing transmits the motion to the driving wheels. For reversing speed wheels are fitted on the second motion shaft, on which is also the differential gear. All the machinery is placed underneath the platform and is readily accessihle. The exhaust steam goes to an air condenser placed on the roof of the cabin, and it seemed to act fairly well. Powerful brakes are fitted to the driving wheels worked hy screw gear from the front. These brakes will hold the vehicle loaded on an incline of one in seven.

No. 5 was, on the whole, rather unfortunate, the wheels giving a great deal of trouhle. As we have said, these are of wood and unusually heavy. Indeed a little reflection will show that wooden wheels, as ordinarily made for wagons, are not suitable for driving wheels of locomotives. On the first day of the trials both tyres of the driving wheels came off, and later on one wheel broke up entirely; the vehicle ultimately arriving at half-past ten at night. A new wheel, the left rear, was shipped in place tbe next day, and a very excellent run was made, the average speed being nearly 5¼ miles per hour. Towards the end of the run a tyre got slack, and so it was determined to thoroughly overhaul the wheels; this occupied the whole of the third day, hut on the fourth and last day a very good run was made. The machinery ran perfectly throughout, and gave no trouble whatever. Steam can he raised to 200 lbs. in about 22 minutes. It would seem, however, desirable to carry larger oil tanks for supplying the hurner, as on one occasion the furnace was extinguished through lack of oil. In all other respects this vehicle behaved remarkably well. The load, 4 tons, was sufficiently trying, but had the wheels been more suitahle there is no doubt that this vehicle would have gone through each day's trial most successfully. The failure to effect this is to bo regretted, but after providing suitable wheels, Mr. Spurrier has in No. 5 a thoroughly good and practical vehicle.

FIG. 10.—THE LANCASHIRE STEAM MOTOR LORRY (No. 5).

No. 4 had a few mishaps hut nothing of a really serious nature. On the first day, when near Ormskirk, a hoiler tube burst, this necessitated blowing blown and opening out tho boiler. Mr. J. E. Thornycroft, however, has had too much torpedo-hoat experience to allow a burst tube to interfere with him, and he and his two ahle assistants had it plugged in a very short time, drawing the fire and relighting, however, meant another 56 lbs. of fuel. On the third day No. 4 had a mishap which, we think, will often be experienced unless the hearings, &c., are made unusually long and ample lubrication is assured. The fan for working the induced draught gave out, the hearings seizing. This, however, did not seem to make much difference as regards the steam pressure, as sufficient draught was created hy turning a steam blast into the funnel. It occurs to us, however, that the fitting of a fan is of doubtful advantage. Trouhle, as mentioned above, was also experienced with the wheels, hut these, we understand, are only experimental ones, and Messrs. Thornycroft have entirely new designs in hand. It may also he doubted whether hall hearings are suitahle for such vehicles.

No. 5 was entered by the Lancashire Steam Motor Company, of Leyland. It is designed for a load of 4 tons. It is a four-wheeled vehicle having an available platform area for goods of 78 square feet. This platform has folding sides something similar to a railway truck, and is carried on channel steel frames, these are well braced and tied together. This platform is supported hy douhle plate springs to which are attached the axles. The wheels are of wood and are

The manœuvring trials took place on the 28th at the principal depôt at the Prince's Dock, in the presence of Professor Hele-Shaw, who acted as judge. A distance about the length and a half of a vehicle was marked off against a wall hy a couple of fences placed at right angles to it, and it was required that each vehicle should be placed close alongside the wall between the two fences. A Liverpool carman with a pair of horses and a lorry would have dono this easily without the aid of any profanity. To the conductors of the motor-vehicles it was a hy no means easy task. Mr. Spurrier, in tho Leyland No. 5, was tbe first to essay the feat; hy judiciously "filling and backing" he accomplished it successfully; but, owing to the cabin in this vehicle having no windows in the hack, it is impossible for the man at the wheel to see how the rear is going, and a less careful and deliberate man than Mr. Spurrier would probably have done a good deal of damage before getting into position. No. 1, under Mr. House, then attempted the task, but it was not till after many efforts that he succeeded in accomplishing it. No. 4 also occupied much time in getting into place. This difficulty in entering an embayment is one that can only be got over by individual experience. Just as at a railway goods station, as one can see any day, some carmen will "back up" with certainty and ease, others will take much time and tear their horses' mouths to pieces in their efforts to get into position. It does not, therefore, depend so much upon the vehicle as upon the driver. With No. 3 the case was altogether different. This is, as before stated, an articulated vehicle, and to manœuvre such into such a path was, as it is needless to explain, an almost impossible task, and it occupied the better part of an hour to effect. It is for this reason that we think that articulated vehicles quite unsuited for dock work.

The following is the official abstract of the log of each vehicle during each day's run:—

this nomenclature is now obsolete and not now used by high-class engineering firms we have expressed these quantities in decimal notation for the convenience of engineers and of our French readers who may desire to express them in metric units for the purpose of making comparisons with the performances of other vehicles. These matters may appear trivial, but we think it right to inculcate the convenience of the decimal and metric systems, and we would here suggest to the S.P.T.A. that the value of the report of these trials would be much enhanced if all quantities were expressed in decimal notation and their values given in metric units.

Although we have not sufficient data to enable our readers to form an independent judgment on the trials it is not difficult to reach certain conclusions; and in order that our readers may be

The information contained in the above tables is all that has been vouchsafed to us officially.

In these tables, as originally furnished to us, distances were expressed in miles and furlongs and weights in avoirdupois. As

enabled to form some approximately accurate estimate of the performances of the various vehicles we have compiled the following table which we have every reason to regard as correct under the conditions for which it is prepared. These are:—Coal is taken at

15s. per ton, petroleum at 3½d. per gallon, and water at Liverpool at 7d. per 100 gallons.* We bave taken the performances, loads, &c., of eacb vehicle and made average values.

After tbe manœuvring trials referred to above tbe vebicles were weighed, and this concluded the proceedings.

Official Tare Weights of Vehicles.

19. " motive power " "	"	1·291	·464	·394	·512

A study of tbe above tahle is interesting as several important facts are revealed by it. It will be seeu that the Tbornycroft No. 3 (*see* line 4) represented a moving weight of no less than 9 tons, or, assuming tbe load equally distributed (which it was not), 1·5 tons per axle. In No. 5 the total moving weight was 7·35 tons, or 1·84 tons per axle. In tbis vehicle it is more tban probable tbat there were 5 tons on the driving axle, and the balance on the front axle; this would give about 3 tons per driving wheel, and tbis fact, coupled with the stresses set up in transmitting the power, would account for the practical disintegration of one of the wheels of tbis vebicle. It is, however, bootless to follow tbis important matter up, as we cannot say what is tbe actual weigbt on the drivers.

Referring to tbe ratio between the weight of the cargo carried and tbe gross moving weight, line 5, it will be seen that wbile tbis ratio may approach unity it can never become unity, but tbe nearer it approaches unity tbe greater (otber things being equal) is the efficiency of tbe macbine. From this point of view No. 5 is surprisingly good, no less than 60 per cent. of the total weight being paying load. No. 3 approacbes this, but both are mnch ahead of No. 4 by something like 10 per cent., and ahead of No. 1 by some 16 per cent. This comparison sbows that the same law holds good for road vehicles as for marine vehicles, regarding both from the owners' point of view; that is, more freight can be earned by transporting a large quantity of goods at a low speed tban by carrying a smaller quantity at a higher speed. Tbus it will be seen tbat whereas No. 3 carried nearly 2½ times as much cargo as No. 1 her speed was but one-half that of No. 1, yet tbe horse-power of both vehicles was nearly alike. We may then conclude that it will pay carriers better to employ vebicles which will carry at least 5 tons of goods than lighter vehicles. It will he noticed that the average speeds, line 9, vary greatly. Considering the load, No. 5 again comes in for commendation. It is a distinctly better performance to carry 4 tons at a speed of nearly 5¼ miles per hour than it is to carry 2 tons at 8 miles per hour. Indeed No. 5 is in tbis connection a long way ahead of the others. Coming to the consumption data, lines 10-15, it will be noticed tbat although the ton miles for cargo of Nos. 1 and 5 are practically alike, yet the consumption of petroleum per ton mile in No. 1 is two and a half times that in No. 5; wbile tbe consumption of water is nearly tbree times as great in No. 1 as in No. 5. We should he inclined to doubt the accuracy of the figures relating to No. 5 were it not tbat in both vehicles the consumption of water per unit of petroleum is nearly alike, thus No. 1 consumes 6·9 units of water per unit of petroleum, and No. 5 6·5 units. The net result is tbat the cost of motive power per ton mile of cargo iu No. 1 is twice as great as in No. 5.

As regards the two coal burning vehicles, Nos. 3 and 4, the figures are, we think, remarkably good, hut in order to institute a proper comparison we give in tbe following table some figures relating to two otber vehicles, viz., the celebrated "Ravee," tried in 1871,* and the tractor trailer Scotte No. 2, one of the competing vehicles in Les Poids Lourds Competition at Paris last year:—

—	"Ravee."	Scotte No. 2.	Thornycroft No. 3.
Total moving weight in tons	19	11·51	9·09
Consumpt of fuel in lbs. per ton mile of total weight	8·63 (coal)	2·0 (coke)	2·8 (coal and coke)
Consumpt of water in lbs. per ton mile of total weigbt	17·17	10·7	9·94

It will he seen that a very noticeahle advance has been made since 1871 in the directions indicated. As regards the quantity of water evaporated per pound of fuel, the "Ravee's" hoiler would evaporate from 4·7 to 5·7 lbs. of water, while the Scotte evaporated 5·5 lbs. We have not yet tbe figures for the Tbornycroft hoiler before us, but we think they will not differ materially from those relating to tbe Scotte boiler.

Finally we have to consider the cost of the motive power. As will he seen on line 19, No. 4 costs the least of any, the fuel and water costing less tban ½d. per ton mile of cargo carried. No. 3 is also less than ½d. No. 5 is just a little more, while No. 1 costs more than 1¼d. per ton mile of cargo.

It will also be noticed that the cost of working boilers burning liquid fuel is much higher thau for coal fired boilers.

It is of course understood tbat our figures by no means represent the actual cost of working each vehicle; this can only be reached by discussing all the data—prime cost, depreciation, interest, wages, &c., but sufficient has been said to give those interested some idea of the nature of the problems involved in the question of Motor-vehicles v. Horse-drawn Vehicles for heavy traffic.

* This is the price at which water is delivered to the shipping in the docks at Liverpool.—ED.

* *Vide* Fletcher's "Steam on Common Roads," p. 196.

As is well known, Liverpool is the receiving depôt for practically the whole of the cotton used in the Lancashire district, *i.e.*, nearly all the cotton imported into England is through Liverpool. Should a service of steam vehicles be inaugurated and put in successful operation, it becomes interesting to consider how many bales the vehicles taking part in these trials could carry.

The average American (U.S.) cotton bale bulks about 31 cubic feet, and weighs 490 lbs., or 4·57 bales per ton. No. 1 vehicle could load 9 bales; No. 3, 23 bales; No. 4, 11 bales; and No. 5, 18 bales.

The trials were closely watched on each day by a large number of members of the S.P.T.A., representatives of railway and cartage companies, guests, &c. Among those present were Messrs. W. A. and Chas. H. Darbishire, A. Holt, Alfred Jones, S. Geogeban, W. Dean (G.W.R.), W. Hucks, A. W. Macleod, J. E. Thornton, Henry Mozley (Burnley and District Tramways Company), W. Bracewell, E. Samuelson, Alderman Greenwood, Hans Renold, A. Musker, Jno. A. Brodie (city engineer), R. C. F. Annett, Ernest Wilcox, Wm. Brodie, C. A. Still (Liverpool Cartowners' Association), G. Huttersley, R. R. Cook, W. H. Deaville, G. F. Borthwick, F. Thompstone, A. Heapy, F. W. Hodges, W. Murray (N.E.R.), W. Maide (N.E.R.), H. A. Butt, C. H. Bland (representing Lord Iveagh), Clifford Muspratt, Edward Samuelson, W. T. Carr and L. Carr (Carr and Co., Carlisle), H. Wardle Rushton, Anthony G. Lyster, Engineer-in-Chief (M.D. and H.B.), C. Melling, D. E. Phipson, Wilfred Webb, Major Dawson, Sidney Straker, A.M., — Mevor, Chas. T. Crowden, — Boyd, — Price, — Riley, Basil Wilson, C. H. Bland, Capt. Johnstone, A. H. King, H. Wardle Rushton, Cyril T. Thring, Henry Burton, James Taylor, — Webb, Henry Ashworth, A. H. Ashworth, — Gossage, — Forbury (Liverpool Cartowners' Association), — Bates, — Russell, Geo. Iden, — Cooke, Jno. Stirling, J. Thorp, — Baines, Jno. Robinson, W. Parkinson, F. A. Robinson, Chas. Manners, R. F. Borthwick, W. G. Chadburn, R. F. Vallance, James Leslie, J. Thorp.

The War Office had appointed Major Hippisley and Captain Johnstone to attend the trials; the former officer was unavoidably absent, and the latter was suffering from indisposition. Their places were taken by Lieutenant-Colonel H. W. Smith-Rewse, R.E., and Captain G. H. Harrison, R.E. Captain Johnstone, however, fortunately recovered in time to witness the trials, thus rendering it unnecessary for Captain Harrison to attend.

Letters of apology for inability to attend were received from the Baron de Zuylen, P.A.C.F.; M. G. Forestier, Engineer-in-Chief Les Ponts et Chaussées; M. Comte Henri de la Valette; M. Comte Chasseloup Laubat, and from other distinguished members of the Automobile Club Française.

The following deputations were officially appointed to attend these trials:—

War Office.—Lieut.-Col. H. W. Smith-Rewse, R.E., Capt. H. F. Gaynor, R.E., Capt. J. A. L. E. Johnstone, R.E.

Post Office.—Francis Salisbury, Esq., Postmaster of Liverpool.

Hull Corporation.—Councillors Hall and Holder, and Mr. Bricknell, Assistant City Engineer.

Wolverhampton Corporation.—Mr. J. W. Bradley, Borough Engineer, with the Chairmen of the Team and Sanitary Committees.

Liverpool Incorporated Chamber of Commerce.—F. C. Danson, Esq., President, Messrs. Alfred L. Jones and Geo. H. Cox, Vice-Presidents, Danson Cunningham, Elisha Smith, J.P., and Thos. H. Barker, Secretary.

Liverpool Cotton Association.—Danson Cunningham, Vice-President, R. W. Brown.

Liverpool Corn Trade Association.—John Blyth.

Liverpool Cartowners' Association.—Messrs. R. Procter, J. M. Garlick, R. Bennett, R. Edwards, Thos. Edwards, J. M. Walker, John Cowx, E. Burns, J. C. Harper, W. H. Robinson, John Davies, F. Norbury.

FIG. 11.—LIVERPOOL HEAVY MOTOR-VEHICLE TRIALS: GROUP TAKEN OUTSIDE THE DEPÔT, AT THE OLD SWAN INN, AUGHTON, BY MR. A. WRAGG, PHOTOGRAPHER, 30, BURSCOUGH STREET, ORMSKIRK.

The Dinner.

In connection with these trials a dinner took place on the evening of Thursday, May 26th, at the Adelphi Hotel, Liverpool. Sir David Salomons, Bart., presided, and he was supported by the Right Hon.

the Lord Mayor of Liverpool (Alderman John Houlding); Mr. Alfred L. Jones and Mr. Alfred Holt, Vice-Presidents of the Liverpool Centre; Mr. R. W. Wallace, Q.C., Chairman of the Automobile Club of Great Britain; M. Pierre Giffard, Membre du Comité de l'Automobile Club de France; M. François Thirz, Bourgomestre de Pecq; F. C. Danson, President Liverpool Chamber of Commerce; W. A. Darbishire, Penybryn, Carnarvon; Charles H. Darbishire; Richard M. Greaves; John I. Thornycroft, Chiswick Mall, W.; John E. Thornycroft; Herbert Niblett; Boverton Redwood, Church End, Finchley, N.; J. E. Thornton, Altrincham, Cheshire; J. P. Lea; Alfred J. Ling, Bollington, near Macclesfield; H. A. House, jun., East Cowes; R. F. Bothwick, Glasgow; H. E. Lytle; S. Geoghegan, Dublin; Francis E. Baron, Blackpool; Julius Harvey, London; Colonel W. Walker, J.P., Liverpool; John Wilson, C.C., Liverpool; Arthur Musker, Bootle; W. Churchward Dean, Swindon; Thomas Dean; Prof. H. S. Hele-Shaw, Liverpool; Anthony G. Lyster, Liverpool; Geo. H. Cox, Birkenhead; J. Walwyn White, Widnes; P. Souvestre, La Société Anonym de Traction "Automobile"; Charles T. Crowden, Leamington; M. C. Bannister, Liverpool; Henry H. West, Liverpool; S. B. Cottrell, Liverpool; J. A. Brodie, Liverpool; G. F. Ransome, Liverpool; Jas. A. Bradshaw, Liverpool; Cyril T. Thring, Dublin; William Hucks, Camden Town, N.W.; F. A. Robinson, Mansfield; Stanley Spooner, AUTOMOTOR JOURNAL; Henry Burton, Newport; A. H. Ashworth, Torton; Henry Spurrier, Leyland; Henry Spurrier, jun., Leyland; A. M. Macleod, Sidcup; J. H. Deakin, Windermere; John Harvey, Manchester; Jesse Ellis, Maidstone; Boverton Redwood, jun., London; T. H. Toulmin; William Philipson, Newcastle-on-Tyne; Thomas Toward, Newcastle-on-Tyne; H. S. Holt; Barras Reed, Newcastle-on-Tyne; J. H. Mace; James Leslie, Belfast; Wilfred le P. Webb, Caterham; G. T. Harrap, London; George Iden; J. Sydney Critchley; J. K. Starley; W. J. Davey; John Rogerson; Alfred Rogers; Sydney Lawson; Cecil E. Hawley; E. H. Gregson; W. B. Wood; J. T. Nicholson; Arthur G. Bean; J. T. Dawes; John Stirling, Hamilton, N.B.; Henry Sturmey; R. C. F. Annet, Sefton Park; Richard Barrett, Liverpool; John Blyth, Liverpool; Miles Kirk Burton, Liverpool; Charles Birchall, Liverpool; R. W. Brown, Liverpool; A. W. Barr, London; James Berry, Prescot; C. Harcourt, Town Clerk, Liverpool; D. Cunningham, Derby; Captain Leonard Dunning, Liverpool; W. Dean, Swindon; John H. Falk, London; Captain H. F. Gaynor, R.E., Chatham; Richard James, G.P.O., Liverpool; Lieut. Henry M. Liardet, R.N., Harbour Master; R. R. Lloyd, London; Thomas Parker; Norman C. Lange, Birkenhead; Edward George Mason, Mayor of Birkenhead; Dr. J. McMurray, Mayor of Bootle; G. B. Proctor, Liverpool; Charles Sandback Parker, Liverpool; C. R. Rowlandson, Manchester; E. A. Rosenheim, Liverpool; W. J. Stewart, Southport; A. T. Squary, Revenue Buildings, W.; Paris Singer, London; Edward Verspreeuven, Belgium Consul, Liverpool; Alderman Waring, Mayor of Widnes; Berkeley D. Wise, Belfast; Seymour B. Tritton; J. Percival Davies.

An excellent dinner having been partaken of, the CHAIRMAN said several letters of apology for non-attendance had been received, and he would ask Mr. Barr to read a letter received from Lord Derby, who enclosed 100 guineas.

Mr. BARR read the letter, which was as follows:—

Derby House, St. James's Square, S.W.,
May 24th, 1898.

My dear Sir,—Please express my sincere regret that I am unable to be present, either at the trials or at the dinner on Thursday. I feel that an apology is due from me for non-attendance, and I am especially sorry not to have an opportunity of welcoming those who have come from a distance, and who have done us the honour of being our guests. I trust that the trials may further demonstrate the advantage of the system of self-propelled traffic, and also may show what are weak points remaining to be remedied.

I have always been a believer in mechanical propulsion on common roads, and, indeed, I believe that a Report which I drafted for a Select Committee of the House of Commons more years ago than I like to think of, somewhere in the '70's, was the foundation for the rule governing the use of locomotives on roads, up to the date of recent legislation.

No doubt there are many difficulties yet to be overcome, and many prejudices to be met, but that self-propelled traffic will make its way I cannot hesitate to believe. It has made its way already in France, where public opinion seems to be ahead of ours. And especially in our own country, where there is much short-distance traffic, and where good roads are not wanting, mechanical traction seems to be almost a certainty.

You are aware, from a previous letter, that my absence is caused by the pressure of a number of engagements which have fallen together in London this week, and which I cannot forego.

The large Consumption Hospital at Brompton, of which I am the titular President, has an important meeting on Thursday, and I am bound to be there in the chair. That is mainly why I cannot join you. There are also four committee and other meetings of the Royal Agricultural Society, of whose council I am a member, to say nothing of other engagements. So that you will see that it is certainly not indifference which keeps me away from our Association meeting.

I wish you all success.

I remain, dear Sir, yours faithfully,
DERBY.

E. Shrapnell Smith, Esq.

Letters of apology were also received from Sir John T. Hibbert, Sir William Houldsworth, Sir John Willox, M.P., Sir John Brunner, Mr. Justice Bigham, Sir Chas. Cayzer, M.P., Sir Elliot Lees, Sir Edward Russell, Sir George Baden-Powell, M.P., Mr. Lawrence, M.P., Mr. Chas. McArthur, M.P., Messrs. Walter Long, A. H. Brown, Samuel Smith, R. Barker, Chas. Galloway, S. Williamson, J. Ernest Graves, R. S. Hippersley, R. P. Houston, W. H. Preece, W. P. Sinclair, W. W. Crosfield, Richard Henderson, Captain Nott Bower, W. E. Sproule, J. P. Brancker.

The CHAIRMAN proposed "The Queen" and the other loyal toasts, "God Save the Queen" and "God Bless the Prince of Wales" being sung.

The CHAIRMAN also proposed the toasts "France," the guests singing "La Marseillaise"; and "Belgium," after which "La Brabançonne" was sung.

Mr. ROGER W. WALLACE, Q.C., next proposed "The City of Liverpool." This, he said, was no mere complimentary toast, but a tribute due to the city, for Liverpool had given every encouragement to commercial undertakings of every sort, and had been foremost in every movement that had for its object the spread of commerce. One illustration of this was the fact that during the past week these motor trials had taken place in Liverpool. It was an interesting fact that during 1897 about 11¼ millions of tons of shipping had cleared from Liverpool. He had been looking back a little, and he found that the trade of Liverpool had been doubling itself about every eight years—it was frightful to think what would be the requirements of the future, but one thing was clear—that some means had to be found for distributing the enormous quantity of produce brought to Liverpool, and that in the quickest and cheapest way which would more easily get it to its destination. Liverpool was in the forefront of that enterprise which brought about the establishment of the Liverpool and Manchester Railway, and one could not help being surprised when one considered how enormous was the impetus given to railways and railway traffic by Liverpool. Unfortunately, the opening of that railway was signalised by the death of Mr. Hutchinson, but he hoped these motor trials would not be marred by any such event. When one remembered the railways and canals that had been constructed by Liverpool and for its trade, and of that canal that had been constructed for Liverpool by another city (laughter and applause), one wondered why Liverpool people should want anything more. But still he thought they were wise. The already enormous traffic of Liverpool must increase. Ships were being built larger and longer than ever, and would be built very much larger still if the Dock Board would give them docks sufficiently large and with the required draught. That was the only limit to the extension in this port. Of course, there must exist a means of taking the goods thus brought to its destination, and why should that means not be the motors they had seen working that day? With regard to the means used for the propulsion of cars, he was forced to believe that electricity was not likely to be successful as yet ("Oh!"), especially in the form of traction they had seen on trial that week. He was obliged to say this, though he was a great admirer of electricity, and used it on his cars. It was a pity that nature had selected the heaviest metal to be the accumulator of electricity, and it would not do unless someone invented a lighter metal for this purpose. He was of opinion that steam would still be the motive power for the class of traffic seen in Liverpool—at all events, he was certain that a large amount of the work would be done by steam. Of course, oil was very cheap, but there remained the difficulty of the fly-wheel, and they could not start the engine and carriage at the same time. That was a very great difficulty, but in the end something might be done in that direction. There were great chances of making rapid strides in this direction, and he thought there was a great future in store for this industry. He also spoke hopefully of the increasing use of aluminium in the construction of cars, but said that the engineering trade was not so brisk as it should be. If they did their work quicker there would be greater progress in this country. In conclusion, he expressed the wish that Liverpool might always prosper, and be always to the front in industrial and commercial matters. Might she always have as popular a Lord Mayor (applause), whose name be coupled with the toast.

The Lord Mayor, in responding, said he remembered the opening of the Manchester Railway, and very proud they were of being able to get to Manchester in three hours—it was a very memorable achievement indeed. Now they got there in 40 minutes. This development was the work of engineers like those who sat around him. He also remembered the wonderful development of the Liverpool and Birkenhead dock systems, and the time when the Liverpool docks were crowded with ships of 500, 600, or 700 tons. Now vessels of 5,000, 6,000, and 7,000 tons were comparatively small steamers, and the journey across the Atlantic was done in six days. This was also due to the engineers and others of inventive genius. Again the wonderful development of the bone-shaker to the perfect cycle of the present day and to the motor-car was the work of gentlemen such as he saw around him. He had witnessed with the greatest interest the arrival at Bordeaux of the motors which competed in the race from Paris and back again, and on the previous Tuesday be first sat in a motor-car. He was not nervous as had been suggested by the previous speaker, because he had been on every kind of railway in Europe, even on the perpendicular rail at Marseilles, so that a simple ride in a motor-car would not make him nervous. They did this first ride of 24 miles, exclusive of stoppages, in two hours, and he never had a more pleasant journey, and never felt more comfortable in any conveyance. If they could only make such improvements in the motor-car as had been made in the steam-engine and in ships he did not know where they would be in 20 years, but be hoped he would be here to see them. (Applause.) He wished the Association every success. He had now certain responsibilities and duties, but when he got back to his old position and had a little more time and fewer responsibilities, he would try what he could—he would do to improve the present system of cart traction by the Corporation. The Corporation was admitted to have the finest horses in the country, but their carts only went along at about two miles an hour; but when they could have 5 or 6 tons taken along at five or six miles an hour behind a machine like that competing in the trials, though the capital cost would be more, he felt sure there would be a great saving in revenue. (Applause.) He believed there was a great future for the motor-car. He would do all he could with pleasure in the interests of the Association. (Hear, hear.)

Mr. F. C. Danson gave the toast of "Self-Propelled Traffic." He said it was a most wonderful thing that until about 18 months ago legislative restrictions were so great in this country that motor-cars were almost an impossibility. They had to be preceded by a man with a red flag, and also accompanied by a degree of noise such

The Thornycroft Tipping Dust Van.

This vehicle has the same mechanism as Nos. 3 and 4, the only difference being that a tipping van is affixed, as shown, to the rear end.

as one might find accompanying a Sunday School procession, and their pace was the right thing for a funeral procession. Within the past two years, since there was a proposal to remove these restrictions, their engineers had been exercising their ingenuity, and with wonderful success. However, the industry was still in its infancy, but its infancy was most promising. There were doubtless difficulties in the way of the adoption of the motor-car for general use, but these would be overcome. When the railways were started it was said that horses would be relegated to the Zoo or the Museum, and the same was now said with reference to the motor-car. But there were more horses now than when railways were inaugurated, and the same would be the case, he thought, even after the motor-car was in general use. There were certain things a motor-car was adapted for and other things it would not do. As a commercial institution the motor-car was bound to make its way, and he had no hesitation in saying it would form a most important factor in the development of the trade of this port and of the country. Speaking of the means by which the restrictions to the use of motor-cars had been removed, he said they had one champion who took up the matter and urged upon all sides the necessity there was to remove all such restrictions. He succeeded in getting the necessary legislation, and finally inaugurated the Society under whose auspices they were gathered there that evening. He became the chief of the Society, the success of which was very largely due to the very able manner in which he had conducted its affairs. (Applause.) He need hardly say he referred to their worthy President, Sir David Salomons (renewed applause), and he had pleasure in coupling his name with the toast. There was another gentleman present who was foremost in doing anything he possibly could to promote any industry or undertaking which was likely to benefit the commerce of Liverpool and of England itself. (Applause.) He had tremendous energy, great influence, and he was fortunate in being able to assist with a very long purse. He was well known and appreciated not only there and in England but in many other parts of the world—he referred to Mr. Alfred L. Jones. He would ask them to drink to the success of the Self-Propelled Traffic Association, coupled with the names of Sir David Salomons and Mr. A. L. Jones.

Sir DAVID SALOMONS said he believed he was the right man to reply to this toast because he had his heart in the movement. They all believed that the extension of the motor traffic would be for the benefit of mankind in a trade or profession or in private life. They knew they had to convert a very large number of people who were—well, he would not call them enemies, but men who were ignorant of the value of motors. He would give the names of the chief amongst these, though these did not by any means include the whole of the classes they included a large number. These were the county councils and other local authorities, who thought that those interested in the motor traffic would demand better roads, and so cause the rates to be a little extra and probably jeopardise their seats on the council or board at the next election. They did not honestly tell their constituents that supposing they did pay a farthing in the pound extra, they would get their goods from the shops a trifle cheaper and quicker, and would save that farthing in the pound in the long run. (Applause.) Liverpool might well be proud that she had set others an example in showing for the first time a motor-car such as they had now—not the first motor-car, for they would have to go back to the days of Hancock for that. Indeed, France claimed the first, and it was difficult to say which was really first, and they must try and give credit where it was due. Everyone was once a little baby—a useless little article. (Laughter.) They were proud that Liverpool was the birthplace of the first railway—though he must really deny that, for the first engine ran in

THE "LIFU" WAGONETTE.

The illustration represents the lighter type of vehicle made by the Liquid Fuel Engineering Company, of Cowes, Isle of Wight.

the county of Kent (laughter and applause), and it was built by Stephenson. However, he did not pretend to deny that Liverpool had given a great impetus to the railway, and in the same way Liverpool had given the motor-car industry a great impetus by the fact of these trials taking place here, and those who were present were to be congratulated on their coming forward at this time. (Applause.) In their earlier days they had learned that there was nothing like leather, and now they knew there was nothing like wheels. (Applause and laughter.) Those who had gone in for these trials had done more than gain experience or give it to others. They had not got to perfection, and as long as they lived they hoped that perfection would not be attained—there would then be nothing to live for. (Hear, hear.) Perhaps he should say very little of the Association, as he was so much connected with it, but he would say that at the moment when nobody would take an interest in getting a Bill through Parliament, the existence of such an Association became an absolute necessity, and it could only be made a success by getting a large number of influential and well-known men, having no financial interests in it, to take the matter up, so that no member could rise in his seat in Parliament and say that so and so were doing this to enrich themselves at the cost of the public. (Applause.) He felt confident that now people would recognise how useful the Association was, and what a good work it had performed. The Association, he thought, had been an undoubted success. Since his visit to this city he had been brought prominently forward, and where he had done those things that were right he might say it was due to the promptings of their man of genius here—the hon. secretary. (Loud applause.) He had been his (the speaker's) guiding star, and he trusted Mr. Shrapnell Smith would be a comet leaving a bright tail behind him as he went through life. (Renewed applause.) He wished to refer to one point regarding which even their friends might do harm—that was with regard to the rules regulating the use of these motors. They wanted changes, but perhaps these changes might be accompanied by restrictions which would do them harm. Wait until the present rules were tried on a larger scale than was possible at present, before they asked for any change. This was a memorable era in the history of horseless carriages. It was a starting point from which they should all combine for the common good. Their strength should be applied in one direction. Mr. A. L. Jones would now speak. He was a master of his own particular line—the heavy traffic. Before closing he would like to say that next year they would have their competition at Tunbridge Wells, where guests from Liverpool would receive as hearty a welcome as they had given to him. Being near to London and nearer to France they might expect more competitors, and that their French friends would be able to enter the competition and show what they could do.

Mr. A. L. Jones also responded. He said they should be proud of the distinct success of the motor-car in Liverpool on this occasion. Their chairman was the president of a society they were glad to see established, and they were proud to welcome him amongst them. There was, he thought, one thing he was more successful in than another, and that was in finding the man to do a thing better he could do it himself. What they wanted was a cheap means of transit to Manchester and Lancashire generally. It is the railway system here that had stifled the port of Liverpool, and that was the reason of his connection with the Self-Propelled Traffic Association. He was convinced that that Association would be the means of reducing the charges very materially, and if they could do that they would succeed in making the city and the district much more successful than it is at present. There was no doubt that the motor-car for heavy traffic—he did not propose to deal with the pleasure car at all—but for heavy traffic over a moderate distance, the motor-car offered advantages far in excess of anything the railway could do for them. It did not need any argument to show that in unloading a ship and loading a car to carry goods 15 miles or so in a short time much time and handling would be saved. They could have the car to take the load from the ship's side for any place within a reasonable distance. The cars shown in Liverpool had, he thought, the element of success, and he would be very much surprised if before long they did not see companies formed to work such cars. (Applause.) They wanted to be in the front, and they thought Liverpool was the finest port in the world, and as far as they were concerned with this little society they would do their best to add to the importance of the city. They appreciated the kindly interest taken by the Lord Mayor in the motors. As for Mr. Smith, the success of the undertaking was due to him. (Applause.) Once he got on the track he would never leave it until he got what he wanted. Then some of the most eminent engineers of the city had been good enough to give their time in the interests of the movement. He thoroughly appreciated the President's invitation to Tunbridge Wells, but he would rather welcome the President to Liverpool again. They wanted to centre this institution in Liverpool. They did not want to go to Chiswick, or any other place, for what was wanted. (Applause.)

Mr. Alfred Holt proposed "Our Guests." He said the great difficulty that had forced its attention upon those who were competing was the question of weight. In order to limit the weights they had been driven to extreme lightness of construction. If they could have 25 cwt. to the ton they would have been extremely glad. (Hear, hear.) With regard to their speed he hoped they would have every success, but he thought it possible that if the ingenuity that had been expended had been utilised on the road instead of the vehicle greater success would have attended it. The metal pathway would have done what the vehicle could not. He thought they should give their attention to the hardening of the roadway, easy curves, and gentle gradients, and they would diminish the cost of transit much more than by the means now proposed.

The toast was responded to by M. Giffard, M. Thirz, and Lieut.-Colonel H. W. Smith-Rewse, who, in acknowledging the toast, hoped that the motor-car would follow in the footsteps of their old friend the traction engine, which had proved its usefulness and pulled them out of many a difficulty. (Hear, hear.)

Professor H. S. Hele-Shaw proposed "Our Hon. Secretary, Mr. Shrapnell Smith." The speaker referred at length to the excellence of the work done by their hon. secretary, his untiring zeal for the work he had in hand, and said that the success of the trials was an evidence of the thoroughness with which he did his work. (Applause.)

Mr. E. Shrapnell Smith, in response, thanked all present for their appreciation of his work. He appealed for greater help. The membership at Liverpool was under 60, and they had made a lot of noise in Liverpool notwithstanding their income was only £60. He had been well helped by the Council, and they had made the most of their opportunities. They had succeeded better than he had hoped for, and he would look back upon this day with pride. He hoped the people of Liverpool would rally round them and give them greater support.

Mr. Barr proposed "The Technical Press," coupling with it the names of Mr. Stanley Spooner and Mr. Henry Sturmey.

The proceedings then terminated.

GEARING FOR AUTOMOTORS.

By Rhys Jenkins, M.I.M.E.

The devices for transmitting the motion of the motor to the driving wheels form a most important detail in the construction of a self-moving vehicle; they demand a considerable share of attention, and this indeed they have received at the hands of inventors during the past year or so, with the result that many very ingenious mechanisms have been produced, some of which have been noticed from time to time in the columns of The Automotor.

Among the most interesting of these schemes is that for hydraulic or fluid pressure transmission, that is to say, the prime mover is employed to actuate a set of pumps, which are in a closed circuit with a set of motor-cylinders on the driven axle. Now there can be no doubt as to the smoothness in working and the range and graduation of the speed ratio obtainable in this way, but one is tempted to believe that these advantages can only be obtained at too great a cost in regard to the complexity and weight of the mechanism, to say nothing of a comparatively low efficiency.

The remarkable speed-reducing properties of epicyclic trains have caused these mechanisms to receive the attention of a great many inventors. But here again it will no doubt be found that the advantages are more than neutralised by increased friction and wear and tear, particularly in those forms in which internal gearing is employed. The use of brakes in these gears for allowing a variable slip to what is usually the dead wheel certainly affords a convenient means for varying the speed, but such a practice is radically wrong, as the variation is obtained by expending the surplus power in friction, and converting it into heat in the underpart of the carriage. Still this idea seems to have attractions for a great many people.

The worm and wheel form another compact and simple means of reducing speed, and of late efforts have been made in several quarters to show that this mechanism is not so inefficient a transmitter as it is usually regarded, still it does not seem likely to come into extended use in motor-cars.

In spite of the great ingenuity which has been brought to bear upon the subject, there appears to be little doubt that old and well-known types of gearing which have approved themselves in general engineering practice, if carefully and skilfully applied, will give us the most satisfactory results, or at any rate will fully answer practical requirements.

The problem to be solved is the transmission of the power of a fast-running motor to the road wheels of the vehicle at a considerably reduced speed, and with the possibility of variation and reversal, and this in a situation exposed to considerable jar, to dust, and to atmospheric changes of no mean extent.

Although belt gearing and friction pulleys have been used with a certain amount of success, for constant and daily work the circumstances appear to demand positive action—that is to say, the use of either chain or spur gearing. Chain gearing gives the designer great liberty in disposing of the details of his car, and it has been applied with considerable success; and, in spite of its well-known defects, there can be little doubt that it will continue to be used, either in combination with spur gearing or alone. But wherever possible spur gearing should be relied upon—not, of course, that this form of gearing is without defects, but that, properly carried out, it will be found to give the most satisfactory results, consideration being had to constant and everyday use in all weathers and over roads of all qualities.

This conclusion is supported by the results arrived at in electric tramcar practice in the United States, in which by this time considerable experience has been gained. Belts, chains, worm gearing, bevel wheels, and spur gearing have all in turn been tried, but there is now no question of the superiority of the spur gearing. The motor is connected to the car axle by a pinion and spur wheel running in a bath of oil; the gears are machine cut and of steel, or the wheel may be of cast iron. A good deal of trouble was encountered at first on the score of noise, and raw hide pinions were extensively used, but the enclosure of the gearing in a casing which forms an oil chamber has permitted steel pinions to be used with manifest advantage.

Now, decidedly the gearing of a vehicle for ordinary roads is a far more difficult problem than is met with in the tramcar, where variations of speed have not to be provided for, and the size of the road wheels is such that an electromotor may conveniently be geared to their axle by a single wheel and pinion. Again, the gearing is not so much exposed to dust as is the case in the ordinary road carriage. Nevertheless, the experience gained with the simpler problem appears to indicate clearly the manner in which the more difficult case should be attacked.

In a motor-car an intermediate shaft between the motor and the driven axle would, as a general thing, be indispensable. Three speeds and a reverse would probably suit most requirements. To effect this the connection between two of the shafts must be made by four trains of gearing, which may be conveniently arranged two and two with the clutches between each pair. Such devices as sliding keys and the like are merely toys, and should be avoided. Electromagnetic or fluid pressure clutches lend themselves very readily to this application, and are very conveniently arranged for actuation, although indeed there need be no difficulty in this respect with ordinary clutches. The wheels should never be thrown out of gear with each other; it is too much to expect good results if it is attempted to throw the wheels into gear while in motion; they should be of steel with machine-cut teeth, and they should run in a closed casing forming an oil bath.

THE TESTING OF SECONDARY BATTERIES.

COMPARATIVE figures are often given, says an exchange, for different types of storage batteries, quite regardless of the rate of discharge per unit weight of plates at which they were working, which figures may be, and often are, very misleading, for if a curve be drawn for any given type of cell, plotting the pounds per kilowatt hour of the cell, over a base representing the rate of discharge in ampères, it will be found that a line passing through the successive values of pounds per kilowatt hours so plotted falls at first very rapidly, then more slowly, until at about 100 ampères it becomes a straight line, so that a fair comparison of two or more types of cells can only be made at the same rate of discharge per unit weight of plate in each case. Hence reports on tests of storage batteries, giving a comparison of two cells, the rates of discharge of which may be very different, should be corrected for such difference before being accepted as of any value whatever in so far as the comparison is concerned, for it is now well known that the capacity of an accumulator increases as the discharge current is reduced, the relation between the strength of the discharge current and the capacity being of the form

$$C^n \times T = \text{a constant},$$

C being the discharge current in ampères, and T the time of discharge in hours, the value of the exponent n being found by experiment with the particular type of cell, and ranges from 1·35 to 1·5.

Then, by the aid of the equation

$$C^n \times T = \text{a constant},$$

and knowing the capacity for a definite rate of discharge, its capacity at any other rate can be readily calculated. For if K denotes its capacity for a discharge current, C, and time of discharge, T, its capacity, k, for some other discharge current, c, and time of discharge, t, will be given by the formula,

$$k = K\left(\frac{C}{c}\right)^{n-1}.$$

THE ECONOMICAL USE OF STEAM IN NON-CONDENSING ENGINES.

IN America, says James B. Stanwood in the *Engineering Magazine*, the non-condensing engine is almost universally employed, especially in those districts where fuel is cheap and condensing water is dear. These conditions obtain over a very large portion of the country, particularly in cities and towns. Any improvement, therefore, in the economy of non-condensing engines benefits a large majority of American steam users.

Not very long ago, but before the days of Mr. Corliss, steam pressures of 40 to 60 lbs. were in vogue. Plain slide valves cutting off at about three-quarter stroke, or adjustable cut-offs by means of which more expansion was obtained, were generally employed. The speed of the engine was controlled by a butterfly valve operated by a fly-ball governor. The small mean effective pressure, in conjunction with a high pressure of steam at the end of each stroke of the piston (the terminal pressure) caused by a reduction of initial pressure and a low grade of expansion, was absurdly uneconomical. Mr. Corliss, by the invention of the automatic cut-off, radically changed these methods of steam distribution. Steam was admitted to the cylinder with as low initial pressure as 60 lbs., and, with nearly uniform loads, the size of the engine was proportioned so that the cut-off occurred at about one-quarter stroke, and the pressure at the end of the piston stroke was slightly in excess of atmospheric pressure. Under these conditions a maximum mean effective pressure was obtained with a low terminal. This satisfied the conditions existing in factories at that time—a probable dead load of nearly 50 per cent.

Observe what would have been the result if these engines had been required to operate for long intervals with one-third or one-quarter load; the cut-off would have been automatically adjusted to one-eighth or one-tenth of the stroke, and with 60 lbs. of steam the degree of expansion would have been so great that the terminal pressure at the end of the piston stroke would have been 5 lbs. or 6 lbs. below atmospheric pressure, reversing the pressure on the piston and causing it to drag like a pump. At the same time the mean effective pressure would have been as low as 8 lbs. or 10 lbs. —far too small for economical operation.

This high degree of expansion sometimes occurred in Mr. Corliss's practice, especially where engines too large for the work required were installed; builder and user were sorely disappointed at the resultant waste, and were at a loss to account for it. It was easily seen that the drag of the piston, due to expansion below the atmosphere at the end of the stroke, accounted for part of it. But should not this have been offset by the high degree of expansion?

With recent developments in electricity a steam-engine driving a generator is the ordinary instrument for deriving energy from coal. In this application light loads and variable loads form a greater proportion of the engine's duty than formerly. For instance, in most factories with mechanical transmission a large portion of the power given out by the engine has gone to drive the transmission machinery

—that is, gearing, shafting, pulleys, and belts. This dead load frequently consumes one-third to two-thirds of the entire power. An engine in such a factory always has a large minimum load. When electrical transmission is employed, the transmission load appears only when work is being done at the motor or lamp, so that the minimum load on the engine is only that due to its own friction, together with the resistance of the generator—usually, in all, not more than 20 per cent. of the rated capacity of the engine. It is seen, therefore, that with electrical transmission the fluctuations in load between maximum and minimum are much greater than with mechanical transmission. On account of a high degree of expansion developed by this prevalence of light loads in this field, it has not been possible to operate engines economically.

Experience has shown that there is a limit to the degree of economical expansion, and this limit has been found to vary with different types of engines. Long-stroke engines were found to have a greater limit, and to be more economical, than short-stroke engines; short-stroke engines at high speed were more economical than short-stroke engines at slow speed; engines with short clearance spaces (the waste space between the piston head and cylinder head at end of stroke, including the steam ports) were more economical than those with large clearance spaces. In long-stroke engines the most economical degree of expansion was found to be about four; in some short-stroke engines it was as low as two. That is to say, in long-stroke engines the economical cut-off should take effect not earlier than one-fifth of the stroke, and in some short-stroke engines not earlier than one-third. Experimental investigations have shown the reasons for this limitation of expansion; practice and experience have devised methods of extending the limit.

Two serious losses develop with high expansion produced by early cut-offs in single-cylinder engines. The first and most easily discerned is known as the "clearance loss"; the second and more subtle is the "cylinder condensation loss." It is obvious that, if the clearance spaces have to be filled at each stroke with fresh steam from the boiler, there is a distinct loss, since this steam is thrown away without doing much work. Clearance space in long-stroke engines is ordinarily 3 or 4 per cent., though it has been reduced to about 1 per cent. in special cases. In some short-stroke engines the clearance is 15 or 16 per cent. This accounts for one advantage of long-stroke over short-stroke engines. Wherever clearance spaces are large, they can be partially filled by compressing into them some of the steam left in the cylinder during exhaust; but, as a rule, they give poor economy, as this gain by compression is only slight.

The "cylinder condensation loss," the largest of all the losses, is not generally understood by steam users themselves, although clearly recognised by intelligent engine builders and engineers. The laws which govern it have not been fully ascertained quantitatively, although the manner in which they vary is fairly well understood.

What is this loss?

At each stroke that any engine makes, fresh steam from the boiler meets the surfaces of the steam passages, cylinder head, and piston head, and the cylindrical walls of the cylinder up to cut-off, all of which have previously been cooled by exposure to the low temperature of exhaust steam, and by the abstraction of heat during the period of expansion. These cool surfaces have to be reheated by fresh boiler steam in order that the cylinder may be habitable for that portion which is to do work. A certain part of this fresh steam is thereby condensed, and becomes a loss, which is called the "cylinder condensation loss."

This amount of cylinder condensation seems to depend upon the amount of condensing surface exposed up to the point that cut-off takes place; upon the difference in temperature between fresh in-coming steam and out-going exhaust steam (known as the range of temperature); upon the time which these surfaces have for cooling and reheating (this is regulated by the speed of the engine); and upon the degree of expansion which takes place in the cylinder. The nature of the surfaces, whether smooth or rough, likewise has influence on the amount of condensation. It is difficult in any engine to forecast exactly the amount of cylinder condensation, but in any given engine it appears to be nearly constant at all points of cut-off at any given speed, boiler pressure, and exhaust pressure.

Under these conditions the "cylinder condensation loss" acts very much like a large clearance loss. It is least in long-stroke engines, as they offer less surface for condensation, per volume of steam used; it is most in short-stroke engines, for the opposite reason. High-speed short-stroke engines are an improvement upon slower short-stroke engines, as the time for condensation is less. In an ordinary long-stroke Corliss engine, working with either early or late cut-off, about 7½ per cent. of a volume of steam equal to the cylinder-full at boiler pressure is condensed to keep the cylinder hot. If 2 per cent. of the steam is thrown away as a clearance loss and 7½ per cent. as a cylinder condensation loss, the total loss is 9½ per cent. This loss is relatively much larger when steam is admitted for only one-sixth or one-fourth stroke than when it follows the piston for one-third or two-thirds stroke. Therefore the losses, together with the drag of piston on account of expansion below the atmosphere, are much greater with early cut-offs than with late, and the economical limit to expansion is reached when the gain due to expansion is neutralised by this increasing loss of clearance and cylinder condensation and "drag." It is thus easily seen that large engines with light loads, or engines which work under great variation of loads, must operate at early cut-off, and under three very disadvantageous conditions—to wit, with heavy clearance loss, with cylinder condensation losses, and with a positive resistance developed in the cylinder by the dragging of the piston against atmospheric pressure.

Since the days of Mr. Corliss, steam pressures have continued to increase; this increase of pressure has intensified, in single-cylinder engines, clearance and cylinder-condensation losses. The absolute clearance loss is increased, because the clearance spaces have to be filled by steam at higher pressure, which weighs more per cubic foot than steam at lower pressure. The absolute cylinder condensation loss is increased, because the difference in temperature between fresh incoming steam and outgoing exhaust steam (range of temperature) is increased. For example, the temperature of steam at 60 lbs. pressure is 307° F., while the temperature of steam at atmospheric pressure, at which it exhausts, is 212° F.—a difference of 95° F. The temperature of steam at 100 lbs. pressure is 338° F., making a difference of 126° F.; and this increase of temperature-range condenses a greater amount of fresh boiler steam (which is another way of stating that cylinder condensation is increased).

The increase of pressure, however, has reduced the loss due to the dragging of the piston against atmospheric pressure in single-cylinder engines. With a given maximum cut-off the ratio between the minimum mean effective pressure (that can be secured without expansion below the atmosphere) and the maximum mean effective pressure becomes greater, so that a lighter load in proportion to maximum load can be carried than with lower boiler pressure.

The clearance and condensation losses tend to prevent a gain in economy with high-pressure steam. To secure this gain, which was theoretically possible, engineers were compelled to abandon the plan of using steam in one cylinder only, experience having proved that higher degrees of expansion with less loss can be secured by expansion through two or more cylinders. A knowledge of these facts was obtained by experience in marine practice, where many practical advantages were secured, besides economy of fuel by the use of multi-cylinder expansion engines.

The success in this field of engineering naturally attracted the attention of steam users and builders of stationary engines. Manufacturers of automatic cut off engines began to compound their engines. When condensers were employed with these newly-arranged engines, a very satisfactory saving was effected, but, when these engines were built for non-condensing service, the result was a positive failure, except in a few rare instances, where the load was nearly constant and the engine properly proportioned and designed for that load.

Unless the amount of power required is so great, and the change in the load so gradual, that a number of units can always be kept in service with nearly a full load upon each unit, the compound-non-condensing automatic cut-off engine is ill-adapted for electrical plants in which there is a great variation between light and full load.

The conditions that have caused the failure of this type of engine under varying loads are the same that have caused the failure of single-cylinder automatic cut-off engines similarly loaded. Before considering them, it is well to state the different methods of distributing steam in these compound engines. There are two distinct methods of distribution: first, where the valve or valves of the high-pressure cylinder are under control of the governor; second, where the valve or valves of both cylinders are under control of the governor. Another dual classification can be made by grouping those engines in which the admission valves are under control of the governor, and those in which both admission and exhaust valves are under this control.

With light loads, the loss due to expansion below the atmosphere is greater than in simple engines, as this loss develops in the low-pressure cylinder, which has a large area and gives a great resistance. Frequently the low-pressure cylinder is converted into a pump, which has to be dragged along by the high-pressure cylinder. As boiler pressures increase, this difficulty is not lessened, because the minimum mean effective pressure that can be obtained without expansion below the atmospheric line increases with the boiler pressure, and at about the same rate as the maximum mean effective pressure, so that the ratio of minimum to maximum mean effective pressure is not reduced for light and heavy loads, as is the case in simple engines. In engines in which valves of both cylinders are under control of the governor, this drag develops in the high-pressure cylinder whenever its terminal pressure falls below the high receiver pressure induced by early cut-off on the low-pressure cylinder.

When the governor controls both the steam and exhaust valves on both cylinders, and the load is light, it is necessary to employ enormously large clearance spaces, into which the steam imprisoned by early compression can be compressed without overstraining the engine. The effect of these large clearance spaces is to maintain a very high terminal pressure in each cylinder, which, with light loads, greatly reduces the chance for the "drag," but, with heavy loads, greatly increases the loss from clearance. In fact, these engines operate with only moderate degrees of expansion, considering the neutralising effect of their large clearance.

By proper treatment of compression, clearance losses can be greatly reduced in compound engines. This is the case in engines in which the governor controls only the admission valves of both cylinders. By proper adjustment of these valves the receiver pressure can be kept nearly constant; with small clearance spaces and a fixed compression, the clearance losses can be kept very small, and become excessive only with very early cut-offs. But, in an engine in which the governor controls the valves of the high-pressure cylinder only, this loss is greatly augmented at light loads, because the high degree of expansion caused by an early cut-off gives a low receiver pressure, and the clearance spaces have to be filled at every stroke with a low back pressure by steam at boiler pressure.

The chief economical advantage of compounding is to reduce the cylinder condensation loss. We have already seen that the difference in temperature between 100 lbs. steam pressure and atmospheric pressure is 126° F. This difference amounts to 154° for 150 lbs. pressure, and 169° for 200 lbs. pressure. By expanding steam through two or more cylinders, this temperature range can be reduced to ½, ⅓, &c., according to the number of cylinders used, provided, however, that the expansion is properly divided in each cylinder. By reducing this temperature range a great reduction can be effected in the cylinder condensation loss.

We have seen that cylinder condensation in a simple engine is proportionately less at a late cut-off than at an early cut-off. This holds true in compound engines; but, whereas, in the simple engine, the late cut-off is uneconomical on account of the low degree of expansion, it becomes economical in the compound engine, as a high degree of expansion is obtained, and at the same time it is unhampered by excessive cylinder condensation.

Under these considerations it can be seen that in an engine in which the steam distribution is controlled by varying the cut-off, and in which light loads are developed by means of early cut-off, it must follow that these early cut-offs induce increase of cylinder condensation losses (and clearance losses), and in that way completely neutralise the object of the compounding.

These are the reasons which render compound non-condensing automatic cut-off engines a failure for variable loads. They can be successfully employed, as we have stated before, only when the load is uniform and the engine properly proportioned for that load.

The mistake of engineers and designers is in assuming that the average automatic expansion gears upon which they have bestowed so much care and attention are suitable for the proper distribution of steam in a non-condensing compound engine. Some of these gears may possess superior advantages for regulation and high speeds, but their advocacy stands in the way of economy and intelligent development of the steam-engine. With their use higher pressures cannot be employed, and they are unsuitable for the more moderate pressures now in vogue.

From the foregoing it appears that automatic expansion gears applied to non-condensing compound engines are inadequate for the proper distribution of steam for varying loads. Mr. Charles T. Porter, the celebrated American engineer, in a paper presented to the American Society of Mechanical Engineers in 1894, said:—"It is clear that, if the variable cut-off had not been already in common use, nothing so unsuitable would have been devised for this purpose." He also said:—"It has appeared to me that an opening presented itself for a large improvement in the direction of economy, by employing a fixed point of cut-off, suitably selected, and regulating by means of a throttling governor."

The writer believes that, where the load is variable, the employment of a throttling governor with a fixed point of cut-off as a method of distributing steam in non-condensing multi-cylinder engines will lead to a satisfactory solution of this rather intricate problem.

In another paper the advantages and disadvantages of such a system of distribution will be set forth. Here it is necessary to state only that this system has been extensively developed in connection with vertical engines in England, directly connected to bi-polar electric generators, and operated at speeds as great as 400 or 500 revolutions per minute. The success of the system is largely due to the efforts of the late Mr. Willans, who was led, after years of experimenting, to select the throttle as an instrument by which to control the well-known high-speed engine bearing his name.

THE MERITS OF THE DIESEL MOTOR.

THE following is taken from the paper presented by Mr. Aimé Witz to the Academy of Science, on the Diesel engine. As several of our readers wish us to publish this paper in its entirety, we comply with their request:—

The cycle of "internal combustion engines" consists of four distinct phases of operation, which are easily described. It begins with adiabatic compression from the atmospheric pressure H until a pressure π, having for its object to raise the temperature of the explosive mixture from t to θ. The second phase consists of a combustion at constant pressure under the same pressure π, during which phase the temperature passes from θ to T; the heat supplied by the stove (source of heat) being equal to $C(T-\theta)$, C being the specific heat of gas under constant pressure. It proceeds then with adiabatic expansion, which brings back the burnt gases to atmospheric pressure, and their temperature to t'. Finally the cycle becomes closed with a renewal of heat which makes the gases contract and re-establishes the initial conditions of temperature and pressure; the removed heat equals $C(t'-t)$ since this latter operation is effected under constant pressure of the atmosphere. Thus the cycle is described by two adiabatic curves and two straight lines parallel to the axes of the volumes.

The efficiency is easily calculated—

$$\rho = \frac{C(T-\theta) - C(t'-t)}{C(T-\theta)} = 1 - \frac{t'-t}{T-\theta}$$

The adiabatic transformations give us—

$$\frac{t}{\theta} = \left(\frac{H}{\pi}\right)^{\frac{\gamma-1}{\gamma}} \text{ and } \frac{t'}{T} = \left(\frac{H}{\pi}\right)^{\frac{\gamma-1}{\gamma}}$$

whence—

$$\frac{t}{\theta} = \frac{t'}{T} = \frac{t'-t}{T-\theta}$$

therefore—

$$\rho = 1 - \frac{t}{\theta}.$$

A Carnot cycle would have given a superior efficiency equal to $1 - \frac{t}{T}$; our cycle has therefore a generic efficiency smaller than the the unit. But at the utmost, this efficiency could have been reached if t had been equal to θ; it is true that then the work would have tended towards zero. The classic cycle of Joule has the same peculiar quality. The work developed grows with the removing of T and θ, but the efficiency of the cycle is independent of the values of T. We see, therefore, that the absolute efficiency remains the same, whatever the work may be; in other words, *the efficiency is the same at full and half load*, a peculiar and valuable property, to which great value is attached.

The power of a motor working on the lines of this cycle would be practically governed by the duration of the combustion and the amount of heat transferred during the first phase of the cycle, which is to say, by the removal of T and θ. Such a motor could have small dimensions, seeing that the area of the cycle is considerable and much larger than that of "explosion" engines; the smoothness of running would be remarkable, seeing that the pressure remains constant during the whole of admission.

It is the value of θ, and consequently the degree of compression, which govern the efficiency of this cycle.

Or let us assume that we could compress the mixture to 250 atmospheres (3,750 lbs. per square inch), when we would have:—

$$\theta = t\ (250)^{0.23} = t\ 3\cdot56$$

and

$$\rho = 1 - \frac{1}{3\cdot56} = 0\cdot719.$$

This extraordinary efficiency is the triumph of "high preliminary compression"; there is no other cause for it.

But one might be contented with a smaller degree of compression; if we assume, say, 35 atmospheres (525 lbs. per square inch), we still find ρ to be something like 0·557.

This is a figure to which the theory would have scarcely accustomed us, and which is much superior to the "efficiency" of the most brilliant steam-engine. The Diesel engine itself, the value of which has been so much exaggerated, does not give a theoretical efficiency superior to the efficiency of such "internal combustion engines of high compression" which we have just above calculated.

The compression of 250 atmospheres (3,750 lbs.) is that of which the German scientific engineer dreamt, that of 35 atmospheres (525 lbs.), is that which he had the rare merit to realise; applied to the classic cycle of "internal combustion engines," they would produce the same miracles as the Diesel engine.

The "internal combustion engine," besides, has the same good features as the new motor, from the point of view of power, elasticity, smallness of dimensions, &c.

Its cycle has even itself a superior advantage, that is, that it can be easily realised, and that it is not perceptibly deformed when one passes from theory to the application of the theory.

The Gardie engine has proved the latter fact. It is, therefore, in the high compression which Mr. Diesel has succeeded in rendering applicable in his engine that one must seek for the cause of the obtained good results.

With respect to the forogoing criticism, we may say that we think there is more than a "practical" evolution to be noticed in this interesting motor.

It has to be borne in mind that in an ordinary gas or oil engine fuel and air are being compressed by the piston on the compression stroke, whilst in the Diesel engine this compression only *affects the air* which, when thereby compressed, meets the fuel, ignites it by the compression heat and *not by external means*; then follows an almost isothermal expansion, since there is almost a constant and slow combustion taking place.

THE PRONY AND PONCELET.

By M. Hospitalier. (From *La Locomotion Automobile*.)

In 1889 the International Congress of Mechanism, held in Paris, at the Conservatoire des Arts et Metiers at the Universal Exhibition, adopted the poncelet of 100 kilogrammetres per second as the industrial unit of power. In spite of the advantages of this metric and decimal unit (of almost the identical size of the electrician's kilowatt), manufacturers continue to make use of a steam H.P. of 75 kilogrammetres per second, a purely empirical unit, obviously copied from the English H.P. so called, in order to be hidden among other English units in a future which, we hope, is near at hand.

Habit and routine, the sloth of intellect, are not the only reasons why the poncelet has met with a rather chilling reception from manufacturers; its chief fault is its being too large for sale. A motor of 4 H.P. is only 3 poncelets, and that suffices in our day, so proud of its civilisation, to kill the most legitimate reform. Grocers sell in pounds (demi-kilogramme) because the published sum is twice as little as if the unit of weight was a kilogramme. The crevettes actually sell at 2 francs the 125 grammes, and the price appears more accessible than if quoted at 16 francs the kilogramme. Electrical energy is sold at 10 centimes per kilowatt per hour—cheaper than gas; if it was tariffed at 1 franc per kilowatt per hour, it would appear to cost more than gas. The standard of light established by M. Violle in 1884 has not been adopted by anyone. The idea of taking as a practical unit (under the name of the "bougie decimale") the twentieth part of the Violle unit was mooted in 1889, and since then all the sellers of light have adopted the bougie decimal.

All our recriminations will serve for nothing, and we will struggle in vain against these relics of barbarism if we cannot profit by the suggestion of employing, in the cycle and automobile industries, a new unit of power of which we are about to show the advantages.

The kilogrammetre per second is too long a name and too small in size; steam H.P. or H.P. of 75 kilogrammetres per second is absurd, as it is neither in the metric system nor in the decimal; the poncelet of 100 kilogrammetres per second is too long. We propose an intermediary unit, the prony of 10 kilogrammetres per second, about the tenth of a poncelet in value, and perceptibly equal to the hectowatt of electricians.

The name "prony" calls to mind that of the inventor of the brake used partly by the power produced by the motors, and we do not know of a better and more appropriate name. The prony very perceptibly represents the power of a man of medium strength operating the pedals. The prony is worth exactly 98·1 watts, or practically 100 watts or 1 hectowatt, which facilitates the transmutation of the results of metric and electrical international units. The prony suppresses ordinary fractions in the designing of motors used for cycles and automobiles. The numbers explaining the power of the automobile motors are generally between 1 and 200, that is to say, very easily handled.

Lastly, an important consideration for engineers, the use of the prony considerably simplifies calculations of the power necessary for the propulsion of a vehicle.

Let P be the power in pronys.
F be the weight of the vehicle in tons.
k be the coefficient of traction in centimes; tan a the gradient in centimes.
v be the speed in metres per second.

Then—

$$P = F\ (k + \text{Tan}\ a)\ v \text{ (pronys).}$$

Example.—A vehicle weighing 1,500 kilogrammes is required to ascend a gradient of 2 per cent. at a speed of 4 metres per second; the coefficient of traction being 3 per cent.

The power necessary to apply to the periphery of the wheel will be:—

$$P = 1\cdot5\ (3 \times 2)\ 4 = 30 \text{ pronys.}$$

If the efficiency of the system is 80 per cent. the power of the motor to give the speed must be:—

$$P' = \frac{30}{\cdot8} = 37\cdot5 \text{ pronys.}$$

If an electric motor is in question it should furnish 37 hectowatts or 3,700 watts. By this example one can see how calculations can be simplified, as the formula we have pointed out does not draw out any superfluous factor to complicate calculations.

Now that the horse is so rapidly losing its importance as motive power it is reasonable to search for a substitute for him by creating a unit more suitable for the actual requirements of the cycle and automobile industries. The prony, such as we have pointed out, seems to us to fill the greater number of the required conditions, and it is with confidence that we submit it to the examination and criticism of our colleagues, and only await more powerful votes in proposing its adoption—or rejection.

The Storage of Petroleum in the Lancashire District.—The correspondent of *The Engineer* at Manchester writes to his paper to the effect that ample provision is being made for developing an important oil trade on the Manchester Ship Canal, large storage tanks having been erected at Mode Wheel by the Manchester Corporation, the Liverpool Storage Company, and Messrs. Bagnall; whilst at Eccles, on the opposite side of the canal, the Anglo-Caucasian Oil Company is erecting large tanks. These four depôts for the storage of oil will cover upwards of 20 acres of ground, and the output for which the Manchester Corporation and the companies already referred to have made arrangements seems to point to a traffic of considerably over 100,000 tons a year. The appliances in connection with the tanks are exceedingly simple and complete, all risk being reduced considerably below the average, and at all the tanks the oil is pumped direct from the tank steamers that come up the canal. As a further provision of safety, the whole of the oil trade will be dealt with below the Mode Wheel Locks, and no ship carrying oil in bulk will at any time enter the Manchester Docks. Other important work at Mode Wheel is a doubling of the sidings' capacity, to meet the requirements of the rapidly growing trade by extending the gridiron, which has now storage for 500 wagons.

THE AUTOMOBILE CLUB OF GREAT BRITAIN.

The following account of the second tour of the Automobile Club of Great Britain has been contributed by a member:—

On Friday, May 27th, there was not a great show of motor-vehicles outside the Club for the start of the Whitsuntide tour, for the reason that several machines were to join us *en route*. However, there were present:—

(a) The Club Wagonette No. I (kindly lent by the Daimler Motor Company) with Mr. E. Instone (as driver), Sir J. R. Somers Vine, C.M.G., Mr. Louis d'Egville, and Mr. Thos. Neale (of New South Wales), as passengers. This Wyley carriage ran splendidly throughout, and was driven most admirably by Mr. Instone, who shows skill and judgment, and avoids the reckless scattering of crowds and general bad form which go so far to check popular admiration for motor-carriages and their patrons.

(b) The Club Wagonette No. II (also lent by the Daimler Motor Company) driven by one of the Company's drivers, who, although very skilful, has a good deal to learn from Mr. Instone as to the proper speeds to use under varying circumstances. The passengers on this wagonette were Mr. R. Phillips, Mr. A. Boult, Mr. C. Cordingley, and Mr. C. G. Harper. The carriage ran without a hitch throughout.

(c) Club Wagonette No. III (the property of the Brighton Motor Company, and driven by their driver, Holland, an experienced and reliable man).—The passengers were Mr. C. K. Townsend, Major Howey (as far as Saxmundham), Mr. Holland Tringham, and the Secretary, Mr. C. Johnson. This wagonette was one of the two first machines built by the Daimler Company. It has run some 5,000 miles, and, except that it wore its india-rubber tyres through and required new ones, it has until now undergone no serious repair. But machinery will not run for ever without renewal. Parts on which there is friction or strain must be replaced from time to time, otherwise disaster must ensue. And in this case disaster resulted, for at Woodbridge a part gave and the old wagonette was left in that horse-loving town while its passengers were taken on in other carriages.

(d) Mr. P. Drummond and Mrs. P. Drummond, of Stirling, were on a Daimler Wyley carriage constructed by Messrs. T. C. Stirling, of Hamilton, N.B., and driven by a Scotch driver, Muir, by name, a thoroughly trustworthy Jehu. This carriage ran perfectly throughout.

(e) Mr. Estcourt (with Mrs. Estcourt and Mr. and Mrs. Michael as passengers) drove his own Daimler carriage. Since he had the holes in the exhaust silencer opened out, Mr. Estcourt has found this carriage has gone far better. It ran well throughout the tour.

(f) Mr. Frederick R. Simms (Vice-Chairman) was driving the Hon. Evelyn Ellis's Daimler with Mr. Harrington Moore (the Hon. Secretary), Mr. Lane, and Mr. Hankinson on board. Except for a broken valve, which caused an hour's delay, this machine ran excellently.

(g) Mr. Cecil Grimshawe joined the tour a short distance out of London on his very smart Daimler sporting car, and ran throughout the tour in most excellent style. No carriage in the Club is better kept or does more credit to the Club than Mr. Grimshawe's. Mr. Grimshawe had as passengers Mr. Elim and his servant.

(h) Mr. Frank Butler (the Hon. Treasurer) started from London late but overtook the party at Hertford. His pretty little Benz $2\frac{8}{10}$ H.P. ran well throughout except for the loss of a part which caused two hours' delay outside Norwich.

(j) Mr. H. Hewetson's $2\frac{8}{10}$ H.P. Benz also did well throughout the tour, except that it was refractory on the journey between Bury St. Edmunds and Norwich. It recovered its character by running from Colchester direct to London on Tuesday, after 4 p.m.

(k) Major-General E. L. England, C.B., ran throughout the tour on his De Dion tricycle, and was usually first to arrive in every town. General England evidently thoroughly understands his machine and treats it well.

(l) Mr. E. Townsend drove a Bollée all through the tour. Mr. Parker, his passenger, is no light weight, but for all that the Bollée went well, and pleased the eye, but certainly not the ear.

(m) The "Lifu" steam luggage van (kindly lent by the Liquid Fuel Company) carried an enormous quantity of baggage throughout the tour, and gave perfect satisfaction.

The 12 vehicles which started with the intention of completing the whole journey of 330 miles have now been dealt with, and it will be seen that all accomplished the distance except one (c).

In addition to the foregoing were:—

(n) Mr. Stopes, who ran on his Benz from his home at Colchester to Norwich and back.

(o) Mr. A. Mulliner (Daimler), who, with Mrs. Mulliner, ran from Northampton and joined the party at Cambridge, leaving it for the north again at Norwich.

(p) The Earl of Shrewsbury and Talbot, who, on his French Daimler, ran as far as Barnet to give the tour a "send off," and returned from there to keep engagements in London.

(q) Mr. Parr on the Headland's Electric Phaeton took Mr. Eyre and his son a short run to see the tour leave London.

(r) Mr. Crampton, on a De Dion, with the Club from Cambridge to Colchester.

(s) Mr. Egerton, on a De Dion, from Newmarket to Saxmundham.

Mr. R. E. Crompton and Mr. Blount rode throughout the tour on bicycles.

Mr. Worby Beaumont joined at Royston, and rode on a bicycle for the remainder of the journey.

The distances covered daily were 62¾, 68¼, 62, 54¾, 40, and 35½ miles respectively.

At Cambridge, Professor Ewing, the University Professor of Mechanics, presided at the Club dinner, and Mr. Oscar Browning (History Lecturer), the Hon. C. S. Rolls, and others, were present as guests of the Club. Professor Ewing rode out to meet the Club vehicles, and was seen timing their speed. In his after-dinner speech he congratulated Mr. Simms on the foundation of a Club which is doing a very useful work by encouraging interest in this new mode of locomotion. He added that he believed that the greatest development of the movement would be in the direction of goods traffic, and that the motor-vehicle would lead in some degree to the solution of one of the great social problems of the time, namely, relieving the congestion of towns by bringing back people into the country.

There was a big gathering of undergraduates to see the departure of the Club on the Saturday morning. The Committee arranged for some of last year's University crew to have seats as far as Newmarket, and took under their special protection Mr. Etherington Smith, the president of the University Boat Club.

These tours are taken very seriously by the Club Committee, who look upon them not only as pleasure trips, but as crusades against prejudice and ignorance, and as the means of proselytising amongst those who do not understand or appreciate the motor.

For instance, at Norwich, Mr. Roger Wallace, Q.C., the chairman, who had attended the Liverpool trials, joined the party, and at the Club dinner there on the Saturday night there were present as guests:—Mr. Deuchar (who presided); the Mayor of Norwich (Mr. Rix Spelman); the Deputy-Mayor (Sir Charles Gilman); Sir Harry Bullard, M.P.; Colonel, Mrs., and Miss Wood (Colonel Wood recently commanded the district); Baron Küssel; Colonel Dawson; and others.

On Whit Sunday Mr. Deuchar and Baron Küssel drove in Mr. Drummond's Daimler to Wroxham and back, and expressed themselves as being delighted with their first experience of "motoring," and on the Monday Mrs. Wood and her two daughters accepted an invitation to accompany the Club a "little way" on the road to Ipswich, and ended by journeying in motor-carriages 34 miles before luncheon. This is the proselytism carried out by this vigourous young Club. Wherever they go they make new friends for the movement. The Ipswich and Chelmsford newspapers give descriptions of their editors' first experiences in motoring. A photograph taken at Norwich shows the "turn out" of vehicles there assembled, viz., nine Daimlers, one Benz (two were out rambling), one Bollée, and four De Dion tricycles.

At Colchester Mr. Stopes (a member) entertained the party at luncheon, and Mr. Crompton (who took the chair on his birthday at the Club dinner at Chelmsford, and who was accorded a great reception by his fellow-members) showed the members over his firm's electric works.

All the members taking part in the tour expressed themselves as being delighted with it. The members have been summoned to attend a meeting on Wednesday, the 15th inst., at 8.30, to consider proposals for further tours, runs, &c., one of the suggested tours for August being the route described in William Black's "Strange Adventures of a Phaeton." This journey would split up well into nine days' travelling of an average of 50 miles a day, as follows:—

	Miles.
(1) London *viâ* Henley to Oxford	58¼
(2) Oxford *viâ* Woodstock to Worcester ..	56¼
(3) Worcester *viâ* Kidderminster to Shrewsbury	47¼
(4) Shrewsbury *viâ* Chester to Liverpool ..	56½
(5) Liverpool *viâ* Preston to Lancaster	52¼
(6) Lancaster *viâ* Kendal and Windermere to Keswick	51½
(7) Keswick *viâ* Penrith to Carlisle	37
(8) Carlisle *viâ* Gretna and Lockerbie to Moffat	40¼
(9) Moffat *viâ* Annandale to Edinburgh.. ..	52
Total	452

Monsieur le Baron de Zuylen de Nyevelt, the President of the Automobile Club de France, has written to Mr. Frederick R. Simms, the Vice-Chairman of the Automobile Club of Great Britain, stating that he will with pleasure place at the disposal of members of the Automobile Club of Great Britain cards of invitation, provided that, in order to comply with the rules, the Chairman of the Automobile Club of Great Britain supplies a list signed by him of members desiring to frequent the Club.

The following members have already notified their intention to leave London on Friday, the 17th instant, to visit in Paris the Exhibition of the Automobile Club de France:—Messrs. Frederick R. Simms (Vice-Chairman), Frank Butler (Hon. Treasurer), C. Harrington Moore (Hon. Secretary), Hon. Cecil Duncombe, Boverton Redwood, and W. Worby Beaumont (Members of the Committee), Drummond, Edge, White, A. Mulliner, A. Bird, B. Blount, Twist, Redfern, and the Secretary. Mr. Roger Wallace, Q.C. (Chairman), will also visit Paris during the course of the Exhibition.

It is proposed to run a Club motor-carriage from the Automobile Club of Great Britain to Ascot on the "Cup" day, and, if not too late in applying for space, an enclosure for the accommodation of members of the Club and their motor-carriages will probably be secured on Henley racecourse during the regatta.

The Spa Concours.—In response to the following invitation, addressed to the President of the Automobile Club, it is proposed that a party of members should leave London for Brussels and Spa on Friday, June 24th:—

To the President of the
Automobile Club of Great Britain.

The Automobile Club of Belgium begs you to invite in its name the members of your Club to assist at the competitions which it is organising at Spa, from June 25th to 30th, and Sunday, July 3rd next, competitions which will commence by the Brussels-Ardenne-Spa Race (June 25th to 26th).

We hope, Mr. President, that members of your Club will do us the honour to assist at, and even take part in, our competitions.

Comte F. de Villegas de Saint-Pierre,
Secretary General.
Comte F. van der Straten-Ponthoz,
President.

Since our May issue was published, the Automobile Club has been making steady progress. In addition to the very successful Whitsuntide tour, which we give an account of above, amongst the new members elected are:—Major H. C. L. Holden, R.A., F.R.S. (Army and Army Club), Major E. W. Howey (East India United Service Club), Messrs. Hugh Wequelin (St. James's and Bachelor's Clubs), Louis d'Egville (Sports Club), J. F. Medina (Automobile Club de France and City of London Club), F. M. Gowan (late North Staffordshire Regiment and Hurlingham Club), J. G. Lorrain (Whitehall Club), H. A. Mavor (Whitehall Club), Alfred Mavor (Whitehall Club), Sydney Tebutt (Royal Yacht Club, Southampton), Edmund Howl (of Derby), John Waddington (of Frant), J. H. Greenhill (Whitehall Club and Royal Ulster Yacht Club), S. H. Terry (Whitehall Club), A. Thompson (Royal Temple Yacht Club), J. M. Gorham (Whitehall Club), D. H. Halpin (Whitehall and Constitutional Clubs), B. Blount (Whitehall and St. Stephen's Clubs), J. Munton Jaffray, J.P. (Raleigh, Baths, &c., Clubs), J. F. Albright (Whitehall Club), H. Heatley (Constitutional Club), A. G. Hermann (Automobile Club of Vienna), &c., &c.

On May 24th Mr. Frederick R. Simms was appointed a Vice-Chairman, and Mr. Frank Butler was appointed Honorary Treasurer of the Club.

The Secretary of the Club notifies us that 300 members having been elected, the Roll of Founder Members is complete, and, in accordance with Rules 40 and 41, only applications for election as an Ordinary Member (annual subscription £3 3*s*., entrance fee £1 1*s*.) or as a Life Member (*i.e.*, a subscriber of not less than £25, who is thus exempt from entrance fee and annual subscription) can now be entertained.

The following further communications have been received by the Secretary of the Automobile Club of Great Britain in respect of the Customs duty upon motor-vehicles entering the various countries temporarily:—

Germany.

Sir,—In reply to your letter of the 26th ultimo, I am instructed by H.M.'s Ambassador to state that from inquiries made on the subject of the duty-free admittance of private motor-vehicles for pleasure purposes and for a limited period only, I am informed that in all probability the said vehicles would be admitted free of all charge at the Custom-house of entry (under paragraph 5, section 5, of the Customs Tariff Law of 1879-85), on a guarantee being there given to the authorities that they are only introduced for travelling purposes, and not for sale.

But in any case, if this were not allowed by the particular Custom-house of entry, it would only be necessary to deposit the amount of the duty that might be fixed, which would then be repaid at whatever place the vehicle again crossed the frontier. This duty would probably be that under No. 15B, and of the Tariff of 8*s*. per 100 kilogrammes (for locomotives), or that under No. 15, c. 2, of £7 10*s*. for a whole vehicle or conveyance.

It is not possible for the Central Customs Authorities of Berlin to take measures to provide beforehand for a free entry all over the Empire, as the Custom-houses of the different States of the "Customs Union" are still, to a certain extent, independent, and the question of a duty-free admittance might be differently viewed and treated in them.

It might be possible to ascertain the exact duty by writing direct to the authorities of whichever Custom-house at which it is proposed to enter the motor-car, under the provisions of a new law only in force since April 1st of this year, and of which I enclose a translation for your guidance.

I am, Sir, your obedient servant,
W. S. H. Gaskell, *Coml. Attaché to Embassy.*

Berlin, *May 10th*, 1898.

Italy.

To the President of the
Automobile Club of Great Britain, London.

You express a wish that the automotors for the members of the Club should be admitted free of all frontier duty when they are introduced temporarily into the kingdom. I hasten to inform you that it is impossible to accede to this request; moreover, our Custom-house regulations do not at present permit of the temporary importation of automotors.

Yours faithfully,
The Director-General.

Rome, *May 10th*, 1898.

Denmark.

Sir,—In answer to your letter of April 26th, I received a letter to-day from the Chief Inspector of Customs, saying that motor-carriages and motor-cycles could be brought into this country free of duty if the Custom authorities are of opinion that the vehicles are brought into the country for the owner's own use, and that they have already been used before. If owner brings his vehicle with him no documents are necessary, but if vehicles are sent and arrived before or after owner's arrival a declaration as to above facts must be produced. The delay in answering is caused by Custom authorities.

I am, Sir, yours faithfully,
SOMERS BOYLE, Capt., *H.M. Consul.*

British Consulate, Copenhagen,
May 12th, 1898.

AUSTRIA.

Sir,—In reply to your letter of the 18th inst., I beg to inform you that private owners of motor-carriages and motor-cycles coming to Austria only for purposes of pleasure, with the intention to leave the country again with their vehicles within a fixed time, have to notify this to the Custom-house on their crossing the frontier, when they will be required to deposit the duty of £7 10*s.* fixed for each carriage, and extra the amount for the machinery as per weight, for which they will receive an official certificate of deposit.

On their leaving the country within the prescribed time, the duty thus deposited will be returned to them against delivery of the official certificate of deposit, and after proper identification of the vehicle, which on entering the country will be provided with an official stamp.

I am, Sir, your obedient servant,
M. FELDSDIARCK, *H.B.M.'s Consul.*

British Consulate General, Vienna,
May 24th, 1898.

BELGIUM.

Sir,—The question contained in your letter of the 18th inst. has been placed before the Customs authorities here, and their reply is as follows:—

"Carriages imported into this country for touring purposes are admitted free *provisionally*, but the amount of the duty must be deposited with the Customs officials at the port of entry against a transit receipt, giving an exact description of the carriage; the deposit can be recovered on production of this receipt, when the travellers leave the country, which need not be by the same route as they entered it. The duration of the tour must not exceed six months."

The Customs duty is fixed at 12 per cent. *ad valorem.*

I am, Sir, yours faithfully,
W. LYDCOTTE, *Acting Consul General.*

British Consulate General, Antwerp,
May 25th, 1898.

REFERRING to the letter from the Director-General of Customs at Paris to the Secretary of the Automobile Club of Great Britain (*see* THE AUTOMOTOR, p. 289, No. 20, May 16th, 1898), stating that Customs dues paid on the introduction of motor-vehicles into France will, if those vehicles are used only for personal purposes during a limited period, be refunded, the Secretary of the Automobile Club has been making enquiries as to what the dues precisely are.

He has sent us the following letter for publication:—

[Translation.] Douanes. Direction de Boulogne,
Boulogne, *June 12th*, 1898.

To Monsieur JOHNSON,
Secretary of the Automobile Club of Great Britain,
4, Whitehall Court, London, S.W.

Sir,—You did me the honour to write to me on the 10th inst. to ask me what are the Customs dues applicable to motor-tricycles and motor-carriages on their entry into France.

Velocipedes, of all sorts, driven by a motor have to pay the tax of ordinary velocipedes on their total weight, including motor.

As to motor-carriages, they belong to the class of the "coaches, properly so called," but their motor is admitted separately under the head of "thermal engines," except in the case where it is impracticable to separate the motor from the carriage; then the whole is taxed as "coaches, properly so called."

You will find hereunder extracts from the table of dues which concern these various articles:—

I. *Velocipedes.*

			francs.	
Minimum tariff			220	per 100 kilog.
General tariff	products of European origin		250	,, ,,
General tariff	products of extra-European origin	imported direct	250	,, ,,
General tariff	products of extra-European origin	imported from European ports	253·60	,, ,,

II. *Coaches, properly so-called.*

			Carriages weighing 125 kilog. or more.	Carriages weighing less than 125 kilog.	
			francs.	francs.	
Minimum tariff			50	120	per 100 kilog.
General tariff	European products		60	150	,, ,,
General tariff	Extra-European products	imported direct	60	150	,, ,,
General tariff	Extra-European products	imported *vià* other ports	63·60	153·60	,, ,,

III. *Thermal Machines.*

			Motors weighing 250 kilog. and over.	Motors weighing less than 250 kilog.	
			francs.	francs.	
Minimum tariff			12	20	per 100 kilog.
General tariff	European products		18	30	,, ,,
General tariff	Extra-European products	imported direct	18	30	,, ,,
General tariff	Extra-European products	imported *vià* other ports	21·60	33·60	,, ,,

The vehicles in question being, as my Administration informed you on April 26th last, admissible by the privilege of deposit, it is on these bases that the total dues to be deposited until the time of re-exportation should be calculated.

I am, Sir, &c.,
THE DIRECTOR.

[A kilogramme = 2·2055 lbs. (avoirdupois); 2 cwt. = (roughly) 101½ kilogrammes.—ED.]

THE Secretary of the Automobile Club of Great Britain also gives us the following information, which may be of service to those who intend to spend their autumn vacation on a motor-vehicle in France or Belgium:—

Particulars concerning the Transport of Motor-Carriages between Newhaven and Dieppe.

Price of Ticket for Single Journey.—A motor-car with four wheels, £4 0*s.* 3*d.* A motor-car with three wheels, £3.

Boat Service.—Motor-carriages would probably be taken by the cargo boat, which starts from Newhaven in the morning between 10 and 2, and from Dieppe in the afternoon. A day's notice should be given to the Superintendent at these ports. It is possible that the Superintendent might arrange to take the carriages by the night passengers' service.

London, Chatham, and Dover Railway.

The rate for taking a motor-car from Dover to Calais is £2 12*s.*, and from Dover to Ostend £3 4*s.* 4*d.*

Self-Charging Motor-Vehicle.—Mr. L. Epstein has recently patented a new electric motor-vehicle, in which he claims to have overcome the difficulties presented by batteries becoming exhausted at a distance from a charging station. It is admitted that it is one of the great drawbacks of electric motor-cars that the batteries require periodical recharging, this necessitating the existence of charging stations, and considerable rough usage of the accumulators in taking them out for charging and putting back in position again. These drawbacks are said to be avoided by the Epstein motor-car, which is self-charging, inasmuch as it is equipped with the necessary apparatus for automatically charging the cells whenever and wherever required, with very little difficulty. The car is equipped with Epstein cells of a special type, and an oil engine, and the motor can be reversed for use as a dynamo for the purpose of charging the cells. The extra equipment is stated to be responsible for an additional weight of only 3 per cent., compared with the ordinary electric motor-car. The weight of a self-charging car, complete, with all equipment and four passengers, comes out at something under 30 cwt. The accumulators weigh 7 cwt., and are considered sufficient for a 60-mile run on ordinary roads. We understand, says the *Electrical Review*, that Mr. Epstein now has one of the cars in course of construction.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to THE EDITOR OF "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. KING AND CO., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents:—*

London: POTTLE AND SONS, 14 and 15, Royal Exchange, E.C.
Wholesale: BRETT AND CO., 5, Pilgrim Street, Ludgate Hill, E.C.

Birmingham: J. MCCANN, 37, Union Street.

Manchester: JOHN HEYWOOD, Deansgate.

Newcastle-on-Tyne: C. C. ROSS, 35, Side.

Paris: HOMÈRE MOREAU, 97, Rue Nollet.

Victoria (Australia): PHILLIPS, ORMONDE, AND CO., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

Most of the back numbers can still be obtained at 6d. per copy, or 7d. per copy post free.

INDEX TO VOL. I

Is Published Free with the October Number.

NOTICE.—A few copies of Volume I, bound complete, can still be supplied at One Guinea net, in consequence of our having purchased some of the numbers out of print, enabling us to make up some more complete sets.

COVERS FOR BINDING VOLUME I

Price 1s. 6d.; *Post Free*, 1s. 9d.

Can be obtained through the usual Agents, or direct from the Publishers.

Proprietors and Publishers—F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

JUNE 15TH, 1898.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month.

1898.	
June	International Italian Exhibition of Motor-Vehicles (Turin).
June 10 to 25..	Motor-Vehicle Exhibition, Paris. Automobile Club of France. Sections—(*a*) Automotor vehicles which have given proof of their practical efficiency; (*b*) Industries connected with automobilism; (*c*) Motors adapted for automotors; (*d*) Vehicles adapted for automotors.
June 15 to July 15	International Concours of Automobile Tricycles and Bicycles in connection with the Turin (Italy) Exhibition.
June 25 and 26	Brussels to Spa Race. Organised by the Automobile Club of Belgium.
July 3 to 11 ..	Race from Paris to Amsterdam, under the auspices of the Automobile Club of France.
July 17 to Aug. 1	Lille (France) Motor-Vehicle Exhibition.
July 30 and 31	Automobile Race, Lille to Boulogne.
August 22 to Sept. 3	Engineering, Machinery, and Motor-Car Exhibition. Royal Agricultural Hall, Islington.
Nov. 18 to 26..	Stanley Show of Cycles, Motor-Carriages, &c. Royal Agricultural Hall, Islington.
1899	Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.
1900	Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

JAS. REEVES (Hampstead).—It is said that the delay in putting more electric cabs on the streets arises from the fact that the Electrical Cab Company are full up with orders from private individuals.

PETROL.—You cannot make a joint with red lead or insertion, the oil will dissolve it. Cut a piece of cardboard the size of the flange and steep it in hot glue; then make your joint. When it leaks tell us.

J. CHALMERS (Coventry).—Perhaps the valves are wrongly set. Turn the fly-wheel over slowly and watch how they act.

X. Y. Z.—Mr. Crowden's address is Motor Works, Leamington.

J. H. (Ayrshire).—Your best plan is to apply to the solicitor who has been conducting the proceedings on behalf of the shareholders. He will no doubt give you full particulars of how the matter stands.

INVENTOR.—Two letters are waiting you here in respect to your advertisement, and will be returned by us if they are not claimed within a few days.

B. H. (Bournbrook).—By applying to the solicitor in the proceedings you may possibly be still in time, seeing that you have not consented to the scheme of reconstruction.

W. DAVY (Royton-on-Tyne).—These small high-speed motors, such as the Bollée and the De Dion, are fitted with two valves only, the admission and exhaust. You will see a good account of these motors in the "Manuel Pratique du Conducteurs d'Automobiles," par Pierre Guédou.

PETROL.—The present price of petrol at Paris is 32 francs per 100 kilolitres, or, retail. 23½ francs per hectolitre. Essence, sp. gr. 700-710, costs 37 francs per 100 kilolitres.

CHAIN (Liverpool).—You will see some excellent examples of the effect of wear and tear on the Renold chain in the London electric cabs. We have often stopped and examined this chain gear. The study is interesting and instructive.

H. W. (Liverpool).—Your letter is much too long for publication inasmuch as the criticism you make is not either in accordance with facts or with engineering science.

THE LIVERPOOL TRIALS.

THERE was a particular fitness in the general order of things in the selection of Liverpool as the place in which the first trials of motor-vehicles intended for heavy traffic should take place. As the cradle of railway locomotion it is only proper that heavy road locomotion on a practical scale should be inaugurated there also. Of the success of the new or rather revived system of transporting goods there can be no question. Not only have these trials demonstrated that loads of 5 tons, or including the vehicle 9 tons, can be moved at an average speed of four miles per hour over some of the steepest and most badly maintained county roads we know of, but that this can be done at a cost far less than can be done by horses drawing the same load. Indeed, it would not be possible to attempt with horses the work done by these vehicles, known officially as Nos. 3 and 5. To haul these loads by horses would require such a number as to make the cost prohibitive, and, secondly, no cart-horse can maintain a mean speed of four miles per hour for 8 or 10 hours continuously, even allowing time for baiting. Liverpool people exhibit a rather childish pride in their no doubt very excellent horses, but what do these animals effect? They laboriously haul loads of 3 or 6 tons at a pace which any respectable tortoise would certainly not call fast, while as for loading up a lorry with 5 tons of bacon or cotton and sending that to a destination 35 miles away, it is by horse haulage a commercial impossibility; such a journey would occupy 17 hours, and require, at least, this number of horses. To have publicly demonstrated that this can be accomplished by steam motor-vehicles with ease and certainty and in about 9 to 10 hours, is an object lesson of the greatest possible value. These trials have, in fact, revealed possibilities about road locomotion which even the most sanguine hardly anticipated. They mark the inauguration of the era of cheap internal transport, and the first to avail themselves of the many advantages of motor-vehicles for the collection and distribution of heavy goods will be, if our information is correct, the railway companies.

Concerning the trials themselves we fully describe these elsewhere. It may possibly be a matter of regret to some that only four vehicles took part in the competition, especially considering the elaborate preparations made. On the other hand, these four vehicles were essentially practical machines, and each and all demonstrated their ability to carry their loads. Throughout the trials there was nothing in the nature of a total breakdown. At no time was there any trouble with either the boilers or machinery. There was at all times ample power at hand, and this was at all times transmitted without any hitch. Even when, owing to the absence of drain-cocks on the cylinders, the low-pressure cylinder cover of No. 1 blew out, this caused no delay whatever. So far, then, we have this salient fact to remember—that as regards the bodies, framing, suspension, transmission gearing, motors, boilers, furnaces, &c., there are several designs which can be regarded as thoroughly practical and reliable. These trials abundantly prove this. The weak point about all the vehicles was the wheels. In the early days of the locomotive the village blacksmith fitted ordinary farm wagon wheels with disastrous results. Some of our designers have fitted the very heaviest lorry wheels as drivers on their motor-vehicles with equally disastrous results. The question of the proper design of wheels is not a difficult one, but we are rather surprised to see that makers cling to the wooden cart wheel, which is merely a roller and not designed for, nor capable of, transmitting power under such severe conditions as obtained during the trials. Messrs. Thornycroft have, however, taken up this wheel problem, and we may be sure that in their hands it will be satisfactorily solved. Had, then, it not been for faulty wheel design, these trials would have been one unqualified success. Of course all sensible people will recognise that this wheel trouble can be remedied. We take some credit for the success of these trials in that the principles of design that we have persistently advocated in THE AUTOMOTOR have been to a very large extent followed by the various competitors, although these features of design were utterly at variance with those advocated by so-called "authorities." Thus we have advocated framing of the highest grade channel steel, fast running motors, water-tube boilers carrying high steam, hard bronze pinions, steel wheels, wide tyres, &c. These features are found prevailing to a greater or less extent in all the vehicles. Yet the "authorities" recommended timber framing, slow-running engines, wooden wheels, and all the other characteristics of an absolutely impossible vehicle. It is this clinging to obsolete precedent that hampers progress in every direction. Had Mr. Thornycroft clung to the traditions of the elders he would never have produced his 30 knot torpedo-boats, and had he followed the advice of the "authorities" on automotor vehicles he would never have produced No. 3. We were also assured that the vehicles would experience a lack of adhesive power. We clearly laid down the conditions under which this would occur some time ago.* These conditions did not obtain at the trials, and so there was no lack of the necessary adhesion. As regards stopping and starting on steep gradients, these vehicles were all that could be desired. They were at all times under perfect control. Their brake power was excellent. In fact, in every respect, save that of the wheels, the trials must be considered a great success.

Although up to a certain point these trials are of very great value as telling us much of the capacities of the various vehicles, yet they were by no means so exhaustive nor so conclusive as they might have been. For instance, neither the brake horse-power nor the draw-bar pull of the vehicles was measured. As regards the former, this is perhaps not so important from the purely commercial point of view, but in any motor it is always desirable to have this information and a trial cannot be considered as possessing much scientific value if steps are not taken to obtain it. As regards the latter, it would have been of practical value to have ascertained what load and at what speed these light locomotives could haul other vehicles as allowed under the Act. It would also have been of great utility to have carried out brake tests in a more scientific manner. The stopping tests were all very well in their way, but it would be useful to know in what distance No. 3 can be stopped on a down grade of 1 in 25. It will thus be seen that the trials do not possess much scientific value as the dynamical issues have not been considered.

It only remains for us to cordially congratulate the Liverpool branch of the S.P.T.A. and their executive, especially the hon. Organising Secretary, Mr. E. Shrapnell Smith, on the completeness of their arrangements and on the general success that deservedly attended their efforts. But how can we find words to express our appreciation of the Lancashire County Council for their provision of such atrocious roads, the worst of which were, with a discrimination that deserves every praise, carefully selected by the executive of the S.P.T.A. as the scene of the trials? Liverpool is a magnificently paved city and an example to many others, but if a heavy steam motor-vehicle can negotiate the disgracefully kept roads of the Lancashire County Council it can with every confidence be relied upon to go anywhere. No trials could have been more severe. We attended Les Poids Lourds trials at Versailles last year and thought the *pavé* was bad enough; but the routes around Versailles are, compared with the Lancashire roads, as asphalte to macadam. Roads such as one sees in Lancashire would not be tolerated in the environs of London, Paris, or Berlin.

In dismissing the subject of these trials, there are some matters which might call for candid criticism, but for the present we leave them.

* *Vide* THE AUTOMOTOR, March, 1898.

THE BRITISH MOTOR SYNDICATE AND GREAT HORSELESS CARRIAGE COMPANY.

WE publish a letter from a correspondent, which is only a sample of several others that we have received, in consequence of the statement in our last issue that the *dissentient* shareholders in the British Motor Syndicate had been settled with. Another gentleman writes from Ayrshire as follows:—"I have been advised to consult you and ask for information regarding a committee of shareholders in the British Motor Syndicate, which has been formed to look after their interests in that unfortunate concern. I had allotted to me 50 shares, on which I paid 10*s.* per share; but, finding that certain statements in the prospectus were misleading, especially the one referring to the price in the market, I bought 50 shares in the market, for which I paid £73, and refused to take up the 50 allotted or to pay the calls on them. I have been lately threatened with an action in Court for recovery, and, being informed that a committee has been formed of those in like circumstances, I would take it as a great favour if you would give me particulars at your earliest convenience concerning it." And, again, another reader from Torquay writes:—"I am an unfortunate holder of a considerable number of Great Horseless Carriage Company shares, being an original allottee. Observing an article on this subject in your journal for May of this year, I should esteem it a favour if you could put me in the way of obtaining some return for the money I have paid—110 shares, £1,100. I did not concur in the recent reconstruction scheme, and have declined to accept the reconstruction terms, as it appeared to me to be throwing good money after bad. At the same time, I have always considered that the way in which the original Company's shareholders were treated was quite unreasonable, and that this good money had been recklessly squandered." Having given the names of the acting solicitors in this matter as requested, we understand from one of our correspondents that the reply he received was to the effect that he was too late in seeking to co-operate with the other shareholders, and would require, therefore, to make the best terms he could for himself. The terms upon which the actions were stopped are that each of the plaintiff shareholders received 20*s.* in debentures for every pound paid by them. Thus fully-paid holders received £3 in debentures for each £1 share held by them, and in addition the Syndicate and Mr. Lawson conjointly and severally covenanted by deed to purchase such debentures at the price of 15*s.* in the pound at any time within a certain period at the option of the holders. Partly-paid holders were relieved of all liability for calls and received debentures to the full amount of the money paid by them, with a guarantee to purchase at rates varying according to the calls they had paid. In addition to this Mr. Lawson has paid the costs of the solicitor who acted for the shareholders. On the whole, considering the great uncertainty of litigation, we cannot help but think the shareholders have been well advised in accepting this settlement, and no doubt if our several correspondents communicate direct with Mr. Lawson, under existing conditions, we should imagine there would be very little difficulty in their exchanging their old shares for new debentures in like manner with the rest of the shareholders.

PETROLEUM AS A FUEL FOR AUTOMOTOR VEHICLES.

By BOVERTON REDWOOD, F.R.S.E.

IT is well known that liquid fuel has for many years been very extensively employed in steam raising, and those who have travelled in the oil-burning steamers on the Caspian Sea, or behind the oil-fired locomotives on the southern Russian railways, have had an opportunity of observing the advantages attaching to the employment of this source of heat. Amongst these advantages are the following:—

(a) Comparatively high thermal efficiency, the evaporative power being, under favourable conditions, practically double that of good steam coal.

(b) Economy of space in stowage, liquid fuel being far less bulky than coal, weight for weight.

(c) Saving of time and labour in handling, oil-tanks being filled far more quickly than coal bunkers, and the manual work inseparable from the employment of solid fuel being almost entirely dispensed with.

(d) Facility of control in firing, the regulation of the heat being effected with remarkable ease in accordance with varying requirements.

It is obvious that these features of superiority must be specially valuable in the use of liquid fuel in vehicles propelled by steam on the highways, and it is not surprising that this combustible agent has been thus applied with remarkable success. By the provision of a suitable regulator the supply of oil to the burner is so controlled that the working pressure of steam is automatically maintained, and blowing off at the safety valve is prevented. It must be admitted that in the construction of the burners difficulty has been experienced in the attainment of satisfactory combustion without the production of noise, and that in this respect there is room for improvement; but this is not a serious defect, especially when the vehicle is employed for commercial purposes, and will not weigh heavily against the important advantage that in using liquid fuel, with an automatic feed, it is not necessary to have a stoker in addition to the driver.

It appears unquestionable that the steam-engine may be utilised as a source of power in road vehicles carrying heavy weights, with the same measure of success as now attends the employment of the Daimler motor for lighter work; and as some description of mineral oil seems to be the ideal fuel, it is necessary that those who are interested in this development of automobilism should preserve an attitude of watchfulness in reference to projected legislation, lest the use of the cheapest and most suitable oils for the purpose should be interfered with.

THE LIVERPOOL TRIALS AND THE LOCAL PRESS.

SPEAKING generally, the Press has exhibited a commendable spirit of impartiality in discussing these, and we note with pleasure that the feelings of rabid hostility, born of intolerance and nursed on ignorance, which have characterised the utterances of not a few London and provincial journals, have now given place to more enlightened views. Journalists, like other preachers, have had to recognise that there are more things or more latent possibilities in various masses of matter than have been contemplated in their philosophy. The motor-vehicle is one, and illumination by electric oscillations is perhaps another. Judging from the general tone of the Press on these and kindred matters, it would seem that very few journalists possess the scientific mind, or realise or appreciate the significance of the conclusion reached by a very great authority to the effect that we are now on the eve of some discoveries in physics that will give mankind the control of hitherto unknown, although suspected, natural forces. It is quite likely that just as an uninstructed public opinion retarded the introduction of railways, and just as an uninformed Press hindered the progress of automobilism, so it is likely that a similar lack of appreciative discrimination on the part of the Press may positively act as a brake upon the wheels of progress, and it may happen in the future that the great power of the Press may be much lessened owing to its inability to lead public opinion in the paths of progress. These conclusions are forced on us as the result of studying the wavering and wobbly attitude of the Press since the passing of the Locomotives on Highways Act. But a little acquaintance with history, a little knowledge of the mechanical history of our own times, would, if honestly reflected on, have saved many a newspaper from stultifying itself. We could mention influential newspapers which a year ago made automobilism the occasion for much silly and hostile diatribe, but which now recognise that it is a practical factor in our social life.

On the other hand there are a few newspapers that from the first have recognised the importance and significance of the new movement. Among these the *Liverpool Daily Post* deserves honourable mention. It has done a great deal in impressing common-sense views upon that very common but very singular person the "man in the street"—without whose co-operation even a Ministry cannot exist. Speaking of these heavy motor trials our contemporary says in its issue of the 28th ult.:—

"Liverpool has had abundant evidence this week that motor-cars have passed the purely experimental stage. . . . . Whether the trial of the lorries will convince business men of their value for the conveyance of heavy goods by road instead of by rail or canal has yet to be seen, but that a self-propelled lorry can do what no horse-drawn vehicle of similar type can accomplish is conclusively demonstrated. . . . . So far as these various matters are concerned, the trials, we believe, have established the fact that self-propelled lorries are much more under control than horse-drawn vehicles, and the success with which they mounted the long and steep hill from the bottom of William Brown Street to the top of Prescot Street places their climbing powers beyond question. On the country roads, on a fairly level or gently undulating surface, about six miles an hour was attained by two very business-like vehicles, one carrying about 2 tons and the other a load of 4 tons. A third lorry carrying 2 tons travelled at a much greater speed, and kept up a velocity of about nine miles an hour. The speed, however, was accompanied by a deafening noise that greatly alarmed horses, whereas the vehicles going at about six miles an hour caused less noise than an ordinary horse-drawn lorry would if it were possible to drive it at that speed. . . . . The trial of these heavy goods self-propelled vehicles, therefore, is a matter of very great importance for Liverpool, and the opinion of practical business men upon them will be awaited with deep interest. It is quite possible that they may entirely revolutionise heavy road traffic, and compete successfully with railways over comparatively short distances."

Tyre or Tire.—Writing to the *Morning Post* of the 31st ult. "Philologus" says:—"Now that all the world is mounted on wheels is it not time that the orthography of this indispensable part of a bicycle were settled? One cannot take up a newspaper without seeing the virtues of so-and-so's 'tyres' extolled. Yet I cannot find any English dictionary which recognises any other spelling except 'tire.' Skeat says: 'Tire, a hoop of iron that binds the fellies of wheels,' and quotes from Phillips, ed. 1706, 'Tire, the ornament of women's heads, the iron band of a cart wheel,' adding, 'Probably identical with tire, a woman's head-dress.' It is surely appropriate that the wheel which so many ladies adorn should have the same 'tire' as the heads of the owners display." We may point out that, notwithstanding the authority of Skeat, custom, the sole arbiter on these questions, has always spelt the hand of a wheel as "tyre." Shakespeare, no mean authority—we quote from the "Universal" edition—always uses "tire" in the sense as pertaining to a woman's head-dress, while the Local Government Board Regulations on the Locomotives on Highways Act also spells the hand of a wheel as "tyre." We submit that this latter spelling is the more correct as it means a definite thing, whereas "tire" means, according to Shakespeare, a head-dress, to fasten, to fix talons on, to be idly employed upon; while "tired" means to be adorned with ribbons. We might thus say a locomotive or motor-vehicle was "tired," meaning either that it was adorned with ribbons or had hands of some material on its wheels. "Tyre" is good English. "Tire" savours of philological agnosticism, and reminds us of those barbarisms much affected by the *Daily Chronicle*, such as "program," "labor," "honor," &c. We prefer "tyre."

THE SECRETARY OF THE SELF-PROPELLED TRAFFIC ASSOCIATION.

AT a recent meeting of the Council of the Society of Accountants and Auditors, Mr. Andrew W. Barr, of 30, Moorgate Street, was unanimously elected President. Mr. Barr is known to our readers owing to his being professionally associated with the Self-Propelled Traffic Association, and his portrait will be found in our special Supplement issued with the present number.

Mr. Barr, who has only been in practice on his own account since 1886, has, before reaching the age of 33, attained the highest honour his profession can confer on him. Everyone who knows Mr. Barr will, we feel sure, agree with us in congratulating him on his elevation to a post of considerable professional importance.

The London Carriers and Automobilism.—Our big carriers are evidently one by one seriously taking up the question of utilising motor-vans for their business, the latest, we notice, being the well-known firm of Messrs. T. M. Fairclough and Sons, who are connected with the Motor-Van Syndicate (Limited), recently formed for the purpose of exploiting motor-vans, both Messrs. M. and A. Fairclough being associated as directors.

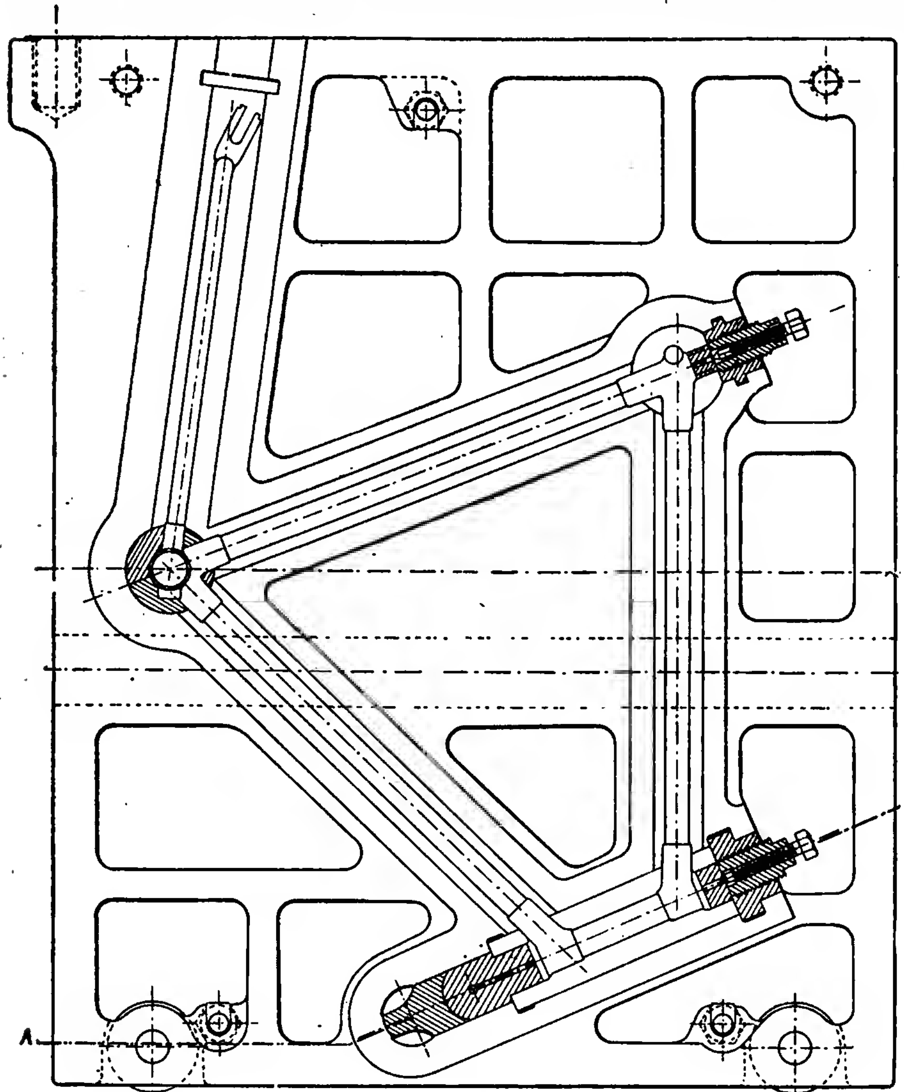
THE Société des Automobilce "Elan" has been formed in Parie with a capital of £800, and the Société Anonyme du Palais de l'Automobile et du Cycle with a capital of £12,000.

HYDRAULIC JOINTING.

OF all the parts that go to make up a steam-engine, or indeed any motor that works by the pressure of gas or fluid, none are less mechanically satisfactory than the joints of the pipes that convey the motive power. Especially is this so in the case of steam pipes; the general practice is to braze on the flanges to each length of piping, but this produces a joint which may or may not be reliable, and if the machine is subjected to much vibration, the chance of a rupture, with possibly disastrous results, is by no means remote. Indeed, many disastrous explosions of steam pipes have occurred during the last few years from the fracture of the pipe at the brazing. Even for lighter work, such as attaching the sockets to cycle frames, brazing is unsatisfactory, as the great heat takes the elasticity out of the metal and causes it to twist. With a view to obtain a perfect mechenical joint, it occurred to Mr. Chas. T Crowden, of Leamington, to form the socket with a series of internal corrugations, and to expand the tube into these. This he ultimetely effected by assembling the parts together and placing the whole within a mould or matrix, and then subjecting the tube to internal hydraulic pressure. The effect of this was to force the metal of the ends of the tube into these internal corrugations, and thereby a very stroug and mechanically perfect joint was obtained. By placing the tube and sockets in a mould as stated, the only place at which the metal could flow was et the ende within the sockets. A joint so formed is homogeneous throughout, and is much stronger than the rest of the tube. The security of the junction is increased by the fact

FIG. 1.—HYDRAULIC JOINTING (General View).

that during the process the outer tube is itself slightly expanded, but well within the limits of elasticity; so that after the internal pressure is removed, and the process is completed, the outer tube, from its elasticity, closely grips the inner tube. Hydraulic pressure up to



INSIDE VIEW

SECTION THROUGH A.B.

FIG. 2.—HYDRAULIC JOINTING.

5 tons to the square inch can be readily applied, but in practice it has been found that with iron or steel tubes of light section very much less than that is sufficient to expand them. Where softer material than steel is used it can be worked with simpler apparatus, and in these cases expensive machinery is not required.

In the latter part of 1896 Mr. Crowden demonstrated the practicability of his process before sever

stroke, it is worked by steam at 120 lbs. pressure per square inch; the total pressure on the piston being about 24 tons. The mould is shown in Fig. 2, with a cycle frame in position. As before said, this mould is made in two halves, one being mounted on a travelling carriage. A frame having been assembled together in one half, the other half is placed against it and clipped to it; steam is then admitted to the cylinder and the piston urged forwards, closely pressing, by means of the toggle levers, the two parts of the mould together; while so held by the piston rod means are provided for securing the levers in this position and the piston is allowed to go back, in order to make its second stroke. A prolongation of the piston rod, 2 inches diameter, forms the plunger or ram of a hydraulic pump, which now comes into action. Water is automatically admitted to the cycle frame, and the orifices in the press closed. Steam is now again admitted to the cylinder, and by means of suitable nozzles a connection is made from the pump barrel to the cycle frame, the water within the latter is put under pressure, and a final pressure of 3½ tons per square inch given. The piston is now allowed to go back, the toggle joint released, and the press opened, by sliding one part back, the cycle frame is taken out completed, ready for the enameller, and another put in its place, the whole operation taking about three minutes.

The completed joint is shown in Fig. 3; as will be seen, the corrugations are given a helical shape, this is to prevent any twisting. The press, as shown in Fig. 2, can only be used for that particular shape of frame, but as these presses are of cast iron there is no difficulty in moulding them to take any desired shape; in this way tubes of any size can be flanged or socketted. There is an extremely wide field for the operation of this process, cycles being but one of the many purposes to which it is applied. We may expect to see it extensively used for the framing of light motor-vehicles.

A DAIMLER MOTOR-VEHICLE FOR HEAVY LOADS.

Our illustration represents a goods wagon for 5 tons load as built by the Daimler Motoren Gesellschaft, of Cannstatt, Germany. The wagon is equipped with a 10 H.P. motor, and has a four-speed gear, besides a reversing motion. The carriage is said to be able to negotiate gradients of 10 per cent. when fully loaded and can go at 12 kilometres (seven miles) per hour on the level road.

From our engraving it will be seen that steering is in front, the motor and regulating mechanisms being arranged above the front axle. A suitably journalled shaft conveys the motion to the rear portion of the wagon acting upon the rear (driving) wheels. The tyres of the latter are notched on the periphery to assist adhesion. The front wheels (steering wheels) are of 960 millimetres (38 inches) diameter, being 100 millimetres (4 inches) wide in the rim, whilst the drivers are of 1,150 millimetres (46 inches) diameter, and 120 millimetres (4¾ inches) wide. Petrol and cooling water are stored below the platform. The seat of the driver is immediately behind the engine, the steering being effected by means of the handwheel visible in the accompanying engraving.

Wagons of this description carrying building materials in the southern districts of the Schwarzwald on a road eight kilometres (five miles) long, having gradients of 7 and 8 per cent., consume per hour 4·5 litres (one gallon) of petrol, which costs just now 70 to 80 pf. (8·4*d.* to 9·6*d.*). With this quantity the empty wagon can run 11 to 12 kilometre hours (6·8 to 7·5 mile hours), whilst it will suffice for eight kilometre hours (five mile hours) when fully loaded, allowances made for the state of the road and gradients encountered.

THE FRENCH LAW OF MOTOR-VEHICLES.

By M. G. Plé.

(From *La Revue de Méchanique.*)

Horses are often frightened when they see an automoter carriage for the first time. The form of these vehicles, the noise they make, the smoke they pour out cause these animals such fright that they rear, swerve on one side, and often cause accidents more or less serious. Are the conductors of automobiles always responsible for accidents? and when are they? A judgment given by the Court of the Seine appears to lay down the exact principles necessary to determine these questions.

The conductor of a horse-drawn carriage was following a course by keeping to the right, when he perceives two automotors coming towards him on the same side of the course as he was himself. In order to leave a free passage the conductor took the left side of the road. At the instant that the automotors arrived near the carriage, the frightened horse swerved aside and upset his master into a ditch, who, in his fall, broke his leg. In consequence of this accident the injured man made a claim for damages against the proprietors of the automotors. He based his demand at the time on the error they had made in keeping to the right of the road, and that conductors of automotors should be made to take greater precautions than ordinarily in consequence of the dangers which this class of vehicle gives rise to.

The Court held at first that the fact of the conductors of the automotors keeping to the right had nothing to do with the accident; that this fact and the injury failed to establish a ground of action, and in effect failed to establish a lien which was necessary in order to establish the responsibility of the defendants. Moreover, they had proved that they had not committed an imprudence; that the automotors were not going at an excessive pace; that they were not making an abnormal noise; that the horse had not shown signs of fright before the accident, and that its movement was made abruptly in the passage of the automotors, that is to say, too late to stop the vehicles; that under these conditions the defendants had not infringed any rules that discretion had imposed in such matters. Consequently the demand was rejected, and the judge did not consider the responsibility rested with the proprietors of the automotors (Civil Court of the Seine, February 16th, 1898).

In order to fix the responsibility of an accident on a person it is necessary for the fault to be committed by him. This principle is applicable to proprietors of automotors as to everyone else. If they cause an accident through going too quickly or not stopping or slackening speed when a horse shows signs of fright, they commit an error of which they must take the consequences. But if the accident is caused through the sudden and unexpected fright of a nervous horse at sight of an object new to him, they cannot be declared responsible. However, as prudence and imprudence are things on which opinion is liable to vary, personal interest, not to mention humane reasons, command proprietors of automotors to exercise extreme care, as they run a risk of incurring grave consequences in the event of it being shown that they in any way omitted to do anything which prudence and common sense would suggest.

Motor-Vehicles and the Police. — The polices authorities at New Scotland Yard have granted a new kind of traffic license. They have been waited upon by a deputation of motor manufacturers, and several types of petroleum motors and omnibuses have been submitted for examination. Some singular tests were applied, says the *Daily Chronicle*, the chief inspector riding by the motor man, and directing operations. These included driving in and out between moving traffic, turning in small circles, and suddenly pulling up short at given signals. Results clearly proved that the motor traffic is quite as safe in London streets for all practical purposes as the present horse-drawn traffic. The outcome has been that Mr. Lawson duly received on Saturday morning (the 4th) an intimation that the Commissioners have decided to license for ordinary carriage work in London the type of motor-vehicles submitted for examination, which included petroleum and Daimler cabs and carriages. It is said that a new type of London omnibus, driven by motor engines, will now follow. It is intended that these buses shall run to and from Brighton daily, calling at all the small towns and villages *en route.* To bring the green fields round London and even sea shores within easy reach by turnpike road will prove an unlooked-for public benefit to the credit of our motor-car inventors.

NOTES OF THE MONTH.

The new Electricab for London will be painted blue with white lines.

The Mechanical Traction Syndicate and the Westralian Motor Company have been wound up.

The lightest tubing ever made is of nickel aluminium, and measures 0·036 inch outside diameter with walls 0·0015 inch thick; 3,000 feet of this tubing weigh only 1 lb. avoirdupois.

A second motor-vehicle has been delivered at Dundee from the makers for the Dundee and District Tramway Company. After a satisfactory trial it was put into service. A third vehicle is expected next week.

We regret to record that Mr. Charles Herbert, manager of the Mannesmann Tube Works, Swansea, committed suicide, on the 6th inst., by leaping from the railway bridge near Llandore Station, falling on the flags in the river below. Excessive overwork is assigned as the cause of the act.

Street car axles are being made at Krupp's works, Essen, with 7 to 8 per cent. of nickel, as are also hollow driving axles for locomotives. In fire-box steel as much as 25 per cent. of nickel is said to be used. Less than 7 per cent. of nickel does not seem to be thought of any value in locomotive axles.

"Furniture moved in our own motor-vans" is the announcement that one enterprising firm make in the Midlands, and another equally enterprising firm of grocers "dispatch all parcels the same day as ordered by motor-van, thus saving the delay and expense of railways and Post Office parcels post."

A new line of omnibuses has been started in London, running from Child's Hill, Hendon, to Oxford Street, while the London General Omnibus Company have, in response to a deputation from local tradesmen, extended the route of some of their Kilburn buses to the Finchley Road, in order to provide better communication between the various parts of Hampstead. Arrangements are also being made to start an electric omnibus line from the Swiss Cottage, running up Fitzjohn's Avenue to a point close to the summit of Hampstead Heath.

The coachmakers and wheelwrights of London are, it is said, trying to arrange for an amalgamation of their forces. There are about 15,000 employed in those branches of trade, only about 1,500 of whom are in union. According to the reports, the rates of wages are so low that they are little better than those paid to unskilled labour, and yet considerable skill is required of men working at those trades. The objects of the federation are to abolish piece-work, establish a minimum wage, and generally to improve the condition of the workers.

Several of the American railway companies are experimenting with nickel steel as a material for locomotive parts, such as piston-rods, stay-bolts, crank-pins, and driving axles. The increased cost is said to be ¾d. per lb. for 3 per cent. nickel steel, as compared with ordinary mild steel; so that the cost of a locomotive having these parts of the new material would not be greatly enhanced, whilst it is hoped to greatly reduce breakages by the change. The use of nickel steel for the framing and wheels of motor-vehicles has been persistently urged in The Automotor.

Handsome gold and silver medals have been awarded by the Edinburgh Cycle Trade Association to Stirling's Motor-Carriages (Limited), and the Beeston Cycle Company (Limited), respectively, in connection with the motor-carriages and motor-tricycles exhibited at the February show of the Association. The medals are large and very handsome.

At the recent meeting of the Horses Committee of the St. Helen's Town Council, Councillor Forster suggested that the committee should consider the advisability of purchasing a couple of steam or electric motors for scavenging work. The motors would probably be found much more economical than horses. Councillor Brown, deputy chairman, said he would be glad to bring the question before the committee.

One of the strongest agricultural associations in Lancashire has been formed for that most important portion of the county comprised between the Lancashire seaboard at Lytham and Bleasdale Hills in the east, sweeping round the outskirts of Preston and including a portion of Clitheroe Union. The society is headed by the principal influential territorial owners of the county, and Lord Derby has signified his acceptance of the presidency, to which he was unanimously invited.

More newspaper science! The *Globe*, in the course of an article on "The Motor's Delay," gives the following explanation of the difficulties of automobilism on roads:—"But the jarring which is set up on a rough macadamised road knocks the machinery to pieces, and if this is strengthened all round it becomes too heavy both in weight and price, *while if a particular bar is made heavy to resist strain, it will break by its own weight.* The condition of our roads is, therefore, the real cause why the automobile has as yet only so narrow a margin of advantage over the horsed vehicle as to make its introduction slow." The italics are ours.

Motor-cars were somowhat in evidence at this year's Derby, and in proof of the rapidity with which the prejudice of the public against these vehicles is being lived down, whore 18 months ago they would have beeu greeted with howls and shouts of derision, it is worth noting that during the whole route there was hardly a voice raised other than to cheer. The Coventry Cross Cycle Company, of 80, Oxford Street, and Coventry, who are generally to the front when any special form of advertisement can be procured, chartered three Daimler vehicles, which ran to Epsom and back without the smallest hitch from first to last.

The Scotch Court, says a writer to the *Times*, with reference to patent case trials, does not allow more than two expert witnesses on each side, it does not permit the introduction of irrelevant matter, and it discourages a practice which has taken root in the English Courts of allowing advocates possessing some scientific attainments to assume the functions of experts instead of confining themselves to law. In cases of doubt or difficulty the judge summons to his assistance a man of science or of practical knowledge in whom he has confidence, and obtains from him definite answers to specific questions framed by the judge himself. We commend the Scotch practice.

Road railways—for such the new tramway lines worked by electricity are—will have a great impetus given to them this year in the number of schemes soon to be put before the Light Railways Commissioners, and in others now formulating. It is proposed to apply for the sanction of a line of this kind to run between London and Oxford, and another, which would really be only two miles longer, although the scheme sounds much more important, is proposed along the old coach road between London and Brighton. Through services would not, of course, be run on these lines, but between such centres, for instance, as Brixton and Croydon, Croydon and Redhill, and so forth.

Electric motor-vehicles are gradually being introduced on the South Side Elevated Railway—Alley Line—at Chicago, to replace the steam locomotives which have hitherto been used. Experiments have been in progress for a long while, and some of the cars are now in service, the trains consisting of four or five cars. The Sprague system is used, in which each car has its own electrical equipment, but all controlled from the front car. This is the last line to make the change to electric traction, and when its engines are taken off there will be no steam locomotives on any of the Chicago elevated railways, but steam locomotives will be used for many years yet on the London underground lines.

THE PARIS-AMSTERDAM RACE.

This race, or race and tour, to Amsterdam has been organised by the Automobile Club de France, and will start from Paris on July 5th. There will be three classes of four-wheeled vehicles, the first class being those carrying two persons, the second those carrying four to five, and the third class those carrying six or more. The motor-cycles will include two classes: those weighing from 100–200 kilogrammes, and those less than 100 kilogrammes. These two classes will again be subdivided into those carrying one or two persons. The following are the programmes for those taking part in the tour and for those racing:—

Touring.

July 5th.—Paris-Reims, *vid* Meaux, La Ferté-sous-Jouarre, Montmirail, Champaubert, Epernay.
„ 6th.—Reims, Rocroy, Fumay, Givet, Dinant, Namur.
„ 7th.—Namur, Liège, Maestricht.
„ 8th.—Maestricht-Nymègue.
„ 9th.—Nymègue-Amsterdam.
„ 10th, 11th.—Stay at Amsterdam and excursion to La Haye.
„ 12th.—Amsterdam-Nymègue.
„ 13th.—Nymègue-Liège.
„ 14th.—Liège, Pepinster, Spa, Trois-Ponts, Houffalize, Arlon, Luxembourg.
„ 15th.—Luxembourg, Longwy, Verdun, Châlons-sur-Marne.
„ 16th.—Châlons-sur-Marne, Paris.

Racing.

July 7th.—Paris-Dinant.
„ 8th.—Dinant-Nymègue.
„ 9th.—Nymègue-Amsterdam.
„ 10th, 11th.—Stay at Amsterdam and excursion to La Haye.
„ 12th.—Amsterdam-Liège.
„ 13th.—Liège, Luxembourg, Verdun.
„ 14th.—Verdun, Châlons, Paris.

An elaborate set of rules has been drawn up, indeed, the Automobile Club apparently like a good number of rules, and in this respect it resembles our Jockey Club and our Yacht Racing Association, and all arrangements made to provide petrol *en route*, effect repairs, accommodation, &c. The trip should prove very interesting and enjoyable.

HORSE AND MOTOR-VEHICLE ACCIDENTS.

Turning Corners.—On the afternoon of June 3rd, as the pony trap of Mr. E. Pearson, J.P., was being driven from Morton House to Gainsbro', a motor-vehicle belonging to Mr. Heinle, a local tradesman, came suddenly around a corner, causing Mr. Pearson's pony to swerve to the opposite side of the road. The pony was thrown down, the trap was damaged, and the driver received a severe shock.

The Dangers of Nervous Horses.—While Colonel Spilling was driving, on the 25th ult., from Casterton to Tukencote in a trap, his horse shied at a passing motor-vehicle and, taking fright, dashed off at a great speed, upsetting the trap and throwing out the occupants. Colonel Spilling was badly hurt and the trap much damaged.

REVIEWS OF BOOKS.

Owing to the great pressure on our space in this issue, we are compelled to hold over our notices of the following works till our July issue:—

"Electro Dynamics: The Direct Current Motor," by Chas. Ashley Corus Wilson, M.A., &c. (Longmans, Green, and Co., Paternoster Row, London). Price 7*s*. 6*d*.

"Lubricants, Oils, and Greases" (Spon and Chamberlain, London and New York). Price 4*s*. 6*d*.

"Acetylene Gas and Calcium Carbide," by G. F. Thompson, Consulting Engineer, Liverpool. (Published by the Author at Liverpool Chambers, Sixteth Street, 1898.)

"Garnet du Chauffeur," par le Comte de la Valette (Paris: Riberre et Fils, Éditeurs, 15, Rue Grevier-Saint-Lazare, 1898).

The Engineering Magazine, Cassier's Magazine, La Revue Mechanique, &c.

CATALOGUES.

A brightly written and copiously illustrated catalogue of the "Monarch" marine and stationary gas and gasoline engine has been sent us by the makers, the Grand Rapids Gas Engine and Yacht Company, of Grand Rapids, Michigan, U.S.A., whose agent on this side is Mr. A. Evans, of 107, Wool Exchange, Coleman Street, London. For all purposes to which light oil-motors are applied the "Monarch" seems, from the numerous testimonials given, to answer admirably, while the prices are such as should lead to an extensive business. For launch and small yacht propulsion the motor appears to be well designed and of very moderate weight. It, of course, works on the Beau de Rochas cycle, but its valve motion seems to possess some improved features.

We have also received:—*The Journal of the Society of Arts, The Indian Engineer, Industries and Iron, The Practical Engineer, Coach-Builders' and Wheelwrights' Art Journal, The Journal of Acetylene Gas Lighting, Knowledge, Machinery Market Review, The London Chamber of Commerce Journal, Indiarubber World, Cyclist, Scottish Wheel, Irish Field, The Yachting World, The Engineering Magazine, La Revue de Méchanique, La Locomotion Automobile, La France Automobile, L'Industrie Velocipédique et Automobile, L'Automobile Illustré, La Moniteur Automobile, La Revue des Transports Parisiens, Les Sports, L'Energie Électrique, Der Motorwagen, Samokat, Horseless Age, American Wheelman, The Motocycle, Australasian Coach-Builder and Saddler*, &c., &c.

THE BRUSSELS-SPA MEETING.

This meeting has been organised by the Belgian Automobile Club and it will commence on June 25th. On this and the next day the motor-vehicles will run from Brussels to Spa in two stages. There will be seven prizes for voitures and the same number for motor-cycles, ranging from 2,500 francs and a gilt medal for the winner in the former and from 500 francs for the winner in the latter. There are also numerous other competitions in which large money prizes, medals, &c., are offered, including prizes to the most suitable vehicles for touring, country service, &c. The race from Brussels to Spa is confined to amateur as distinguished from professional drivers. Owing to the legal regulations as to speed it would not appear that much in the nature of racing, as understood in France, can be accomplished.

On the 27th and following days there will be held at the Brussels Exhibition various receptions, banquets, &c. On the 29th the prizes will be presented, including two from Sir David Salomons, President of the S.P.T.A., one of 300 and one of 200 francs for the most elegant vehicle. On July 3rd there will be a race for motor-cycles, in connection with which prizes of 1,000 francs will be awarded.

THE CAIL MOTOR.

M. EDOUARD CAIL, of the Société Anonyme d'Automobilism, has endeavoured to deal with the important problem of vibration in motor-vehicles, and with a view of lessening this vibration and also to improve the carburisation of the air forming part of the charge to the cylinders he has designed a motor which we illustrate in the accompanying drawings. Fig. 1 is a sectional elevation and Fig. 2 a horizontal cross section on line 1—2 of Fig. 1, of what is termed an equilibrated motor, according to this invention, while Fig. 3 is a central longitudinal section of the carburettor.

The motor comprises several juxtaposed cylinders, the one illustrated by way of example having two cylinders, A and A^1, independent of each other and mounted on the same casing, B, which serves as a bed plate. This casing carries the bearings receiving the journals of the crank-shafts, C and C^1, provided with balance weights, D and D^1, and driven by rods, E and E^1, respectively connected to the pistons, F and F^1. On the cranks, C and C^1, on the opposite side to the balance weights, are mounted cylindrical toothed wheels, G and

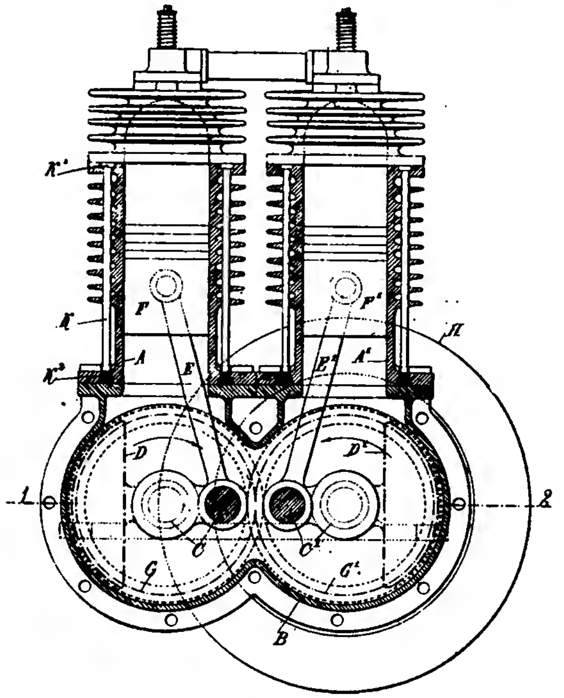

FIG. 1.—VERTICAL SECTION.

G^1, of equal size. All these parts—cranks, balance weights, and gears—are enclosed in the casing, B, where they work in oil. Only one of the crank-shafts, say C^1, carries the fly wheel, H, and at the other end, at I^1, the ignition mechanism for the cylinder, A^1. The other crank-shaft, C, only carries, at I, the ignition mechanism for its cylinder, A. Each cylinder has a separate valve gear similar, like the ignition devices, to those of ordinary motors. The cylinder walls, A and A^1, are very thin and strengthened by ties, K, the heads, K^1, of which are let in into the upper flanges of the cylinders, the other ends being screw-threaded for receiving nuts, K^2, sunk in the opposite flanges, these nuts being suitably tightened to stretch the ties, K. A sufficient number of such ties considerably strengthen the cylinders and enables the latter to be made much thinner, thus considerably reducing the weight of the motor.

The cranks, C and C^1, are opposite each other and rotate in the opposite directions owing to the engagement of the toothed wheels, G and G^1. Each piston, F and F^1, completes a four-stroke cycle, and the two cycles are so performed relatively to each other as to effect one explosion for each revolution of the fly wheel. The pistons have the same advance movement, that is to say, they move together and when the explosion acts, say on F^1, the piston, F, is drawing in its charge and *vice versâ*, which is easily obtained by suitably arranging the valve gear. In this way, it is claimed, the shocks produced by the explosion or compression of gases on one of the pistons are compensated for by the shocks on the other piston, which act in the opposite direction—a rather questionable assumption. The momenta of the two balance weights, D and D^1, are added to the force of the explosion, the result being, we are told, a complete suppression of vibrations.

The carburettor for this motor comprises a chamber, *a*, to which oil is supplied through a nozzle, *b*, ending in a capillary orifice, *b*^{1}, which may be closed by the point of a rod, *c*. This rod can move in a passage made for the purpose in the wall of the chamber, *a*, and is under the influence of a spring, *c*^{1}, which always tends to hold it against one of the ends of a lever, *d*, whose other end carries a float, *e*, which may be lowered from the outside by pressing on a spring knob arranged for the purpose on the cover of the chamber, *a*. The

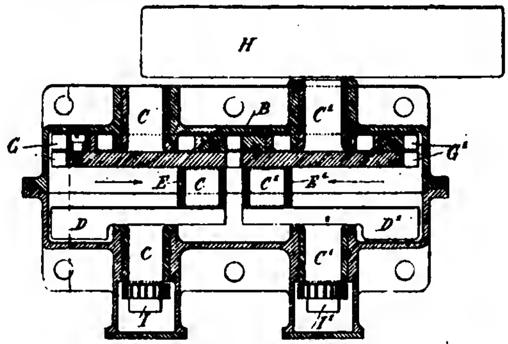

FIG. 2.—HORIZONTAL SECTION ON LINE 1—2.

oil passes through the conduits, *n n*^{1}, to a capillary orifice, *n*^{2}, at a small distance above which there is a disc, O, arranged like the orifice, *n*^{2}, in the centre of the chamber, *l*, communicating on one side with a hot-air supply pipe, Q, and on the other side with a suction pipe, R, leading to the cylinders, A and A^1 (Figs. 1 and 2), and with a pipe, S, opening into the atmosphere. A cock or plug, T, which can be operated from the outside by means of a small lever, *t*, can partly or entirely close the opening through which the pipe, R, communicates with the chamber, *l*.

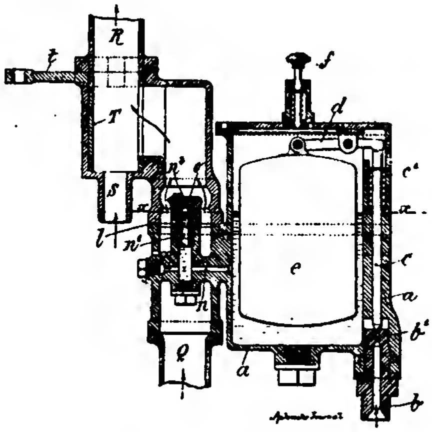

FIG. 3.—SECTION OF CARBURETTOR.

The oil is always maintained at a suitable level, X—X. When the engine is to be started, the fly wheel, H, is rotated as usual and the knob, *f*, is pressed so as to sufficiently lower the float, *e*. The result is that the level of the carburetted liquid in the chamber, *a*, and conduit, *n*^{1}, rises and the oil escapes in the shape of a very thin sheet under the disc, o. During the suction period the air entering by the pipe, Q, takes up the liquid thus divided, becomes suitably carburetted, and the mixture passes to the cylinders through the pipe, R, together with the cold air drawn in through the branch, S. When the explosion takes place the knob, *f*, is released and the suction produced by the piston draws in the oil through the opening, *n*^{2}, under the disc, o, where it mixes with the hot air arriving through the branch, Q, and the same operations are repeated as described. When the level of the oil sinks the float, *e*, descends and turns the lever, *d*. The rod, *c*, rises under the influence of the spring, c^1, its point opens the passage, b^1, through which the liquid enters the chamber, *a*, which is arranged lower than the supply tank which communicates with the branch, *b*. When the level rises the float, *e*, also rises, the lever, *d*, lowers the point of the rod, *c*, into the passage, b^1, and shuts off the supply of oil to the chamber, *a*.

THE PARIS MOTOR-CAB COMPETITION.

It is not too much to say that in Paris, as in London, the public are heartily sick of the typical cabman. For generations this individual has been tolerated as a necessary nuisance, and he has taken full advantage of the position. In both cities, and, for that matter, in nearly every city, he exhibits the same characteristics. Horsy and coarse in his general behaviour, he is abjectly civil to those who, careless of money, pay him not less than twice or thrice his proper fare, but a bully of the first order to women and defenceless persons, from whom he will endeavour to extort as much as possible. He is one of the few tradesmen who deem themselves affronted by the tender of a legal fare. In his driving, especially in Paris, he is often criminally reckless, and in London it is only by a very necessary and wholesome police supervision that he is restrained at all. The cab, too, is like its driver—an uncomfortable but necessary nuisance; both are now, thanks to the advance of automobilism, in the course of being improved off the face of the earth, but the process has only just begun. In Paris, so rapid has been the growth of automobilism, and so popular are motor-vehicles, by reason of their greater safety and comfort, that the ordinary voiture is likely to be, within the next few years, wholly eliminated from the streets. Apart from the reasons we have mentioned as accounting for the popularity of the motor-vehicle, there are two others. Only fairly wealthy companies can afford to run them on commercial lines; this means that the charges and earnings are fixed on commercial principles. It also means that the driver or conductor becomes the servant of the company owning the vehicles, and hence can be made amenable to the civilising influences of discipline and good behaviour. We have a notable instance of this in our London omnibuses, the conductors, as a rule, being very civil and well behaved men. Again, some skill is required, or rather skill demanding a higher order of intelligence is required of the driver of a motor-vehicle; this means that instead of a hulking, horsy person, smelling, speaking, and thinking of the stable, a distinctly superior person, and more reliable, has to be employed. For these reasons it is not surprising that Parisians favour motor-vehicles so much.

In order to select types most suitable for the Paris traffic, the French Automobile Club instituted a competition which, at the time of writing, is in progress. A strong Committee was appointed to arrange the details, consisting of MM. Bixio, Monmerqué, Jeantaud, Baron Rogniat, Hospitalier, Comte de la Valette, Comte de Chasseloup-Laubat, Thévin et Houry, Solignac et Eschwège.

It was decided that the competition should embrace a period of 12 days, commencing on June 1st and terminating on the 12th. The vehicles were required to traverse Paris and its environs in various directions, and to ascend the steepest gradients, the steepest, we understand, being 1 in 15. Each vehicle was required to cover a distance of about 36 miles each day. The Judging Committee was required to pay particular regard to the working cost of a journey of about 36 miles as a minimum in a day of 16 hours; also comfort, ease of manipulation, frequency of replenishing the source of motive power, and the facility for repairs were points to which they had to pay special attention. The vehicles were classed as under:—

1st Class.—(*a*) Closed vehicles for two persons.
(*b*) Open vehicles for two persons, but fitted with a hood.
(*c*) Vehicles for two persons, that can be readily made open or closed.
2nd Class.—(*a*) Closed vehicles for four persons, with roof for carrying 66 lbs. of baggage.
(*b*) Open vehicles for four persons, fitted with hood.
3rd Class.—Closed vehicles for six persons, with roof for carrying 66 lbs. of baggage.

The rules for the construction of the vehicles were very stringent, and, needless to say, the police requirements had to be scrupulously observed. In Paris the speed was not to exceed 12 miles per hour. Official observers were appointed to accompany each vehicle and take notes of the proceedings. Arrangements were made for recharging the batteries of those vehicles using electricity as the motive power; these charging stations were under the control of special commissioners appointed by the Automobile Club. At the Clichy Central Station the charge for current was 0·30 franc per kilowatt. In order to determine the amount of current, &c., taken by each vehicle a special jury was formed, consisting of six members of the Automobile Club and of six persons appointed by the competitors. Each competitor was required to furnish particulars as to the voltage necessary for recharging; whether the current required was constant or intermittent; time required for recharging, &c.; whether the vehicle could perform each day's run without recharging, &c. Each vehicle was required to be furnished with a tested ammeter and voltmeter.

The depôt was situated at the corner of the Rue de Courcelles and the Quai Michelet. The first day's run on June 1st was devoted to obtaining data as to resistance to traction and consumption trials. It was arranged so that the batteries should be weighed either on the day or on the last day, at the option of the competitors. On the last day—the 12th—there was a procession of vehicles to Versailles, returning *viâ* Longchamps. Prizes of 2,000 francs were given by the General Cab Company of Paris and of 1,000 francs by the Association of Cabowners.

It goes without saying that the competition was entirely between petrol or spirit motors and storage batteries supplying current to electrical motors. In all 25 vehicles were entered as will be seen from the following table:—

—	Makers.	Type.	Method of Propulsion.
1	Krieger	Coupé ..	Electricity.
2	"	Victoria ..	"
3	"	Tractor ..	"
4	Panhard-Levassor	Coupé ..	Petrol.
5	"	Victoria ..	"
6	"	Landau ..	"
7	"	Fiacre, roofed.	"
8	"	Omnibus ..	"
9	Prétot	Tractor ..	"
10	Cie. franç. de Voitures Electromobiles	Coupé ..	Electricity.
11	" " "	Victoria ..	"
12	Société des Automobiles Peugeot	Coupé ..	Petrol.
13	Cie. Gle. des Transports Automobiles	—	—
14	Brùlé & Cie.	Cab	Petrol.
15	Cie. Gle. des Automobiles ..	—	—
16	Krieger	Coupé ..	Electricity.
17	Cie. Gle. des Voitures a Paris ..	" ..	"
18	" " " ..	Victoria ..	"
19	Agence générale des Automobiles	Coupé ..	Petrol.
20	Doré	" ..	Electricity.
21	Jeanteaud	" ..	"

23	"	Coupé ..	"
24	"	Landaulet ..	"
25	"	Drojski ..	"
26	"	Cab avec, seat behind	"

Of the 15 vehicles but 12 put in an appearance. Eleven of these were electrically driven, all of which were fitted with the Fulmen accumulator, of which a long and interesting description appeared in the last number of THE AUTOMOTOR.

Very great surprise was experienced that only one petrol motor-vehicle appeared to take part in the trials, this was a Peugeot cab. The competition hence resolved itself into a test of various types of electric cabs. The reason for the withdrawal of the makers of petrol motors is stated to be that the Paris cab companies, after exhaustively testing various types of vehicles propelled by the latter means, have concluded that for, at any rate, cab service in the city petrol motors are unsuitable, by reason of the heat, smell, and vibration to which they are liable, especially in the hands of unskilful drivers. This decision will come as a serious blow to those who look forward to the employment of petrol cabs in London. On the other hand, the great improvements that are constantly being made in storage cells, the extension of electric-light stations, and the continual diminution in the price of current, coupled with the freedom from vibration, the absence of noise, heat, and smell, all point to the electric cab as the most suitable motor-vehicle for town service. For country and private use the petrol motor has, however, the field to itself. This conclusion is of far-reaching importance, and deserves the most serious attention of all interested in automobilism.

The data obtained of the power consumed in the electric cabs is very valuable, as throwing considerable light upon the rather debated question as to the power necessary to propel vehicles. Thus the Krieger No. 1 weighed, in running order, with three persons and 150 lbs. of luggage, 2,992 lbs. On the flat, on wood pavement, the current was 20 ampères at an E.M.F. of 80 volts; on asphalte the current was 15 ampères; and on macadam 26 ampères. On a steep gradient with macadam the speed was 3·6 miles per hour and the current 56 ampères at 85 volts E.M.F. The total consumption of energy for the route of 36 miles, and a very hilly one with indifferent roads, was 8 kilowatts. In our next issue we hope to describe these trials more fully.

The trials at the time of writing are in full progress, and all the vehicles are, so our Paris Correspondent advises, behaving remarkably well, notwithstanding the very severe conditions of the tests. The report will take quite a month to prepare, so, as with our own competition, judgment must be suspended for the present.

THE WORK DONE IN HAMMERING.

MR. CH. FREMONT has recently contributed to the "Proceedings" of the French Society of Civil Engineers the results of some very interesting observations on the work done by hammer-men in riveting or at the forge. By means of kinematographs he was able to trace the full line of travel of the hammer in different cases, and to calculate the work done with considerable accuracy. The rivet hammers used weighed from 3·3 lbs. to 3·7 lbs. each, or 4·4 lbs. with handle included. Completing the head was done with hammers weighing 9·9 lbs. to 11 lbs. each, these being used either swung or raised. The photographs showed that on the rise the hammer moves slowly, but rapidly increases in speed on its descent. Using heavy hammers without swinging them, a good striker makes 12 blows in 15 seconds, and does in this time 2,386 foot-pounds of work or 159 foot-pounds per second. This rate cannot, however, be maintained, and if the periods of rest are few and short, as in horse-shoe making, the rate of work falls to 108 or 115 foot-pounds per second.

On the other hand, an exceptionally good man can for a short period work at the rate of 202 foot-pounds per second. When in place of the hammer having a movement of a quadrant only, it is swung the full circle, fewer blows are struck per minute, but the work done by each blow is greater. Thus, with a 15·4-lb. hammer about nine blows would be struck in 15 seconds, each of which would accomplish 231 foot-pounds of work; but the rate of working falls to 137·4 foot-pounds per second. Striking a side instead of a down blow, an ordinary man not specially accustomed to such work strikes 12 blows in 15 seconds with a heavy sledge, each of which is equivalent to from 145 to 149 foot-pounds, and the rate of work is 123 foot-pounds per second. With riveters accustomed to strike in this fashion, about 10 per cent. better results are obtained. Usually, however, they use a lighter sledge, weighing about 10 lbs., and with this can strike 13 to 14 blows in 15 seconds, doing 108 foot-pounds per second. Swinging the sledge, the number of blows falls to 10 in 15 seconds, but the rate of work is unaltered, owing to the blows being heavier.

When striking on a snap, the rate of work is 20 per cent. less. The hand-hammers used by riveters weigh 4 to 4½ lbs. each, and the work done per blow is 58 to 65 foot-pounds per second, four blows being struck in five seconds. Smiths using a 5½-lb. hammer strike one blow per second, and do work at the rate of 72 foot-pounds per second. In a shoeing forge the results are about 20 per cent. better. In general, it was found that with hammers weighing from 2 to 15 lbs. the work done was very uniformly equivalent to that due to a fall from a height of 13½ feet.

AN automobile club has been founded at Amiens on the initiative of M. Berson.

DOINGS OF PUBLIC COMPANIES.

"The Referee" Automatic Cycle Pump Company.

THE statutory meeting of this Company was held, on the 20th ultimo, at the offices, 4, Ludgate Circus, E.C. The directors, Mr. J. Adams, Mr. J. Cuthbertson, Mr. E. H. Neville, and Mr. J. B. Boyle, were in attendance.

The CHAIRMAN reported that the Company possessed a working capital of £6,500, and in addition owned the patents which had all been completed in France, Germany, Belgium, and Canada, and on these no liability in any way existed. The Company had not as yet parted with any of its foreign patents, though offers had been received for France, Austria, Australia, Canada, &c. The terms which the directors insisted on were in all cases a cash payment of not less than £1,000, and 25 per cent. of the shares in any Company to be formed, and they had obtained these terms in most cases. The contract for making the pumps had been placed with an English firm. Over 1,000 orders for pumps were now on the books for delivery, and 5,000 pumps were at the works being fitted, so that now there would be a continuity of supply and no delay in supplying customers. Inquiry had been made by a new firm who had introduced a pneumatic carriage wheel for a supply of pumps to them, and the development of the business would undoubtedly extend to all classes of vehicles, including motor-cars. Evidence of the utility and demand for the pumps was shown by inquiries which had been received from St. Petersburg, Canada, India, China, and, in fact, all over the world. Industry on the part of the directors had not been wanting, and the shareholders could rely on the best results attending their efforts.

Metropolitan District Railway Company.

THE QUESTION OF ELECTRIC TRACTION.

A SPECIAL general meeting of the proprietors of the Company was held, on May 17th, at the Westminster Palace Hotel, S.W., Mr. James Staats Forbes presiding, for the purpose of submitting certain Bills now pending in Parliament.

The CHAIRMAN said the first Bill referred to in the notice convening the meeting was entitled "A Bill for conferring further powers upon the Metropolitan Railway Company in relation to their own undertaking, and for the ventilation of their railway, and upon that Company and the Metropolitan District Railway Company in relation to the working of their undertakings by electrical power, and upon those companies and the South Eastern Railway Company with respect to certain lands at Cannon Street; and for other purposes." This Bill contained clauses which affected the District Railway, and it could not pass through Parliament until the proprietors had sanctioned it in respect of those particular clauses. In the early part of last year they passed two or three Bills, which were subsequently submitted to Parliament and approved. One of these gave them power, whenever the time was convenient and the method sufficiently developed, to apply certain funds of the Company for the purpose of working by electricity the railways of the Inner Circle. The Metropolitan Railway Company was applying for similar power, and, of course, the District Company could not dissociate itself from that Company in respect to electrical communication—they were bound to work in harmony. The clauses in the Bill affecting the District Company were Nos. 24 and 38. The former empowered the Metropolitan and District Companies to enter into agreements as to working of traffic by and supply of electrical power, and the latter empowered the South Eastern Railway Company to grant and the Metropolitan and District Companies to hold a lease of the portion of the forecourt of the Cannon Street Station of the South Eastern Company which was occupied by so much of the station and works of the Metropolitan and District Companies as was above or upon the surface of the forecourt. As the result of much negotiation and the award of an eminent judge the claims of the South Eastern Company had been settled, and would take the form of a lease of the land upon which the station stood, in respect of certain financial payments by the two underground companies. Of course the adoption of electricity was a matter they could not go into with absolute indifference as to the question of cost. A good deal, however, was now known about this form of traction. It had its advantages and its disadvantages; but the proprietors decided as far back as February last year that it was a matter they ought to be prepared to face at the right moment. Their idea was that £500,000 would be extremely well spent in adapting their railway to electrical traction over that particular part of it which he had mentioned, which was crowded with traffic, and so much of which was incapable of anything but very imperfect ventilation. They were instructed by very eminent authorities that the financial burden cast on the two companies would be extremely moderate in comparison with the great advantages to be secured not only by getting rid of many of the offensive qualities of the air in the tunnels, but also in the saving in the cost of traction, which they were advised would be considerable. The matter was one demanding some care, and they naturally wished to be in the hands of perfectly responsible engineers of eminence. In Sir J. Wolfe Barry, a man of considerable experience, who had advised the Company almost from its inception, and Mr. Preece, the electrician of the Post Office, and one of the most distinguished members of his profession, they had thought well to vest the preliminary inquiries. Those gentlemen were now concerned in the matter, and the directors would not proceed until they were assured by the report and recommendations of those gentlemen that it was safe to do so. They were gradually gaining experience in the matter of electrical traction. The greatest enterprise of the kind yet approaching to anything like development was the Central London Railway. They knew a little about the question from what had been done on the City and South London line and the Liverpool Overhead Railway, but the Central London Railway, which would be running by the end of this year or the beginning of next year, would doubtless open their eyes to a good many things. The experience of that Company would be very useful to the District and Metropolitan Companies. The Chairman then moved the approval of the Bill in so far as it affected the Company.

Lord Gort seconded the motion, and it was agreed to.

The Chairman explained that there was another Bill down for consideration relating to the Whitechapel and Bow Railway, empowering the District Railway and the London, Tilbury, and Southend Railway to subscribe to it; but the Bill was *in nubibus*, and therefore the consideration of the clauses affecting the District Company would have to be postponed. They would accordingly adjourn the consideration of that Bill until Thursday, June 9th.

Motor Manufacturing Company (Limited).

The first ordinary general meeting of this Company was held on the 17th ultimo, at Winchester House, Old Broad Street, E.C., Mr. John H. Gretton, presiding.

The Secretary (Mr. Alfred Burgess) having read the notice convening the meeting,

The Chairman said:—I think I shall be able to show you to-day that we have laid the foundation of a business which will, I think, be of an extensive character, and one which, I hope and believe, will be very profitable. I daresay you will agree with me that it will not be necessary to go back over the history of what took place in the past, except, perhaps, to contrast the conditions which prevailed previously with those which exist now. You are aware that under the old condition of affairs your Company only had the right to use patents which had been granted some time ago, and it was not entitled to use improvements upon those patents. Excluded from the rights which your Company enjoyed were the vehicles which, if I may use the expression, are practically at the present moment in fashion, namely, the Daimler motors on the one hand, and vehicles such as motor tricycles and bicycles on the other hand. Under the new condition of affairs your Company has the right to use all the patents of the British Motor Company in existence or which may be taken out in the future, together with all improvements connected therewith, and included in the rights which you possess are the rights to make Daimler motors, and also to manufacture the tricycles and bicycles over which the British Motor Company has rights, and if it purchases or becomes possessed of any other patents your Company will have the right to use all those patents. Then you have for working capital the considerable sum of £50,000, and your representatives on the shareholders' committee have the right to nominate all the directors with the exception of two, and it is due to that fact that I have the honour to appear before you to-day. I trust that the selection of my colleagues and myself which has been made by your representatives will meet with your approbation. Of course, you will want to know what steps have been taken to utilise the advantages which have been secured. I ought to have told you that, in addition to the advantages which I have enumerated, we have had handed over to us, free of any outlay on our part, the premises which were occupied by the former Company at Coventry, together with the plant and tools, and we have entered into negotiations for securing a large piece of land immediately adjoining, upon which it is our intention to erect a foundry, in order that we may manufacture the castings and fittings for the business which we intend to carry on on your behalf. I need hardly tell you that it is most important that the castings and fittings for these motor-vehicles should be most carefully constructed, and not only will this be of advantage to us in making it certain that the vehicles will be turned out without any risk of accidents happening subsequently, but we know that we shall have a business in supplying these castings and fittings to others. The next point which I think will interest you is that we have secured the services as manager of your works of an exceptionally good man. I refer to Mr. Iden, who for many years was in a prominent position in the locomotive department of the London, Brighton, and South Coast Railway at Brighton. He has there acquired an experience in the making of carriages, and he has particularly devoted his attention to the manufacture of motor-cars; he has, in fact, constructed a motor-car which we believe is certainly in advance of anything that has been previously constructed in this country, and equal to anything that has been constructed in France. I can assure you that your directors, without exception, are most desirous of doing everything they can in order to bring this business to a profitable result. Their time and energies will be devoted to endeavouring to produce satisfactory results in the shape of returns upon the money you have invested in this undertaking. In order to guide your directors in the course which it was advisable to pursue, and in order to carry out prudently the policy which I have indicated to you, one of your directors recently went to Paris with our manager. While there they went over all the principal works in Paris, they examined all the newest kinds of vehicle, and they have come back with knowledge of a very important nature. With regard to the industry in France, as you are probably aware, it is at the present moment in a very prosperous condition. The manufacturers there are not only full of orders, but it is very likely that if you wanted any of the popular vehicles at the present moment you could not procure one within at least four months, while in some cases you would have to wait as long as nine months. Now, we are, of course, devoting our attention principally to those vehicles which are in vogue at the present time. Our idea is not to manufacture a large variety of vehicles. We want to restrict our operations to certain types of vehicles which we believe will command public favour and will come within public requirements. We have had some experience, because we have been doing a fair amount of business already at the works. We cannot say, of course, that we are doing that amount of business that would be considered a highly remunerative industry just as it stands, but considering the short time that we have been in existence upon this new basis, I may say that our business is so far very satisfactory, and it teaches us a very important point, namely, the kind of vehicle to which it will be advisable for us to devote our attention. We have, among other things, been making small omnibuses for use in Scotland, and if that industry develops as it promises to do, it will, I need scarcely tell you, be a very important matter. We have in this hall a motor-bicycle, and I think that if you look at it you will come to the conclusion that it is a very handy little machine. One of the great advantages of it is that we should be able to sell it at a price which will come within the means of a great many people. My colleague, Mr. Robinson, who is intimately connected with the manufacture of these articles, will explain to you the different vehicles which are taking up our attention at the present moment, and which we intend to push ahead with. I might tell you in passing that out of 3,000 shareholders in the old Company 2,000 have come into this new Company. There is one thing that you can congratulate yourselves upon, and that is that you are in the movement of the future. I should imagine that no sensible man who sits down to think for a little while could doubt that this motor industry has an enormous future before it.

Mr. Thomas Robinson. I should like you to bear in mind the very grave difficulties which are associated with the starting of an engineering business. We have had the utmost difficulty, and are still experiencing it, in getting the necessary machinery delivered. It often takes from nine to twelve months to get delivered the machinery which is absolutely necessary for us to fit up our works properly. One of the first difficulties which this Company had to contend with was that our late works' manager at Coventry was unable to continue with the present Company. Everyone knows—

and especially those who have the management of engineering businesses—that there is no more difficult position to fill than that of works' manager. If he is not a clever man, the works' manager does more to wreck a company or a business than anything else. When your directors came in contact with Mr. Iden, the principal foreman of the locomotive works at Brighton, they came in contact with a man who was thoroughly fitted for the post. You may be interested to hear that at Brighton in one year he erected 32 locomotives and had over 400 through his hands for repair. In conjunction with Mr. Stroudley he erected a steam locomotive which was exhibited at the Paris Exhibition and gained the first prize. In addition, he had under his control the repair and keeping in order of all the machinery upon the boats running between Newhaven and Dieppe; and, as our chairman has said, Mr. Iden has experimented and made bicycles, tricycles, compressed driving apparatus, and, lastly, the motor-car. When in Paris recently I asked to be shown one of the latest motor-cars manufactured. I was considerably surprised to see that the motor-carriage brought out as one of the latest in Paris was a victoria of a type almost identical with that constructed by Mr. Iden. Following on the lines which the old Board had only initiated, we have mainly confined our attention to the manufacture of oil-motors. Ever since the present Board has been in office there has been a regular weekly turn-out of motor-cars of the pattern which you see illustrated on the walls to-day. If you will kindly look at the catalogues which have been distributed in the hall, you will see that types Nos. 1 and 2 are dog-carts, and these have been extremely popular. Only a fortnight ago we had a type No. 2 in our window at Holborn Viaduct. About three days after we had first shown it, a gentleman came in and purchased three of these, together with a wagonette, handing us a cheque for £1,000 as deposit with the order. If you turn to type No. 6, you will see the large wagonette to which the chairman has referred as being supplied by us with very great success to a company in Scotland. It is, of course, well known that the motors used in all these cars are Daimler motors, manufactured by the Daimler Motor Company. This has been a purely reciprocal business arrangement. We have manufactured different articles for the Daimler Company, and they in return have supplied us with motors; but we are under no obligation to order our motors from them; the arrangement under which we have worked being purely voluntary. This matter is one which has occupied the attention of your directors to a considerable extent, and as soon as they are satisfied that it will be in the interests of this Company for them to manufacture Daimler motors themselves, from that moment they will begin to manufacture them. Passing on to the next type of car which we manufacture, we come to No. 7, the Bollée voiturette. The French (Bollée) voiturettes which were put on sale by the former Company we do not consider of a satisfactory character. They were of French make, and were not at all to our satisfaction. To-day we have in hand and going through our works a number of these Bollée voiturettes of the latest type. It will no longer be necessary for the driver to get off the machine, and to go down upon his hands and knees, or perhaps to lie flat upon his back, to get at some portion of the machinery, as in the latest type that we are building all the parts have been fitted so that you can easily lift up the back seat and get at the machinery. Not only so, but the cars are being manufactured without the front seat, so that a gentleman can easily ride it himself, it being simply fitted for one. This voiturette in France has done 35 kilometres—21½ miles—in 36 minutes; but I would not advise any purchaser to attempt emulating that speed without first insuring his life. As our chairman has pointed out, this Company has the right to make cycles, and we propose to exercise that right, and to go in for the manufacture of motor-cycles. At the present time we are manufacturing a large number of De Dion motors, the same as is used in type No. 8 for the motor-tricycle; we have also an important order in hand for the motors alone. No one who has been in Paris and seen the hundreds of motor-tricycles running along the boulevards, or running down through the woods, can help being struck with the immense popularity of this form of oil motor for tricycles, and we believe that there is a big future for us in this direction. Then we have recently brought over and are arranging to manufacture a new moto-cyclette, a sample of which is exhibited this afternoon. It is the latest motor-cycle. The motor is just above the front wheel of the bicycle. It is very compact, the whole of it not weighing more than about 55 lbs. This motor is now being sold very rapidly in France, and we anticipate getting a number of them through our works within a month from to-day. The price will be somewhere about £45 or £50, which makes it the most moderate article of the kind yet placed upon the market. I had hoped to be able to show it in actual working in this hall to-day, but the room is hardly suitable. We should, however, be pleased to allow any shareholder to see it in actual operation upon the Company's premises, and I may here add that we shall be pleased to supply shareholders with this moto-cyclette at £5 less than the ordinary price. So much for oil; then there are also steam and electricity as motive powers. So far as steam is concerned, there is no doubt that for heavy traffic, such as a big omnibus trade, steam will play a very important part, and upon this point we have not been sleeping. I had the advantage of going down with Mr. Iden to see, I think, all the steam omnibuses now being made in France. The steam omnibuses of Count de Dion are now doing daily passenger service at Mentes. We motored down there one afternoon—a distance of nearly 40 miles from Paris—and upon inquiring of a proprietor of a horse drawn omnibus whether the steam bus was running there, he poured forth a dismal tale of misfortune into our ears. It appears that since the steam bus has been upon the road he has had to reduce his price from 1 franc to 50 cents. and 75 cents., and, notwithstanding this, he finds the greatest difficulty in securing passengers. We learned that if there were 20 persons in the station each would prefer paying a slightly higher fare in order to complete the journey of 7½ miles in from 28 to 30 minutes, instead of being in a horse-drawn bus for nearly an hour and a half. While we were at the Count de Dion's he showed us a cheque for 23,000 francs which had just been received as a deposit upon three motor-omnibuses, and judging from the saving which is made, and from the working and running upon the roads, we are of opinion that there is a very great future for the manufacture of these steam buses in this country. We feel that, from Mr. Iden's long experience on locomotive designing and building, he is pre-eminently fitted to advise the Company in the manufacture of steam buses, and your directors are determined to place this Company ahead of all others in this particular branch. So far as electricity is concerned, experiments will have to be made; and here the ground is less sure. Your board has decided—I think, wisely—to, as far as possible, avoid experimenting, and to let this Company's business proceed upon sound, known, definite lines. At the same time the British Motor Company has arranged to give this Company the option of building the cars for the Electric Cab Company, if we wish to have it, and we hope that in the future there will be a considerable business in that direction. In conclusion, I may say we calculate that at the present time the receipts about balance the expenditure. Since the present Board has been in office, in orders and receipts we have come somewhere near £10,000, and we have only to steadily proceed upon the same lines for this Company to be a sound commercial success. When all the various cars and bicycles now in course of manufacture are turned out, we anticipate that this Company will be placed in a totally different position even from what it is to-day. We have laid, and are still laying, broad foundations, and the result, we believe, will be a solid, sound, and yet rapid development. If any unprejudiced shareholder, or if any prejudiced shareholder, were to go to Paris and visit the various motor manufacturing works there, I have no doubt he would be convinced, from the astounding results and the great development of the business, as to the future of the industry. He would see businesses which a short time ago made no profit—in fact, which made a loss year by year—now for the first time in their history doing an enormous business and making great profits. If he went, for instance, to the works of M. Chauvu he would find that Bollée voiturettes are being taken out at the rate of 45 to 50 per month, and would find an order-book with 200 to 300 orders in arrear. If he went further on, to Puteaux, he would find that Messrs. De Dion and Bouton's factories, covering some two acres of ground, are turning out 400 to 500 motors weekly, and that they are some 1,650 motors and motor-cycles behindhand in delivery. If he went on the other side of the road, to the enormous factories of two or three acres which they are now building for erecting steam omnibuses, he would learn that it will be a difficult matter to secure the delivery of omnibuses under about 12 months. If he went to the other side of Paris, where Messrs. Panhard and Levassor are turning out motor-cars, he would find that their orders for motor-cars alone for the month of March amounted, roughly, to £51,000. If you go to Paris you will see that under the very patents under which we are working, and in the manufacture of the very cars that we can make, they are doing this prodigious business. We believe that by turning out cars which shall rank side by side with any that are produced on the Continent the prospects of this Company cannot fail to increase, and we believe that upon those lines it has a bright, solid, and I believe I may properly say a brilliant future before it.

Replying to questions, the CHAIRMAN said that the directors appointed by the shareholders' representatives were Mr. R. Hoffman, Mr. J. H. Mace, Mr. Buckea, and himself, and that Messrs. H. J. Lawson and Thomas Robinson were appointed by the British Motor Company. With regard to Mr. Lawson, he was authorised to say that that gentleman's resignation was at all times in the hands of the Board, and if at any time they thought it advisable, in the interests of the Company, to dispense with his services, they were free to do so. For the present, however, they certainly did not wish to take advantage of Mr. Lawson's resignation because they had a controlling power on the Board, and they believed his knowledge and experience would be of great value in the interests of the shareholders.

A vote of thanks to the chairman, proposed by Dr. DRYSDALE, closed the proceedings.

New Motive Power Syndicate (Limited).

THE report of the directors for the year ended December 31st, 1897, submitted to the general meeting held at the Holborn Viaduct Hotel on May 19th (when a motion to admit the Press was negatived by 20 votes to 14), states that the Board had hoped before this to have made satisfactory arrangements for the sale of the Syndicate's interests, but the negotiations which were pending were unfortunately interrupted by Mr. Guattari, the inventor, and engineer to the Syndicate, suddenly leaving London, professing to have been called to the Continent by illness in his family and not returning. Inquiries were immediately instituted, when it was discovered that Mr. Guattari had settled in Belgium. By request of the directors their chairman was deputed to go over and see him, and he there made arrangements for his return to England, but the directors regret having to report that, up to the present, those arrangements and promises made from time to time have not been kept. The inventor's failure in carrying out his undertaking to return has interfered with the directors' plans and caused considerable delay, but they have now entered into a conditional contract for the sale of all the patents held by the Syndicate, except the Belgium patent. The directors believe the proposed sale is beneficial to the shareholders, and submit it to them for their consideration and approval if so decided. The full details of this arrangement and the contract were submitted at the meeting. The secretary, in a circular accompanying the report, asked for proxies to be signed in favour of the directors. To this request a counter circular was sent out by Major-General Henry P. Babbage and Messrs. Thomas Holden, Charles G. Dean, Thomas Neary, John W. Kersley, and John Kiofe, asking shareholders to cancel any proxy already given and "await a full and satisfactory exposition of the terms proposed, which it is hoped will be attained by the appointment of a committee to fully consider them and to report thereon to an adjourned meeting of the shareholders."

New General Traction Company (Limited).

THE second annual general meeting of this Company was held on May 17th at Cannon Street Hotel, Captain Francis Pavy (chairman) presiding.

The SECRETARY (Mr. A. De Turckheim) having read the notice calling the meeting,

The CHAIRMAN, during his speech, said: The history of the Company can be told in a very few words. Some few years ago my friend on my right, Mr. E. A. Hopkins, conceived the idea that there was room for a Company doing electric traction business, and he with a few friends started a Company and began operations. He began at Coventry and at Douglas, in the Isle of Man, and after he had made some progress he found so many matters submitted to him that he put himself into communication with me with the object of my giving him some assistance in enlarging the Company's sphere of operation. We began in a small way and went on quietly, and succeeded in getting Acts of Parliament for Norwich and for the extension in Coventry, and we have been able, without any difficulty, to issue £100,000 of preference capital, which brings our total capital, including ordinary shares, up to an amount of £270,000. That progress in electric traction must be made in Great Britain I have very little doubt about. We are far behind most other countries in this matter. I find, for instance, that there are over 1,300 companies in the United States, with 16,000 miles of electric tramways and 45,000 motor-cars, and that the amount of capital invested in the United States in this particular kind of business is over £100,000,000 sterling. It is true they have a population of 70,000,000, and a very much larger area than we have. We have only 38,000,000 to 40,000,000, and our country is much smaller; but there is more activity and more movement in English towns than in the towns and cities of the United States, and I think that public attention should be directed to the immense facilities for travel that would be afforded to people if they had electric tramways. There is no city in the United States with a population of 6,000 or 10,000 that would not think itself disgraced if it had not a tramway and the electric light. The circumstances are different there from those existing here, because they are new towns, and have not had gas introduced; but at the same time there is room for a great business in the future of this particular kind. In England there are 20 such companies, with 127 miles of tram lines, and 1,000 motor-cars, as compared with 1,300 companies possessing 16,000 miles in the United States. It is true that we have 1,700 miles in course of construction, and that is no doubt a very great point. I find that Seattle, in the United States, with a population of 60,000, has 102 miles of tramway, which is a ratio of mileage to population of 1 to 588; Denver has a population of 106,000 and 275 miles of tramway, a ratio of 1 to 720; while Chicago, with a population of 1,098,500, has 513 miles of tramway, a ratio of 1 to 2,141. Now I will give the figures of three towns in our own country. Northampton, with a population of 70,872, has 6 miles of tramway, a ratio of 1 to 11,812; Blackburn, with a population of 120,000, has 8 miles of tramway, a ratio of 1 to 14,125, and Leeds, with a population of 367,000, has 23 miles of tramway, or 1 mile to every 15,978 of the population. Now, with regard to the undertakings in which we are interested. Norwich has a population of 115,000 people, and it will have 20 miles of tramway, a ratio of 1 to 5,700, and Coventry, with a population of 75,000, 10 miles of tramway, a ratio of 1 to 7,500. I think these figures are of interest, and if they come before the public I hope the public will pause and consider what they mean. After providing for the expenses, including office charges and directors' fees, there is a balance of profit of £10,246. To pay the dividend on our 6 per cent. preference shares requires £6,138, which leaves us £4,108 to be carried forward.

The adoption of the report and accounts was then agreed to.

Reservoir Hub and Components Company (Limited).

THE second annual general meeting was held on May 31st, at Mullen's Hotel, Ironmonger Lane, E.C., for the purpose of receiving the directors' report and accounts, which after considerable discussion were adopted. An extraordinary general meeting was afterwards held for the purpose of considering and, if thought fit, passing the following extraordinary resolutions, namely:—"That the Company be wound up voluntarily, as it has been proved to the satisfaction of the Company that the Company cannot, by reason of its liabilities, continue its business, and that it is advisable to wind up the same"; and "That Mr. Arthur Edward Darville, of 28, Basinghall Street, E.C., be and is hereby appointed liquidator to conduct the winding up at a remuneration of 50 guineas." In view of the statement of affairs set forth in the circular to the shareholders dated March 1st last, and the further explanations given by Mr. W. Jeaffreson Woods at the general meeting just concluded, to the effect that although the Company had magnificent prospects they could not go on as they "had not a copper," and although it was suggested that reconstruction might put the Company into a sound position once more, it was finally agreed to adopt the resolution for voluntary winding up, with one dissentient. An endeavour was, however, first made to get the meeting adjourned to arrange a reconstruction scheme if possible, but without success. The chairman stated that the Company's representative was on his way to America, and they had asked £6,000 cash for the American patent, and that under all circumstances voluntary in preference to compulsory liquidation was the best way out of their difficulties.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

Birmingham Manufacturing Company (Limited).—Registered by C. Doubble, 14, Serjeants' Inn, London, E.C.; capital £11,000, in £1 shares. Object, to enter into an agreement with

C. T. Mitchell, and to carry on the business of cycle manufacturers, motor and carriage builders, engineers, &c. The first directors are C. T. Mitchell, E. S. Lermit, W. Davies, and T. Spencer.

British Alcolite (Limited).—Registered by Walker and Rowe, 8, Bucklersbury, E.C.; capital £50,000, in £1 shares. Object, to acquire from David C. Davies the patent rights and benefits of inventions agreed to be bought by him from the Alcolite Syndicate (Limited), to enter into an agreement with the said David C. Davies, and to carry on the business of aluminium and alloy manufacturers and merchants, manufacturers of and dealers in cycles, motors, carriages, and mechanical engineers. The first directors are to be nominated by the subscribers.

British Hydraulic Jointing Company (Limited).—Registered by Maddisons, 1, King's Arms Yard; capital £1,200,000, in £1 shares. Object, to adopt an agreement between E. T. Hooley of the first part, this Company of the second part, and E. Legge, as trustee for and on behalf of this Company, of the third part, for the acquisition of certain patents, patent rights, &c., relating to improvements in the manufacture of tubular joints and frame joints, the jointing of tubular frames, wheel hubs, &c.; to develop, deal with, work, and turn to account the same, and to apply the same to cycle frames, boiler tubes, as builders of motors, general engineers, &c. Registered offices, 9, Pall Mall, S.W.

Challiner and Willoughby Carriage Tyre Company (Limited).—Registered by Burn and Berridge, 11, Old Broad Street; capital £50,000, in £10 shares. Object, to adopt an agreement between the Challiner Tyre Carriage Syndicate (Limited), of the first part, C. Challiner of the second part, and this Company of the third part; and a second agreement between F. S. Willoughby, G. Everatt, G. Hardwick, A. and E. Ramm, H. Hesse, J. Evans, and E. B. Saxby, trading as the Flexible Steel Shod Rubber Company of the first part, F. Willoughby of the second part, and this Company of the third part, and generally to carry on business as ironfounders, mechanical engineers, manufacturers of and dealers in cycles, motors, motor-cars, and the component parts thereof, pneumatic and other tyres, &c. The first directors are:—G. Everatt, W. H. Wilson, F. S. Willoughby, and C. Challiner.

Collins' Patent Lever Gear Company (Scotch Registration).—Capital £2,700, in £1 shares. Object, to adopt an agreement with John M. Collins, engineer, Glasgow, and to acquire inventions for improvements in crank driving mechanism for motor-cars, &c. Registered office, 139, St. Vincent Street, Glasgow.

Drake and Gorham Electric Power and Traction (Pioneer) Syndicate (Limited).—Registered by Ashwell and Co., 79, Queen Street, E.C.; capital £20,000, in £10 shares. Object, to carry on the business of electricians, electrical and mechanical engineers, &c., in all or any of their respective branches.

Falkirk District Motor Company (Limited) (Scotch Registration).—Capital £5,000, in £1 shares. Object, to run motor-cars or self-propelled vehicles for the conveyance of passengers and goods in the United Kingdom and elsewhere. Registered office, 61, High Street, Falkirk.

Kendal Bicycle Company (Limited).—Registered by C. Doubble, 14, Serjeants' Inn, E.C.; capital £20,000, in £1 shares. Object, to carry on the business of cycle and motor manufacturers, carriage builders, engineers, &c. The first directors are:—W. Iliffe, C. J. Cropper, W. H. Sawrey, W. Gaddum, and P. Manning.

Leyland and Birmingham Rubber Company (Limited).—Registered by Jordan and Sons (Limited), 120, Chancery Lane, W.C.; capital £300,000, in £1 shares. Object, to adopt an agreement between the Leyland Rubber Company (Limited), in liquidation, and J. C. Forrester, the liquidator thereof, of the first part and this Company of the second part; and a second agreement between S. Morrison and Co. (Limited) of the first part, A. S. Morrison of the second part, and J. Schutt, as trustee for and on behalf of this Company, of the third part; and a third agreement between R. T. and W. Byrne, trading as the Birmingham Indiarubber Company, of the one part, and J. Schutt, as trustee for and on behalf of this Company of the other part; and, generally, to carry on in all or any of their respective branches the businesses of dealers in indiarubber, asbestos, electricians, electrical engineers, as manufacturers of and dealers in cycles, motors, motor-cars, and the component parts thereof. The first directors are:—J. A. Baxter, A. S. Morrison, R. T. Byrne, J. W. Brown, and S. Whitehead.

Mossberg Roller Bearings (Limited).—Registered by Littledale and Co., 7, King's Bench Walk; capital £80,000, in £1 shares. Object, to adopt an agreement between F. Mossberg of the first part and this Company of the second part; to deal in all manner of articles referred to in Sub-clause A of the said agreement, or any other inventions, for which the Company for the time being may hold; to acquire and turn to account any patents, patent rights, as ironfounders, mechanical engineers, &c. The first directors are:—H. P. Holt, S. Lowe, and E. P. Bainbridge.

Motor-Van Syndicate (Limited).—Registered by M. W. C. Smelt, 5, Lancaster Place, Strand, W.C.; capital £2,000, in £1 shares. Object, to manufacture, sell, experiment on, exploit, repair, let out on hire, and deal in motor-vans, carriages, cycles, wagons, &c., and to enter into a certain agreement. The first directors are:—M. Fairclough, T. C. Palmer, and A. Fairclough. Registered office, 5, Lancaster Place, Strand, W.C.

Porous Accumulator Company (Limited).—Registered by Deacon and Co., 9, Great St. Helen's, E.C.; capital £3,000, in £1 shares. Object, to enter into an agreement with John C. Howell, and to acquire, own, and turn to account an undescribed invention.

Redditch District Electric Traction Company (Limited).—Registered by W. Webb and Co., 37 and 39, Essex Street, Strand, W.C.; capital £2,000, in £10 shares. Object, to carry on business in the manner suggested by the title. Registered office, 37, Waterloo Street, Birmingham.

Werner-Cadmium Electric Accumulator Syndicate (Limited).—Registered by G. Goodman, 21, St. Helen's Place, E.C.; capital £6,000, in £1 shares. Object, to adopt a certain agreement, and to carry on the business of an electric accumulator company.

THE Heilmann Company is about to be reconstituted and additional capital introduced.

MR. J. T. NIBLETT having resigned his position as general manager to the Lithanode Electric Storage Company, begs to notify that he has entered into partnership with Mr. Malcolm Sutherland, and in future the firm will trade under the name of Niblett and Sutherland, Electrical Engineers, 61, Chandos Street, Strand, London, W.C.

MR. ARTHUR F. EVANS, A.M.I.E.E., 107, Wool Exchange, Coleman Street, E.C., has recently been appointed the sole European agent for the well-known "Monarch" petrol engine, which for some time now has done such good work in America. There are several special points about this motor which the makers of the "Monarch" claim as particularly suitable for automotor work. It consumes petrol or any other light oil; it has few working parts; no carburetor, and, therefore, no air regulation valves or other complications. We hope, in a future issue, to give some particulars of this motor after some practical experience with it in motor-vehicle work.

THE LIQUID FUEL COMPANY'S MOTORS.

RECENT IMPROVEMENTS.

IN the latest motors designed and built by this Company for motor-vehicle work are many improvements conducive not only to better running but also to the elimination of that objectionable odour of burning oil which arises in consequence of the lubricating oil getting splashed on hot surfaces. These are shown in the accompanying drawings, of which Fig. 1 is a plan of the general arrangement, and Figs. 2 and 3 side and end elevations.

The oil case, A, is made quite independent of the working cylinders, B, B[1], separating the two from one another by a space, C, open to the atmosphere, but staying the two together by means of distance pieces, C[1]; the piston rods, D, D[1], passing through stuffing boxes in the adjacent covers of both, as seen in Fig. 1. By these means the end, A[1], of the oil case, A, adjacent to the working cylinders, B, B[1], is kept comparatively cool because the steam does not come in contact with it, and consequently any oil that may be splashed on to it is not heated and therefore does not emit an objectionable odour. Furthermore, as there are in this arrangement two stuffing boxes interposed between the working cylinder and the oil case, both of which stuffing boxes are open to the atmosphere, there is no chance of water passing from the working cylinder into the oil case as often happens when the end of the oil case forms the cylinder cover and the piston rod passes through tho same with a single stuffing box.

Another improvement consists in placing the valve chests, E, E^1, in a low position with regard to the cylinders, B, B^1, so as to allow water to drain from the latter into the former, from whence it is taken off into an exhaust box (not shown in the drawings), and thence passes into the exhaust pipe, which is preforably taken from the bottom of the exhaust box. By this means, it is claimed, opening of the drain

Fig. 1.—General Plan.

cocks at starting the engine may be entirely avoided, the water being driven out into the atmosphere, or into the condenser, as the case may be.

Still another improvement relates to the working of the slide valves when, as in the case last referred to for example, the valves are placed low down with reference to the centre line of the working cylinders, so as to be in a lower plane than the centre line and crank-shaft, G. In such case sliding actuating spindles, H, H[1], are used, which are arranged nearly in the same plane as the centre line of the cylinders and crank-shaft, and are operated by eccentrics, I, I[1], in the oil case. These actuating spindles have on them arms, J, J[1], projecting laterally, which are connected with the spindles, K, K[1], of the slide valves, L, L[1], to be operated. When an oil case is used containing the working parts of the engine as thus mentioned, the actuating spindles are arranged to pass through stuffing boxes or guides, M, M[1], in the end, A[1], of the oil case, A. The inner ends of the actuating spindles, H, H[1], are connected, in the oil case, with the link motion, the arms, J, J[1], on the actuating spindles being connected with the slide valve spindles, K, K[1], outside the oil case, A.

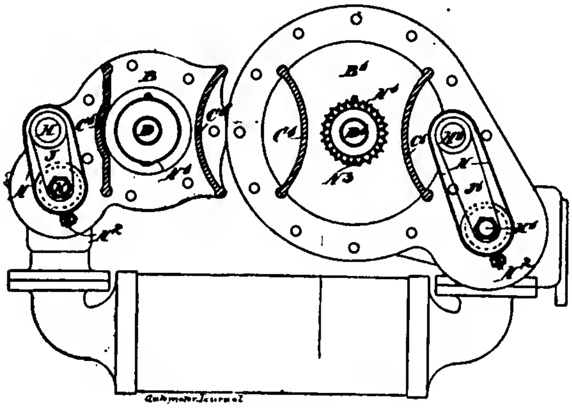

FIG. 3.—FRONT VIEW.

In order to prevent the access of dust to the piston and valve rods where they pass through the open space, C, they are covered with sheet metal covers, N, N[1], passed over the stuffing boxes and secured by means of bolts and nuts passing as shown in connection with the covers, N, or by means of an endless coiled spring, N[3], taking into a circumferential groove, N[4], of the covers as shown.

SERPOLLET'S NEW STEAM CARRIAGE.

By Sir DAVID SALOMONS, Bart.

THE latest form of M. Serpollet's carriage is a distinct advance on anything which has hitherto appeared. The design enables a light steam carriage to be made of a satisfactory character and cheap in price.

The Serpollet boiler may be classed under two heads: one where the tubes are thick and act as accumulators of heat, and the other where the metal is thin and the heat is rapidly absorbed. This latter type is common to almost all boilers which are frequently described as "waterless boilers," and it is mainly in the special construction given to the tubes in which the Serpollet system differs from the others.

In the new light carriage the boiler is of the thin tube type, very small and light in weight. Such a boiler could be sold for 30s., and offer a good profit to the manufacturer, *i.e.*, as soon as an organised factory is brought into existence for its production. The framework of the carriage itself is of aluminium. The working parts consist of three pumps and a steam-engine. The burner employed uses heavy petroleum and does not smoke.

The two new features in the whole system are :—

1. The principle employed for generating steam.
2. A revolution in steam-engine construction.

Starting with number 1 first. The burner is found capable of vaporising six litres of water for the consumption of every litre of petroleum. Therefore, if one pump is employed for forcing water into the boiler, and another for feeding petroleum to the burner, working in a ratio of six to one, both water and petroleum will be fed in the required quantities, and this is the method employed. The arrangement dispenses with air pressure in the petroleum reservoir, and many other complications. A third pump exists for the purpose of carrying the water from the condenser back to the reservoir. These three pumps work on one shaft, and the strokes of the petroleum and water injection pumps can be varied, but always bear the proportion one to the other indicated. It will, therefore, be gathered that when less steam is required, and the throw of the injection pump is diminished, the burners are at the same time fed with less petroleum. Hence from zero to maximum power the water and petroleum supplies are automatic, and in correct proportion one to the other. When the pumps are doing no work the burner is not extinguished, but is then fed by means of a pass-bye cock.

Let us now consider number 2. In the new engine all the vexations to be found in the ordinary form of steam engine, and which are present in almost every kind of motor, are absent, viz., joints and complex valve gear. The engine is made as follows :—Two cylinders are placed in a line but working opposite to one another, so that the cranks are between them and contained in a box. The whole of the working parts therefore are enclosed. The steam acts only behind each piston; it will therefore be observed that no joints under pressure exist, for the only two are those where the cylinders are joined to the crank box, and these are not under pressure. The oil contained in the crank box is splashed by the revolving crank and greases the cylinder as well as the crank.

On the top of each cylinder is a little valve actuated by a rod, and is worked to and fro through the distance of about half an inch by means of a cam. These are the two valves which admit steam into the two cylinders alternately. The cam is so made that, by shifting it, the direction of the motor is reversed. In fact the admission of steam to the cylinders is identical with the method employed for admitting gas to a gas-engine. The cut-off is about one-fifth of the stroke, and no special exhaust valve is required. It is simply the piston which uncovers the opening. It might be urged that, since on each return of the piston a certain quantity of steam is compressed, power is lost, but because the steam admitted is superheated there is no loss whatever, as a regenerative action comes about. In point of fact, these engines, for a given size of boiler, raise the power of such boiler two-fold. The water which is pumped from the condenser back into the reservoir passes through sponges, which absorb the oil which might come from the cylinder. The condenser itself is cleaned by passing a jet of steam through the tubes, which operation is effected by merely turning a tap when steam is in the boiler.

To start the carriage the usual pump lever is moved by the driver, actuating at the same time all three pumps. Two or three movements and the carriage is started, then all is automatic.

There is a total absence of the complex tubing to be found in general in motor-carriages; this in itself is a great improvement. The small carriage that I saw was the first experimental one, but its success is such that it is serving as a pattern for the construction of six others. The little carriage could be lifted from the ground by M. Serpollet and myself without any undue effort. The H.P. was nominally 3, but capable of giving double this power for short periods.

At the present time the steam-carriage suffers a disadvantage compared with gas motor-carriages, because the latter have received attention for a longer period, and organised factories exist for their construction. Even now there is no organised factory turning out light steam-carriages.

To the majority of people it would appear extraordinary that M. Serpollet's French Company should not have turned their attention in this direction, but only those behind the scenes know the true reasons, which are, that in early days, alliances were made with various companies which have rather retarded than accelerated manufacture on a large scale. In the next place, enormous orders for tramways on the Serpollet system have come in, that the attention of all those interested was completely absorbed in turning out the cars till within quite a recent date.

It is understood that very shortly the manufacture of light steam-carriages will be seriously entered upon in England, numerous experiments having been undertaken for some time past at a large and well-known English factory.

It is my own opinion that if the new light steam-carriage, which is in the form of a dog-cart, is made in any quantities, say 12 at a time in an organised factory that they could be sold for £80 apiece and perhaps less. At such a price they would be a boon to those who live in the country and require a carriage of some kind, where the present cost of a horse presses somewhat heavily upon their purses, and the price asked for oil motor-carriages is out of the question for this class of people.

Finally, the fatigue experienced when riding in oil-driven carriages is quite absent when steam is employed for motive power.

BEESTON MOTOR COMPANY.

The employés of the Beeston Motor Company (Limited) assembled for their first annual dinner last month at the King's Head Hotel, Coventry.

The chair was taken by Dr. C. W. Iliffe, who was supported by Messrs. Rowland Hill (chairman of the Company), S. Gorton (managing director), Dr. Roberts (St. Albans), A. Clay (cashier), and W. Taylor (works manager).

Dr. Roberts, in submitting the toast of "The Beeston Motor Company," said he thought he was the first medical man to have taken up motor tricycling. He was doing his utmost to get medical men all over England to take it up, because he believed it the finest thing they could possibly have to assist them in the discharge of their duties.

Mr. R. Hill, responding, thanked Dr. Roberts, who, he said, was not only the first medical man having experience of their motor cycles, but he had been good enough to assist them by giving his experience to the Press and the world in general. As the result of an interesting letter in the *Lancet* Dr. Roberts had received no less than 250 letters from the medical men of England, making inquiries as to the motor tricycle.

Mr. S. Gorton also responded, and said in this country new inventions had always been more or less subject to ridicule. When Stephenson built his first engine, "The Rocket," sometime about the year 1829, to run upon rails, he was ridiculed all over the country. But he put up with the ridicule, and it did not deter him at all. What was the result? To-day the world was covered with a network of railways. Then came the introduction of the ordinary bicycle, and that suffered the same fate, as regarded ridicule, as the railway had. Yet what was the position to-day? Why, all the world was on wheels.

Mr. Taylor, called upon for a few words, gave the workmen some sound practical advice, urging patience in mastering this new industry.

THE MOTOR-CAR CLUB.

An "omnibus meeting," promoted by the Motor-Car Club, took place on the 8th inst., the object being to demonstrate the attractions and advantages of motor omnibuses and cabs. There was a large assemblage of visitors at the Hotel Métropole, lunch being served in the Whitehall banqueting room, prior to the experimental runs. Mr. Sydney Gedge, M.P., presided, and among the company were: Lord Crawshaw, Mr. Harry J. Lawson (president of the Motor-Car Club), Sir Charles Hartopp, Col. Josiah Harris, Sir H. H. Bemrose, M.P., Mr. D. Crilly, M.P., Mr. Henniker Heaton, M.P., Mr. Geo. H. Little (The Automotor), Dr. Clarke, M.P., Mr. Guy Pim, M.P., Mr. A. Arnold, M.P., Mr. Beresford Melville, M.P., Mr. F. W. Lawrence, M.P., Mr. E. Parker, M.P., Mr. H. A. House, jun., Mr. George Iden, Mr. Thomas Robinson, Mr. J. H. Mace, Mr. E. M. C. Instone, Mr. Baron (Blackpool Motor Company), Mr. Fleming Nesbitt, &c.

The Chairman proposed "The Queen," and expressed a hope that Her Majesty would see as great a change in the matter of locomotion at the end of her reign as she did at the beginning on the development of steam traction.

In proposing "The Motor Club," the Chairman said those engaged in the manufacture of motor-cars summed up their merits by declaring they would "go anywhere and do anything." If they would do only half what was claimed for them they would certainly meet a great public want, and the advantages to the community, directly and indirectly, would be immense.

Mr. Harry J. Lawson, with whose name the toast was coupled, said:—The object of to-day's meeting is to show a number of colonists and other visitors to London what progress is being made in machine traffic, more especially the Petroleumnibus—as it has been christened by a daily paper, for which we are much obliged—but which, to abbreviate it to the first and last syllables, we will term the Pot Bus, or Favourite. The omnibus is the carriage of the people, and in this sense this occasion is interesting to the public of the whole world. If you go outside and see a bus that will carry you farther for one penny and faster for one penny than any other, that bus is going to have the public penny. It is 18 months since the Act of Parliament was passed permitting motor-cars on the road, but only about 12 months since the first British-made motor-cars appeared in the streets. Now, however, every day they are becoming more and more familiar spectacles. What I want you to see to-day is the first machine omnibus that is driven by petroleum. Further, I shall show you to-day a machine traffic cheaper than the cheapest light railway, because it has no railway at all. If the tramcars can be made to work carrying the same number of people equally well without the public nuisance of tram rails, surely it is a matter demanding the attention of the Government at this time, and especially the London County Council, who will be wasting millions of public money by purchasing a road which is superseded. Under these circumstances should we not impartially inquire what the facts really are? In Paris the Government has satisfied itself, by independent inspection, of the advantages of the motor and steam omnibus and machine traffic of all kinds, both in the Army and in the Post Office, and now decides to take the proper step by granting Government subsidies and Government help by money grants to assist manufacturers in immediately developing to the advantage of all this great industry. I want to-day to put this thing on altogether a different platform. This is no matter for private enterprise merely. Towns in England and the colonies are existing to-day without any means of machine transport; and when we look at a place like India, with lovely, flat, level roads, hundreds of miles at a stretch, I say the Government of to-day is losing an immense hold it might have upon the natives and inhabitants of that country by giving them an easy and cheap means of transport. You often hear people say these vehicles seem to work very nicely; but how is it there are not more of them on the road? Well, on this I would point out that there are 16,000 traction engines licensed in the United Kingdom, and how often do you see a traction engine? I will now give you the result of a test as to the Pet Bus. One was put on the road at Regent Circus at eight o'clock on Monday morning, and was run to Ealing. I compare it with the system of the London General Omnibus Company, which has a very efficient service of horse omnibuses, and these are the facts:—Official chartered accountants sat on our bus and measured the petroleum, and two official handicappers clocked for stoppages. The number of journeys we did was seven return journeys—that is to say, 98 miles during the day. We left off at 11 o'clock p.m. The London General kept on until 12 o'clock and did five journeys, using 14 horses including extra animals at two hills on the road, and covered altogether 70 miles. Then, I should mention that we allowed people to get on our car free, and the consequence was we had a great crowd and heavy loads to carry, but that made no difference to the engine. On these conditions the maximum takings of the London General bus would be £6 5*s.*; ours would be £8 5*s.*, and the cost per journey for petroleum would be 5½*d.*; the accountants certified that 13 gallons were used during the day, the cost being 5½*d.* per gallon. The cost of bus washing with the London General would be 6*d.*, as compared with perhaps 9*d.* in our case; but then we should have no stable grooming to pay for, and there would be no eating of food all night in our case, and no harness expenses, shoeing, or veterinary charges. Then I notice that the London General paid £53,644 in six months for horse renewals, against which all we should have to do would be to put in new brasses or new piston rings when the bearings or other parts wore out. In concluding, Mr. Lawson expressed a hope that the Press would help forward the industry, remarking that it had great power of performing a useful office to the public in doing so.

A number of vehicles of various descriptions were drawn up at the door of the hotel in Whitehall Place, and most of the company were taken on short trips along the Embankment to Westminster or Blackfriars. The vehicles included the celebrated "Lifu" No. 1, in charge of Mr. H. A. House (illustrated in our present number); a Weidknecht steam omnibus; a 10 H.P. Daimler (German make) omnibus with serrated tyres, which, by the way, are illegal; and several Panhard and Levassor, Daimler, and other voitures, most of which have already been illustrated in the pages of The Automotor. All these ran excellently and without any manifestation in the shape of noise or smell. In the newer types of oil vehicles vibration was hardly perceptible. There was no smoke and no steam. The police, who maintained excellent order, seemed very much impressed with the speed, quietness, and perfect manœuvring powers possessed by these vehicles, which were one and all most skilfully handled. If, instead of this being a motor-vehicle meet, it had been a coaching club meet, the street would have resembled a foul-smelling stable from the large quantity of fœcal matter that the horses would have ejected, and the services of the street orderly boys would have been requisitioned to clear away the offensive matter. After this motor-vehicle meet the street in front of the Whitehall Rooms was as clean as ever, save for a few drops of lubricating oil here and there; but on the cab ranks were piles of filthy horse manure, around which stood and gossiped those real old Tories, the London cabmen—impotently cursing the motor-vehicle.

NAUTICAL AUTOMOBILISM.

A Daimler Launch.

One of the purposes to which a good oil motor lends itself is the propulsion of vessels such as launches, yachts, and such small craft, up to, say, fishing trawlers. In the latter, oil motors up to 90 H.P. are most successfully applied. The Daimler Company have for some time past made a speciality of launches intended for river service and as tenders to large yachts. Their most recently acquired vessel of this description is a handsome launch, 56′ 0″ × 9′ 6″ × 4′ 9″, designed by Messrs. J. and H. Paterson, naval architects, Greenock, and built by Messrs. Paul Jones and Son, of Gourock, for the Daimler Company, who intend to follow the various yacht races and regattas round the coast, so as to demonstrate to yachtsmen and others the merits of this system of oil propulsion. Needless to say, the vessel is beautifully fitted with every appliance for safety and comfort. She is propelled by a gun-metal three-bladed propeller driven by two 10 H.P. Daimler motors coupled together, thus giving an impulse every revolution. After a most satisfactory trial trip she was taken round from Greenock to London, and the following is a log of the run supplied to us by Mr. A. H. Deaville Altree, the general manager of the Daimler Company:—

Log of the Launch "Daimler," from Greenock to London.

May 11th, 1898.—Left Greenock 12.30 p.m.; strong north-west gale and heavy sea; entered Bowling Canal 2 p.m.; passed cutter yacht "Rosette," towing through canal and bound for London. 9.30 p.m. moored at Wyndford, 26 miles from Bowling and 10 from Grangemouth, where canal ends. This waterway is 36 miles long, and has 40 locks, 16 of them being in the last 1½ miles. The cargo steamers using the canal usually take 13 hours in transit from end to end.

May 12th, 5 a.m.—On rising, discovered the decks coated with ice, and that a heavy snow had fallen on the hills during the night. Arrived in Grangemouth 9.20 a.m., and partook of a very welcome breakfast. Left Grangemouth 10.30 a.m. on the ebb tide, with fresh north-west breeze, passing under the Forth Bridge at 12 noon, and at 1.25 p.m. moored in the Yacht Basin at Granton Harbour to obtain water. Hail and snow squalls were frequent, with very strong breeze, the storm cone being hoisted, and the harbour master reported that outside the Firth a heavy north-east gale was blowing. He strongly advised us to remain in shelter till the following morning, at least.

May 13th.—Turned out 4.10 a.m. Got dinghy aboard and made everything fast, in case heavy weather should be encountered outside. Hove up anchor 6 a.m., the wind in the Firth being W.N.W., and the day fine though hazy. Outside found heavy swell rolling from the north-east, but the launch behaved grandly. 2.45 p.m. passed inside the Farne Islands, and at 7.45 p.m. moored in Blyth Harbour, 7 miles north of Shields, the day's run being 103 knots, as registered by Walker's "Harpoon" log. No water was obtainable, and our supply being extremely limited, our ablutions on the following day were naturally somewhat restricted.

May 14th.—4.45 a.m. got under way, the easterly haze and heavy swell still continuing. Passed Whitby 11 a.m., and moored in Grimsby Harbour 9.40 p.m., the day's run being 133 knots. Fresh stores were here taken aboard to cover our needs until Monday morning.

Sunday, May 15th.—Having taken the opportunity of getting rather more sleep than we had been having, we did not leave Grimsby until 8.25 a.m., and for the first time during the run had really fine weather all day, the swell having gone down to a great extent. Lowestoft Harbour was reached at 9.45 p.m., the distance run being 109 nautical miles, and we moored alongside a fishing lugger, the solitary man on board explaining to us that his mate had gone ashore for a "hurst." Perhaps this accounted for the extraordinary interest he displayed in all our proceedings, his attention being particularly absorbing while I endeavoured to straighten a small nail with a large hammer.

May 16th.—Left Lowestoft 7.25 a.m., and put into Harwich at 1.20 p.m. to unload empty cans and cases which had contained our rectified petroleum, leaving for the Thames an hour later.

When three miles off Harwich I decided to try the benefits of a (very) cold bath at the end of a bowline, and as the launch was under fore and aft canvas, the engines were reversed to stop her way. This was all right until the attempt was made to get on board, and at the same time keep clear of the propeller; but the difficulty was finally solved by the skipper and cook hauling me on board by a leg and an arm. As the skipper had just been engaged in brass work cleaning, I came out of the ordeal looking very much like a Dalmatian dog. On reaching Shoeburyness the launch was timed over the measured Admiralty nautical mile on the last of the flood, the distance being run in 5m. 56s., a shade better than 10 knots. Moored off Southend at 6.55 p.m., the day's run being 73 nautical miles.

Next morning matters were taken in a rather more leisurely manner, the trip concluding on our arrival at Grays, where our mooring berth was to be. Throughout the whole of the run no discomfort was experienced, except when the deck hand, in washing down early on the last morning, hove the greater part of a bucket of water through the open port, effectually disturbing my slumbers.

Towage on Canals.

The success attending an application of electric towing on the Burgundy Canal was such that two new applications of electricity to canal haulage, and also for barge propulsion, were made last year in the neighbourhood of Dijon on the same canal, under the superintendence of M. Gaillot, Ingénieur des Ponts et Chaussées. In the method of haulage the receptor dynamo is mounted on a tricycle, to which the name of "electric horse" has been given, and which, running on the towing path, takes its current from an air line consisting of two wires, mounted 5 metres (nearly 17 feet) above the surface. This "horse," which weighs 2 tons, and is guided by a driver mounted upon it through the front wheel, proceeds on the towing path like a traction engine; and the boats are connected with it by a rope, with automatic disengaging gear, in case the force of the stream or a gust of wind should drive a boat backwards. Speeds of from 1,990 to 4,240 metres (mean 3,319 yards) were obtained with the electric horse, towing from three to four boats, so that it is more suitable than the electric propeller for towage in rivers or very long reaches; but it requires a driver, while the propeller, with which speeds of from 2,150 to 4,240 metres (mean 3,406 yards) per hour were obtained, is worked by the bargee on board his boat. The towing path is not worn, and there is no occasion for a tow rope, which always causes difficulty when two boats cross one another. M. Maillet and M. Dufourny, Belgian Ingénieurs des Ponts et Chaussées, who watched the trials, conclude that a practical solution of the question depends upon the cost of producing the motive power; but they also consider that horse haulage on canals will soon be superseded by mechanical traction, based on the use of an automotive tricycle, working with petroleum or some other hydrocarbon, and capable of running on the tow path without requiring any fixed plant.—*Engineer.*

An important experiment is about to be made on the Western of France Railway. This Company has decided to provide passengers at the Paris terminus with electric carriages. As at the Saint-Lazare Station there is electric plant, the entire output of which is available during the greater part of the day, the Company proposes to utilise this to charge the accumulators of the cabs in question. The Company has applied to motor-car builders to provide a type of electric-car to carry four passengers and 331 lbs. of luggage, capable of running with safety 31 miles per day. The Company will take these cars for a trial of six months at a rate of pay per day to be fixed, and at the end of this time reserves the right to make a choice and purchase, at a previously fixed price, the vehicles which have taken part in the competition.

FOREIGN NOTES.

The Automobile Club de France has a membership of 1,430.

A service of steam omnibuses is to be established at Doubs, between Salens and Be ançon.

Paris is to have a Metropolitan Railway; the Company is to have a capital of 25,000,000 francs.

La Société Européeno d'Automobiles has been registered at Brussels with a capital of £22,000.

MM. De Dion and Bouton are constructing a number of steam-omnibuses for a public service between Lavaur and Grauthet. The route is about 12 miles long.

It is said that the patent rights for England in the Roser and Mosurier motor have been sold to an English company for a very large sum.

Referring to the deplorable accident at Périgueux whereby the Marquis of Montagnac lost his life, it seems that at the time of the accident he was going at a speed of 17 miles per hour.

A new motor-vehicle club is in course of formation at Nymwegen, in Holland. The chief members are Messrs. Meer, Kueppers, Wendelaar, Houwink, Aertuys, Baron Wassenaar Hegge-Zynen, and Du Moulin.

In Switzerland the speed of street vehicles is strictly limited by law. Tramcars in towns must not exceed 7 miles per hour, and in the villages 9 miles per hour. Outside the towns the speed may be 11 miles per hour, and in the open country 15 miles per hour.

La Chambre Syndicate de l'Automobile has been formed recently with an active membership limited to 30. The President is the Comte de Dion, with MM. Panhard and Jeutcaud as Vice-Presidents, and M. Thériu as Secretary.

M. Ernest Bollée, the well-known constructor, has been nominated deputy for the department of Mans. In our House of Commons there is not a single member that can be said to represent the technical branch of automobilism.

As showing the hold that automobilism has in France upon the electorate, M. Francois, the proposer of the tax upon automobiles, has been rejected by his constituents, and is now replaced in the Assembly by M. Castellane, a practical automobilist.

The Great Western Railway of France (it could not possibly be our own benighted line with a similar title) is not only using various types of oil motor-vehicles, but is considering the question of electric vehicles for its country services.

So busy are the makers of motor-vehicles that it is very difficult to obtain delivery of orders. At Mantes a Tenting oil-motor omnibus had been ordered some months ago but has not yet been delivered, and the local authorities have had a warm discussion about it.

Steps to check motor-scorching in Paris have at length been taken by the Prefect of Police, and not before it was necessary. Not only have motor-vehicles now to carry a number-plate, but the speed is to be strictly limited to 12 miles per hour. The speed is quite sufficient for all practical purposes wherever there is any traffic. Even visitors coming to Paris for a temporary stay will be required to procure an official number on passing the barrier. We resent as much as anyone anything like grandmotherly legislation, but the excessive speed that many automobilists permit themselves to indulge in constitutes not only a danger but a nuisance, which, if anything, is worse.

Folding chainless bicycles are used by the French army, weighing about 28 lbs. They are made with drop frames so that the soldiers can stand in firing position between the wheels. Tandems and triplets are also in use, their advantage being that the loss of a rider does not involve the loss of a machine.

Another serious accident has occurred in connection with the motor-vehicle races which have such a charm for our French neighbours, but happily without loss of life. It appears that during the Paris-Bordeaux race when near Agoulême, M. Mors, the well-known constructor, while proceeding on his machine at a rather rapid rate, had to swerve to the right in order to avoid a horse that had shied, in so doing he collided with a tree, with the result that M. Mors was thrown out and broke his collar-bone. He is, however, recovering.

In the "Criterium des Entraineurs," organised by our contemporary, *le Vélo*, and which was held last month just as we were going to press, there were 40 competitors; the route was from Paris to Bordeaux. The winner was M. R. de Knyff, the second place was gained by M. Charron, and the third by M. Brenil. All three rode Panhard and Levassor voitures. The fastest time, that by M. Knyff, was 15 h. 15 m. 44 s., and the distance 223 miles. In the second class, which comprised vehicles weighing less than 400 kilogrammes, the winner was M. Corre in 18 h. 30 m. 10 s.

The Préfet of Police at Paris has appointed a Commission to study the question of the speed of motor-vehicles in the streets, and MM. De Dion and Gamard have been appointed as delegates from the Automobile Club. It is rather significant that this Club has issued a circular in which automobilists are requested to moderate their speed. In this the Club is acting, we think, wisely, as that body can exercise considerable influence with its members, and it is better that voluntary action rather than legal obligation should determine this speed question.

The higher clergy in France find a motor-vehicle a convenient means for visiting their dioceses. Thus Monseigneur the Cardinal Lecot, who has taken a great interest in automobilism, is making a pastoral visitation on a motor-vehicle belonging to M. Journier. Our English bishops might, with advantage to themselves and their flocks, imitate this excellent example. Nothing in the way of travelling is more delightful than to go through the country at this time of the year on a well-appointed motor-vehicle. One arrives at the end of a journey fresh and ready for work, whereas a long railway journey or a coach journey exhausts one terribly.

The French army authorities entertain a high opinion of the value of motor-vehicles for certain military purposes. Captain Barisien, of the 4th Regiment, stationed at Grenoble, and one of the officers selected by the War Office to attend Les Poids Lourds trials last year, has lately been through a course of military manœuvres with his regiment. These took place in very difficult country, but he attended them with his 4 H.P. Peugeot, and in all the various operations the motor-vehicle was most successful, traversing a mountainous region with bad roads in a most remarkable manner. His superiors were much pleased with the results of this very searching ordeal. Beyond a few obsolete and enormously heavy traction engines the British army does not possess a single automobile vehicle.

The indignation that has been aroused in Paris through the dangerous speed at which many motor-vehicles are driven has taken some curious forms of expression. Thus a good many persons, whose lives have been risked by this reckless driving, have announced their intention of carrying revolvers, for the purpose of stopping the senseless automobilists, who, like our cycle scorchers, are so indifferent to the comfort, not to say the lives, of their fellow-creatures. While not endorsing the revolver cure, we sympathise with it to a certain extent, because a fast motor-vehicle will be out of sight and many miles away before even a telegram can be despatched to stop it. The injured party has little or no chance of identifying the person who knocked him down. Hence a good deal can be said in favour of the bullet. Such methods are, of course, foreign to our ideas of legal action, and are altogether barbarous. A better way is to trust to a careful police patrol and the infliction of adequate punishment. We suggest for a repeated offence confiscation of the vehicle, its immediate sale by the authorities, and the proceeds to go to the hospitals.

SELF-PROPELLED TRAFFIC ASSOCIATION

(INCORPORATED).

LIVERPOOL CENTRE.

AT a council meeting of the Liverpool Centre, held on Friday the 10th instant, the annual general meeting of this branch was fixed to be held on Tuesday, July 12th, at 4.30 p.m., in the hall of the Chamber of Commerce, Exchange Buildings, Liverpool. The business to be transacted at this meeting will be—

(*a*) To adopt the report of the council on the second session.
(*b*) To elect members of the council to hold office for a period of two years.

A COMPLETE list of guests and full report of the speeches in connection with the banquet which took place on May 26th at the Adelphi Hotel, Liverpool, in connection with the Heavy Trials have been printed in pamphlet form, and copies may be had from the Hon. Organising Secretary, Mr. E. Shrapnell Smith, at 3*d*. each, post free.

PHOTOGRAPHS of the "Meet" of the motor-vehicles in connection with the Liverpool Heavy Trials, taken at Aughton on Tuesday morning the 24th May, can be obtained from the Hon. Organising Secretary, Mr. E. Shrapnell Smith, on the payment of 3*s*. 6*d*. per copy, including package and postage. Mr. Shrapnell Smith's address is Royal Institution, Colquitt Street, Liverpool.

LIGHT OIL MOTORS.

By JOHN HENRY KNIGHT.

THERE are only two oil motor-cars, that is petroleum oil-motors, used for road work in England, that have come under my notice, these are the Roots and the Petter; both use the ordinary paraffin or lamp oil. All the others, the Daimlers, the Benz, the Mors, the Bollée, and De Dion tricycle, use a light oil, giving off vapour below 73° F., and by Act of Parliament called potroleum.

There are various brands of this light oil; gasoline, which is probably the lightest, has a specific gravity of ·66, it is largely used in America for carburetting air for use as a gas for lighting houses, and some 20 years ago many country houses and churches in England were so lighted. Benzoline, petrol, petroleum spirit, and the French "Essence de Petrol" are various names for this light oil, the specific gravity of which should not exceed ·70. It seems unfortunate that these petroleum-engines should ever be spoken of as oil-engines, that term being legitimately applied to the heavy oil-engine. Light petroleum has very little of an oily nature. Every one knows how benzoline is used for removing grease spots and oil stains from clothes.

There are several advantages in using petroleum spirit in motor-cars in place of the heavy lamp oil:—(1) It does not give out the disagreeable smell that oil does; (2) being less rich in carbon there is no smoke from the exhaust and altogether it is more cleanly to work; (3) the engine is more easily started, there being no vaporiser to heat up.

It has the following disadvantages:—(1) Its price is nearly three times that of oil. (2) It being more inflammable and consequently dangerous, its sale and storage are regulated by Act of Parliament. It, unlike paraffin oil, cannot be obtained in every town or village. (3) In damp weather it is difficult to get the air to absorb or take up the proper quantity owing to the air being saturated with aqueous vapour. Most owners of motor-cars must have noticed how at times the engine runs better than at others, this is often due to the dampness of the air. Heating the air, as in the Daimler, makes matters better, but it does not remove the water vapour. To do this the best way would be to pass the air through some substance that will absorb water, such as calcium chloride or even lime. Many years ago I used lime to dry the air for a gasoline gas machine. The experiment was partially successful; with a better arrangement of lime it would doubtless have answered well; the passage where the air passed the lime was too short—it should have been much longer. Of course, it would have to be shown that the gain in power would be worth the extra weight to be carried and the cost of the lime, but it seems that the experiment is worth trying.

Of carburettors the early forms using cotton wicks or wire gauze to present a large moistened surface to the air have been discarded. The automatic spray-making, on the bird-fountain principle, by which the right quantity of petroleum is sucked into the cylinder as spray, is used on the Daimler and one or two other types.

Another form, used on the Benz and on De Dion tricycles, is air impinging vertically on the surface of the petroleum. My experience has been chiefly with this form of carburettor.

In all these fast-running engines the pipes for air and petroleum vapour must be much larger than in the slow-running stationary gas-engine; the exhaust valve should be so fitted that it should be full open before the out centre is reached. I believe there are many motor-cars that could be improved by a careful resetting of the values.

Tube ignition has much to commend it; the greatest objection seems to be the danger of fire in case of an upset. Sometimes the wind will cause the lamps to be extinguished, or it will blow the flame away from the tube, which quickly cools down. I have given tube ignition and electricity a fair trial on my car, and in my opinion electricity is the best.

As regards electrical firing in two different cases that have come under my notice, the power of the engine was increased by substituting tube ignition for the electric spark, the reason being that the electrical firing was not soon enough, and an indicator card taken from either of these engines would have shown a "camel-backed" diagram due to late firing. If, however, the firing cam or contact piece is early enough to give a full diagram, electrical contact must be made when the crank is 45° from the centre; that is with a fast-running engine. Now, to start such an engine by hand would be difficult, if not dangerous, as the engine would fly back before the centre be reached. To obviate this, some cars are fitted with an arrangement to alter the position of the firing point while the engine is running; for startiug it is placed uear the centre and worked forward as the speed increases. This method was first nsed by Messrs. Priestman, of Hull, in the small oil-engines they make for marine purposes.

Some motor-vehiole owners complain of trouble with electrical ignition. The trouble may arise from several causes—to too great distance between the sparking points in the cylinder. It must be remembered that a coil which will give an inch spark at atmospheric pressure will give a very much shorter one in the compressed mixtnre; besides, for quickly firing the charge a fat or flaming spark is necessary.

Soot on the insulating plug should be wiped off; a crack in the porcelain will allow the spark to pass without going into the cylinder. It might be possible to cement this with silicate of soda, but the best way would be to pnt in a spare plug; it is needless to say that a spare plug should always be carried.

Sometimes it happens that the coil will stop working, the platinum contact points becoming rough. If they are carefully examined it will be noticed that one is pittied and the other has slight nodules raised on it, these should be rubbed down with a fine file or a piece of emery cloth; but the vibration of the car appears to assist in keeping the contact spring in vibration.

As regards the porcelain insulations, there is naturally a difficulty in keeping these tight on account of the difference in the expanding ratios of iron and porcelain, so that if compression is lost it would be one of the first places to look for leakage. The best method of searching for air leaks is to wet the suspected part with soap and water with a brush or piece of waste, the outcoming air forms soap bubbles and the leak is at once detected. It is best to use soft soap and rain water, for it is sometimes difficult to get a lather with hard water.

Lubrication of the piston is a most important point and there is no economy in attempting to save oil in this respect. In one of my early oil-engines, the first two or three days of trial the engine would only run for a short time and then would pull up—the expansion of the piston in the water-jacketed cylinder causing it to jam, and it was necessary to replace the piston in the lathe and very slightly reduce its diameter. In small motor-car engines the diameter of cylinder being so great in proportion to area, it is quite possible that something of this sort may happen, not, of course, to actually stop the engine, but the extra friction may materially reduce the power.

Another source of loss of power is leakage. If the piston and its rings are properly fitted at first the engine should run for a long time without requiring the rings to be renewed. With old oil or gas engines, when the cylinder becomes by wear slightly oval, there is difficulty in keeping the piston tight with even new rings, and the same difficulty will occur in motor-car engines, bnt many of these engines have steel liners for the cylinder bore, which cannot be expensive to renew.

Other sources of leakage are the valves, exhaust and suction, the joints of the valve castings and cylinder cover, and the igniter. The exhaust valves may possibly at times require grinding in; the suction valve should run for years without anything being done to it, but I have seen a suctiou valve that was not true with its stem, whether the valve stem had been bent or it had been thus sent out by the maker it was difficult to say, but it was a source of annoyance.

In case a joint should blow when on the road, spare asbestos flanges should always be carried. If any particular joint continually gives trouble, a good plan is to soak the asbestos card in soluble glass (silicate of soda), or in shellac varnish. In this case it is best to give the joint some time to set before using the engine. Litharge and glycerine have been recommended for petroleum joints.

Accumulators are sometimes a source of trouble. Some of those imported from the Continent have, doubtless, not been so durable as they should be; the E.P.S. cells appear to answer well. It seems to be best to partially recharge the cells every evening, that is if the car has been in use during the day. This prevents the chance of disappointment by a cell running down unexpectedly.

In conclusion, there is still a good deal to be learnt by each motor-vehicle owner; each type of engine, and almost each engine, has its own peculiarities; a good deal might be, and doubtless is, learnt by each owner talking over with others the difficulties and pointing out the good qualities he has discovered in his motor.

Everything should be kept in order and repair; a bearing left untightened may cause the bolts to snap and the crank-shaft to break. Railway locomotive drivers can tell by car how the engine is running. So should the motor-car driver; he should carefully note any change in the beat of the machinery, and by stopping in time a serious breakdown may be averted.

CORRESPONDENCE.

*** We do not hold ourselves responsible for opinions expressed by our Correspondents.*

*** The name and address of the writer (not necessarily for publication) MUST in all cases accompany letters intended for insertion or containing queries.*

*** Correspondents are particularly requested to write on one side of the paper ONLY, to place the subject of their letters as a headline at the top of the sheet, and their names and addresses at the foot. Attention to these matters saves much time and ensures the insertion of the letter.*

THE BRITISH MOTOR SYNDICATE.

To the Editor of The Automotor.

Sir,—I must contradict the information you seem to have got that the British Motor Syndicate has settled with the shareholders. They may have done so with some, and if so, and that those some have made a special settlement on terms of its being kept private from the others, I think those others have a good case, not only against the Syndicate, but against those some, and from communications I have had with others left out so far like myself, I think we will make it hot for the Syndicate yet.—Yours, &c., T. G.

County Kildare, *June 6th*, 1898.

[We refer to this matter elsewhere.—Ed.]

We have pleasure in publishing the following letter:—

THE CARRIAGE OF PETROL.

Andrew W. Barr, Esq.,
Self-Propelled Traffic Association,
30, Moorgate Street.

Sir,—Replying to your letter of the 1st inst., asking us to tell you the result of our negotiations with the railway companies for the carriage of petrol, we are glad to inform you that the railway companies have agreed that petroleum ether or petrol shall, as from the 1st inst., be carried at the third class rates if packed in hermetically sealed tins or bottles enclosed in cases, each package not exceeding 84 lbs. in weight, with a minimum charge of 5*s.* per consignment. The effect of this is that petrol (petroleum ether) can now be sent in small quantities at a reasonable charge for railway carriage instead of at the almost prohibitive rates which the railway companies for a long time were desirous of insisting upon.

This satisfactory result has been brought about after very lengthened negotiations which began in November, 1896, at the time when the Locomotives on Highways Act was passed.

As soon as that Act became law we pointed out to the railway companies that there was almost certain in the near future to spring up a good demand for petrol, the special kind of doubly distilled petroleum spirit, which had been found most suitable for the motors of auto-cars. We represented that it was essential to the development of the industry that this fuel should be carried by the railway companies in small quantities at a reasonable rate, all proper precautions having been taken to ensure its safety in transit.

Although several of the principal railway companies assured us of their sympathy, and promised to put in force as low a rate as possible, after several months' negotiations we were told that petrol or motor-car spirit had been put in the classification under the fifth class.

We at once recognised that to pay these fifth class rates on petrol would be fatal, and if nothing could be done to meet the difficulty, a serious blow would be inflicted on the rising auto-car industry. We then found, after studying the Railway Classification of Rates book, that ether could be sent at the third class rates under special conditions. Now, petrol is a kind of ether, and we at once decided to comply with the special conditions, so as to avail ourselves of the cheaper rates.

But this was not the end of our difficulties, for having gone to very considerable expense, and having spent over £500 in providing packages to comply with the special conditions, we were told it was of no use, because petrol was not ether, and therefore we had no right to describe it as such.

However, we were able to show that petrol complied with the specification given for petroleum ether in the British Pharmacopœia, which is the highest authority on such matters.

As a rejoinder to this, in January last, we were officially informed that the classification of ether was to be altered so that it should only apply to sulphuric ether.

We then said if this were carried into effect a great injustice would be done us and a serious blow would be inflicted on all persons interested in automobilism in this country. A great injustice would be done us because, on the strength of the classification, we had spent a considerable sum of money in providing the special packages necessary to comply with it, and, moreover, there were three good reasons why petroleum ether should be carried on at least as favourable terms as sulphuric ether, viz.:—(1) It was a safer article to handle. (2) It was considerably lower in price and therefore could not bear a higher rate of carriage. (3) It was already carried in much larger quantities, and the traffic was likely in the near future to be very much increased, and so the railway companies could well afford to carry it at a cheaper rather than at a dearer rate.

As the result of these representations the railway companies have admitted the justice of our contention, and have modified the classification in the way we desired. We have thus been completely successful in attaining our object. We may mention, to prevent misunderstanding, that although in January last we were officially informed that we must pay the higher rates for the carriage of petrol, viz., the fifth class rates, we have never charged our customers more than the third class rates on any petrol sent to them by the six principal railways running out of London.

As a last word, we think our best thanks are due to the railway companies for having finally taken our whole case into fair consideration and, when they know all the facts, for having decided it on its merits by amending their classification in a satisfactory manner.

We feel that in securing a reasonable rate for the carriage of petrol a step in the right direction has been made, and we thought the account of the negotiations might not be without some interest.—Yours faithfully,

(For Carless, Capel, and Leonard) Wm. J. Leonard.

Hope Chemical Works,
Hackney Wick, London, N.E.,
June 4th, 1898.

THE STORAGE OF PETROL.

To the Editor of The Automotor.

Sir,—Can you oblige me with a statement of the exact outside limit of petrol I may legally keep at my residence? It may perhaps surprise you to learn that two leading insurance offices, under each of which I hold policies, cannot be persuaded to indicate the limit for which I ask you.—I am, Sir, yours, &c., F. M. Gowan.

26, Clarendon Square, Leamington.

[The law on the subject will be found on p. 60 of The Automotor Pocket-Book. We transcribe that part which contains the information you require:—"Petroleum shall not be kept, used, or conveyed, except in tanks or cases of metal, so made and closed that no leakage, whether of liquid or vapour, can take place therefrom, and so substantially constructed as not to be liable, except under circumstances of gross negligence or extraordinary accident, to be broken or become defective or insecure in course of conveyance or use; and every air inlet in any such tank or case shall be at all times, except when the valve, if any, is required to be removed for immediate use or repair, protected by securely affixed wire gauze, the openings in which shall not be less in number than 400 to the square inch. Every such tank or case shall be clearly stamped or securely labelled with a legible metallic or enamelled label with the words, 'Mineral spirit; highly inflammable; for use with light locomotives.' The amount of petroleum to be in any one such tank or case at one time shall not exceed 20 gallons. There shall not be at the same time on or in any one light locomotive more than two of such tanks as aforesaid. Before repairs are done to any such tank or case, that tank or case shall, as far as practicable, be cleaned by the removal of all petroleum and of all dangerous vapours derived from the same." No, we are not surprised. Insurance companies move too slowly. Our British offices will commence the insurance of oil-motor plants in perhaps 10 years' time—not less. You should communicate with Messrs. Carless, Capel, and Leonard, of Hope Chemical Works, Hackney, London, E. They will advise you on such points.—Ed.]

AUTOMOBILE CLUB DE BELGIQUE—CONCOURS DE SPA, 1898.

À Monsieur le Rédacteur de l'Automotor.

Monsieur,—L'Automobile Club de Belgique a l'honneur d'attirer votre attention sur les Concours d'Automobiles qu'il organise cette année à Spa du 26 au 30 juin et le 3 juillet, concours dotés de prix nombreux et importants.

Des concours débuteront par une course Bruxelles-Spa, 25 et 26 juin en deux étapes, à laquelle seront affectés plus de dix mille francs de prix.

La course Bruxelles-Spa est destinée surtout à être une course d'amateurs; c'est pour cela que seuls sont autorisés à s'inscrire les personnes propriétaires de la voiture engagée ou les membres des Sociétés automobiles reconnues. Les concurrents pourront se faire accompagner d'ouvriers mécaniciens, mais non leur confier la conduite de la voiture. Ces mesures ont été prises dans le but de permettre aux simples particuliers propriétaires de véhicules automobiles de concourir avec quelque chance de succès.

La course Bruxelles-Spa sera suivie d'autres concours, tous dotés de prix nombreux et importants, dont vous trouverez le programme ci-contre.

La Compagnie du Nord-Français accorde à l'Automobile Club de Belgique une réduction de 50 p. c. pour le transport sur ses lignes de toutes les voitures prenant part au concours et expédiées de Paris.

Veuillez agréer, Monsieur, l'expression de notre considération distinguée.

Comte F. van der Stratem-Ponthoz, *Le Président.*
G. de Savoye, *Le Vice-Président.*
Comte F. de Villegas de Saint-Pierre,
Le Secrétaire-Général.

HUNTER'S MOTOR AND AERONAUTICS.

To the Editor of The Automotor.

Sir,—It may interest many of your readers to learn that the navigable balloon, in the car of which M. Gaudron made his first ascent from the Alexandra Palace on Whit-Monday, was fitted with a "Hunter" motor of the type recently described in your pages, having two 3-inch cylinders, and furnished with a suitable gear for driving the propellor.

This is specially worthy of note as being the first balloon ascent in England in which the motive power has been derived from a mechanical source, manual power alone having been employed in previous attempts. The weather was unfortunately wet and squally, but enough was achieved to demonstrate the suitability of the motor and the practicability of the system. When the car was being fitted at our works we had it suspended and tried, and the non-vibrating qualities of the "Hunter" motor were again proved, the occupant of the car declaring that the vibration was practically inappreciable.

As this motor was specially designed, and is intended mainly for autocar work, we are perhaps not trespassing too far in asking you to be good enough to give publicity to those items in your next issue.—We are, yours faithfully, Hunter and Co.

Eastdown Works, Lewisham, *June 1st*, 1898.

The German Motor-Vehicle Competition.—We notice some good features in the regulations which governed the German competition of motors which was held at Berlin from May 24th till the 27th. The meeting was divided into three parts, the first being the exhibition of vehicles; second, the race to Potsdam; and the third the distance run to Leipsic and back. It appeals to our mind that this is the right course to take, since the judge can easier define the good points of each make and compare with others when the criticism is restricted to a special capacity, quickness, finish, or durability. He is then not overwhelmed by a concurrence of numerous commendable and objectionable points. The subscription money was divided into two parts bearing the proportion of 40 and 60 per cent. The 40 per cent. were distributed amongst all the drivers who made the run within a certain time, whilst the 60 per cent. only were devoted as prizes. The stake for the show was £1 for the first vehicle entered by one maker, and 10*s*. for every additional one. For the race the same rate prevailed, but for the run to Leipsic £3 and 30*s*. were fixed. All these payments were trebled after May 14th, 10 days before the meeting.

LAW REPORTS.

Beeston Pneumatic Tyre Company.

An appeal by defendants in the case of Stroud *v.* Lawson and others on the 16th ult., came again before the Court of Appeal, consisting of Lord Justices A. L. Smith, Chitty, and Vaughan Williams. Plaintiff in the action, Mr. Frederick Stroud, sued the defendants, Lawson, Bradshaw, and Felley, directors of the Beeston Pneumatic Tyre Company (Limited), the Company being joined as a fourth defendant, first, on his own behalf to recover £500 damages, alleging that the defendant directors, by fraudulent conspiracy, raised the price of shares on the market, so inducing him, as one of the public, to buy shares at enhanced prices; and, secondly, claiming, on behalf of himself and all other shareholders, that a dividend of £30,000 paid by the directors was not paid out of profits of the Company, but was obtained from the British Motor Syndicate, of which the defendant Lawson was chairman, for which sum of £30,000 the defendants wrongfully issued to the British Motor Syndicate 15,000 fully-paid £2 ordinary shares, and that such payment of dividend being *ultra vires* and illegal, the defendants should account for it to the Company. Defendants applied to Mr. Justice Darling that plaintiff's statement of claim should be struck out as embarrassing, unless he elected to amend it by choosing between the two causes of action set up. Mr. Justice Darling refused to make an order, and from this refusal the defendants now appealed. Lord Justice Smith, in delivering judgment, said he held the opinion, contrary to that held by Mr. Justice Darling and the Master, that the plaintiff should be put to his election as regards the two causes of action which appeared in his statement of claim. Plaintiff sought to join a well-known common law action and what used to be a well-known action in the Chancery Division into one. They were based on separate causes of action, not arising out of the same transaction. In the first action the whole substance was fraudulent conspiracy alleged on the part of the directors; in the second action, respecting the payment of a dividend alleged to be *ultra vires*, the plaintiff had not got to prove fraud of any sort or form. In these actions were different plaintiffs, different causes of action, different matters of law raised, and different defendants, and he was therefore of opinion that this appeal should be allowed and Mr. Justice Darling's order varied. Lord Justice Chitty and Lord Justice Vaughan Williams concurred, and the appeal was allowed, with costs, the plaintiff being allowed 21 days within which to make his election.

The Great Horseless Carriage Company.

In the Court of Appeal, on the 13th inst., before Lords Justices A. L. Smith, Rigby, and Vaughan Williams, the case of the Great Horseless Carriage Company (Limited) *v.* Haigh came up on defendant's appeal from an order by Mr. Justice Darling on May 17th, giving leave to the plaintiff Company to sign final judgment under Order 14 for a sum of £425 due for calls on shares. Mr. Disturnell appeared for the appellant Haigh, and Mr. Longstaffe for the liquidator of the plaintiff Company. Mr. Disturnell, in support of the appeal, said the defence raised by Mr. Haigh in his affidavits was that he was induced to take those shares in the Great Horseless Carriage Company by fraudulent misrepresentation on the part of the directors. Had that been the whole case, counsel apprehended there would have been no liberty to defend; but in January last a resolution was passed for the voluntary winding up of the Company, and it was now said that after the Company had gone into liquidation this defendant, even under the circumstances which he had described, could not set aside the allotment made to him. But here the circumstances were altogether exceptional. So far as creditors were concerned, there were no creditors of the Company, and no assets which could be utilised for the adjustment of the rights of contributories amongst themselves, because the whole of the assets would be divided, one part going to a new Company which would allot shares to shareholders of the Great Horseless Carriage Company on a further payment, and another part going to the promoters of the Company—the people who were mainly responsible for this alleged fraud upon the public. Voluntary liquidation commenced in January last, and this action on April 27th. The reason why steps were not taken earlier to set aside the allotment was that defendant did not appreciate fully the circumstances under which the Company was floated until a large number of actions were commenced against this Company, claiming damages for fraud and leave to set aside allotments. It was decided that one of these actions should be selected and treated as a test action, and Mr. Haigh waited for the result of this test action to be known. It was down for trial in the Queen's Bench Division on July 5th next, and, there was every reason to believe, would be reached before the long vacation. Nobody expected a liquidation, because it was known that the Company was not trading and was not incurring debts. It was alleged that the whole of this liquidation was collusive, for the purpose of preventing any inquiry into the circumstances under which this Company was promoted. Mr. Longstaffe, for the respondents, supported the order appealed from, arguing that after winding-up commenced the shareholder could not escape, even had this matter been the absolute fraud that was alleged. After the resolution in January for winding-up, the appellant received notice that a list of contributories would be settled on March 16th by the liquidator. He made no objection to that, and it was not until the writ in this action was served and application to sign final judgment made that he set up this story that he had been defrauded. Lord Justice Vaughan Williams: Is it your contention that under no circumstances can a voluntary liquidation ever be got rid of and undone? Mr. Longstaffe did not suggest that, but argued that the appellant, not having taken any steps when he received notice from the liquidator that on March 16th a list of contributories would be made up, was not now entitled to be relieved from his liability. Their Lordships allowed the appeal, with costs, Lord Justice Smith remarking that when these transactions came to be tried it might be proved to be most unjust to sign final judgment against this gentleman without hearing his case, under an order of the Court by which he could be made a bankrupt.

New Motive Power Syndicate.

On June 9th and 10th Mr. Justice Bingham and a common jury had before them the case of Canning and another *v.* the New Motive Power Syndicate (Limited), the claim being for £78 16*s.*, balance of account for a report on Guattari's patent mixture for boilers. Defendants counterclaimed for damages alleged to have been done to the boilers. Mr. McCall, Q.C., Mr. Macaskie, and Mr. Howard Speucely appeared for the plaintiffs; and Mr. Tindal Atkinson, Q.C., and Mr. A. B. Shaw were for the defendants.

It was alleged by the plaintiffs, Sir Samuel Canning and Mr. T. E. Gatehouse, that the defendants, who were interested in Guattari's patent, which was a mixture of carbonic acid gas and a preparation of chloride, arranged that they should test and report upon it for a fee of 150 guineas, and half that sum was paid down, while the balance was to be handed over at the conclusion of the contract. It was held that the mixture, if put into a boiler, would increase the motive power. Steam would be more quickly generated, and there would be a considerable saving of fuel and water. Two tests took place in certain boilers with the patent mixture, and with plain water, and the result was that plaintiffs came to the conclusion that no better results were obtained from the mixture than from plain water. When that was discovered, it was alleged that Mr. Bale, one of the directors of the defendant Syndicate, objected to the way in which the tests were made, and also objected to receive the report and pay the balance of plaintiffs' fees.

Several witnesses on behalf of plaintiffs gave technical evidence as to the manner in which the tests were carried out, and tabulated statements were handed into Court showing the results.

On behalf of the defendants, Mr. Tindal Atkinson stated that the secret mixture of Guattari's was said to make the water in a boiler extremely volatile, so that it gave off steam with a much less consumption of fuel than ordinary water would require. Upon certain reports as to the utility of the patent, a Syndicate had been formed of which the defendants were members, and they subscribed some £1,500 for the purposes of carrying into effect and rendering a popular success, if possible, the invention of Mr. Guattari. Then arrangements were made with plaintiffs to test the boilers. The tests, however, made on two separate days in August last were not performed under the same atmospheric conditions, and it was alleged by defendants that they were unfair tests, and were not sufficiently prolonged, and that damage was done to the boilers through the way the tests were managed. Hence the refusal to pay the balance of account which formed the subject of the action.

Several witnesses were heard for the defence, one of whom admitted that Mr. Guattari was now on the Continent, and had declined to come over to assist the Syndicate. Another witness, Mr. John Humes, the consulting engineer to defendants, said the test was not a fair one. In answer to his Lordship, witness said that the Syndicate, which had taken over Gnattari's process, had not yet sold it, and he could not say whether it was worth anything or not.

In replying upon the case, Mr. McCall said that what the Syndicate wanted was a good report, which would have enabled them to pass off to the public the invention they had purchased from Guattari. Finding that Mr. Gatehouse and Sir Samuel Canning could not conscientiously give the Syndicate the glowing report they desired, objections were raised, and hence the appearance of the parties in Court.

His Lordship, in summing-up, said the real question the jury had to decide was whether plaintiffs did their work in a proper and conscientious manner. If a skilled person were employed to do a certain thing, he must do it with the skill which a person in his business would be expected to use. Defendants complained that plaintiffs had not exercised their skill upon the experiments in question. Now, the defendants bought Guattari's patent, and a kind of first Syndicate was formed, which raised a sum of money with the object of testing the process to see whether it was really worth anything. An experiment was made—which was not the subject of this action—with the result that Syndicate No. 2 was formed, which seemed to think that the proper thing to do was to sell the patent to the public. Before, however, it was put before the public it was thought best to get from a good firm, with a good name, a favourable report, which would in due course be printed in the prospectus. What the Syndicate wanted was a report which was favourable, for any other would have had no commercial value for them. The main point, however, was—Did the plaintiffs bring to bear, when making the tests, that skill, care, and judgment which competent men in their position ought to bring? If they did, they were entitled to balance sued for, and if not they would have to refund the sum had already been paid them.

jury at once gave a verdict for plaintiffs for the amount

Bankruptcy Court.

AT the Bankruptcy Court, on May 18th, the first meeting of creditors was held in the case of C. E. Monkhouse, described as a company promoter, of 38–39, Parliament Street, Westminster. It appears that the debtor during the last two years has been engaged in company promoting, and was interested in the Peerless Metal Company (Limited), and the Letay Motor-Engine Company. The liabilities were returned at £821, with assets nil. The debtor ascribes his insolvency to the action taken by the petitioning creditor in respect of a bill accepted on behalf of Mr. W. B. Norris, and to law costs incurred in connection therewith. He has also lost £200 or £300 by horse-racing. No offer was submitted, and the case went into bankruptcy with the Official Receiver as trustee.

IN the Chancery Division on the 11th inst., before Mr. Justice Stirling, Mr. Sarjeant applied for the appointment of a receiver in the matter of R. F. Hall and Co., cycle manufacturers, &c. Counsel stated that the Company had got into difficulties, and an action had been brought against them by Lloyd's Bank. There was £50,000 worth of material in the business, but it was in an unmerchantable state, and £4,000 would be required to make it marketable; £400 was also required to pay wages due to the workmen that day. The present application was made on behalf of debenture holders. His lordship consented to the appointment of a named gentleman as receiver, and gave leave to borrow £400.

Furious Driving.

AT Brighton, on the 30th ult., Harry Parton, of 94, Fernhead Road, Paddington, London, was summoned for driving a light locomotive on the King's Road, on May 22nd, at a speed greater than was reasonable and proper, having regard to the traffic on the highway. Defendant pleaded guilty. P.C. Fellingham said that he was on duty on the King's Road, close to Regency Square, on Sunday evening, May 22nd, when he saw the defendant driving a motor-car at a very rapid speed on the wrong side of the road. When opposite the Metropole defendant, through his reckless driving, caused a horse to take fright and run into a cab standing on the cab rank. The defendant did not stop to see what mischief had been done, but witness saw him on the following day, when he gave his name and address. Defendant stated then that at the time his motor-car was geared up to a speed of about 12 miles an hour, but, being on level ground, it would have increased to about 14 miles. A cabman said that what with the steam and the rate the defendant was coming, his cab was thrown back on the rank. His cab was not actually touched by the defendant's vehicle. Defendant said he pleaded guilty to furious driving. Mr. Carter stated that he believed defendant was an experienced man. There were two ladies in the motor-car at the time. Defendant was engaged by a gentleman for the express purpose of driving the car. The stipendiary, in fining the defendant 40*s.* and costs, or a month's imprisonment, pointed out that although 12 miles an hour was the maximum at which these light locomotives could be driven, the speed must depend on the state of the traffic, or on other circumstances.

MORE FURIOUS DRIVING.—At the Petty Sessions, Bromsgrove, on June 7th, Charles Sangster, Selly Oak, was charged with driving a motor-cycle on the Birmingham New Road, near Marlbrook, at a furious rate. Mr. Gerald Botteley, solicitor, Birmingham, defended. Police constable Price stated that defendant was driving at a "furious rate"—he thought 25 or 30 miles an hour. It was a dangerous rate. Another witness stated that he saw the motor-cycle going very fast—he thought 30 miles an hour. He was informed that the cycle was geared to 12 miles an hour, and he then said it might not have been more than that. After further evidence of an exceedingly loose nature, Mr. Botteley quoted from the Locomotives on Highways Act to the effect that no light vehicle should travel at a greater speed than 14 miles an hour; and evidence was given that the machine was geared to 12 miles an hour, and the brakes were effective. Defendant was fined £3 10*s.*, including costs.

AT the West Riding Police Court, Leeds, on the same day, Rowland Winn, a cycle engineer, of Leeds, was fined 5*s.* and costs, for riding a motor tricycle at a furious rate on the high road at Adel. A police constable estimated the speed which the machine attained when he saw it at from 17 to 20 miles an hour.

MR. PENNINGTON AND FURIOUS DRIVING.—On June 3rd, at Shifnal Police Court, Mr. Edward John Pennington (Wolverhampton), inventor, was charged with four breaches of the Light Locomotives and Highways Order, 1896, in the parishes of Shifnal, Albrighton, and Boninghal, on April 23rd. The allegations were that he was driving a motor-carriage at a dangerous speed, and that he did not pull up stationary when signalled by the driver of a vehicle. He was fined £18 15*s.* 8*d.*

At the Wolverhampton Sessions Court, on the 6th inst., the same person was summoned for driving a motor-car at a furious rate along the Wergs Road, Tettenhall, on May 9th. Defendant did not appear, and was represented by Mr. Wright, from the office of Messrs. Fowler and Langley. Superintendent Price informed the Bench that there had been a number of complaints made as to the danger resulting from the way in which the defendant drove his motor-car, and he had been summoned at Shifnal for a like offence. It had been found necessary to take proceedings, or people might be injured. Thomas Smith spoke to seeing the motor-car travelling at a speed of about 30 miles an hour; and Edward Denning, who saw the car, estimated the speed at 25 miles an hour. Witness was riding on a cycle, and tried to keep pace with it, but although he rode a mile in two and a half minutes he lost sight of defendant and his car. Another witness thought the speed was about 20 miles an hour. A plea of guilty was put in, and the Bench imposed a fine of £2 10*s.* and the costs.

Vehicles in China.—In the course of an interesting article in *Engineering*, descriptive of the industrial development that is taking place in that country, the writer says:—"The Chinese wheeled traffic is worthy of notice. Their principle of selection has resulted in the evolution of two forms of vehicle in North China, the wheelbarrow with a large narrow single central wheel, with seats on each side of the wheel on which six to eight persons, or an equivalent freight, are carried by the individual coolie, and the one-axled cart with wheels of small diameter and iron-studded tyres about $1\frac{1}{2}$ inches wide. These carts are very solidly framed, and often carry loads of several tons, drawn by a composite team of one or two bullocks, one or two donkeys, and one or two mules or Tartar ponies; generally four or five draught animals in each instance, connected together by long rope traces."

MOTOR-VEHICLE TRIALS AT BIRMINGHAM.

(BY OUR OWN CORRESPONDENT.)

The second of the annual trials of heavy automotors held in connection with the Royal Agricultural Society's Show were commenced on Monday, the 13th inst. This year the trials were held in the same neighbourhood as the Show, viz., Four Oaks Park, Sutton Coldfield, near Birmingham. Apart from the advantages of the park and the charms of the picturesque and well-wooded town-village of Sutton Coldfield, the district, though hilly, is well suited for trials of heavy motor-vehicles. I had occasion about a fortnight ago to drive all round Sutton Coldfield, Aldridge, Little Aston, and Streetly, and was much struck by the excellent condition of the roads, not merely in the immediate neighbourhood of Sutton Coldfield itself but of the district generally. As compared with the roads at Crewe last year, the vehicles had an easy time of it, and in forming my opinion on the respective merits of the competing vehicles for the transport of produce, &c., I have not forgotten to contrast these excellent roads with those near large industrial centres like Manchester and Liverpool, the roads outside the latter town being simply execrable.

It was understood that the vehicles were to be on the ground on Saturday, but when I arrived I was an easy first. By prosecuting inquiries I learned that most of the vehicles were putting up independently. A Daimler wagonette was running in Sutton and attracted a great amount of attention, but otherwise everybody, official or otherwise, seemed profoundly ignorant concerning the trials. This was rather a surprise to me, seeing that Sutton is comparatively near to that important centre of the motor-car industry—Coventry.

Fig. 2.—Messrs. Roots and Venables' Heavy Oil (High Flash) Van.

The trials attracted much more attention this year from the trade, however, the entries being far more numerous, and, what is still more important, the number of vehicles that put in an appearance was encouraging, after the grand total of unity attained last year.

Entries.

There were two classes under which vehicles might be entered, viz.:—

Fig. 1.—Daimler Petrol Van.

Class I—for vehicles carrying (not drawing) 1 ton—under which the Daimler Motor Company had a very neat and business-like van (Fig. 1). It was
4 H.P. Daimler
framing is that usua
the Company, only
speeds, rising from
hour as a *minimum*
as a *maximum*, th
speeds being four
respectively. The l
with a removable canvas covering and a tilt back. The trunk of the van, so to speak, is narrower than the head and end, being 3 feet 4½ inches wide, the ending being 4 feet 1 inch wide. The total length from the back of the front seat to the tail-board is 4 feet 10 inches. The brakes provided are three in number and powerful—a good feature—and include the usual foot-brake acting on the counter-shaft; a brake on each of the sprocket-wheels, attached to the driving-wheels, which is operated by hand; and separate screw-brakes on the two driving-wheels. In addition to these there is the familiar sprag. Seven gallons of petrol were carried, sufficient to carry the van 70 miles.

The greater part of Monday morning was spent in weighing the vehicles, &c. The first to leave was the Daimler van, which, under the skilful guidance of Mr. O. Mayer, was put round the prescribed route of over 13 miles in less than 1½ hours. The consumption of fuel was five pints of petrol. The load carried was 2,200 lbs. sand and two passengers (including driver). Total weight, 2 tons 8 cwt.

(including vehicle, load, water, oil, &c.). A lorry was entered in this class by Mr. H. P. Saunderson, of Bedford. It was driven by a petrol motor with one cylinder, and of the horizontal type. The lorry was a wooden body on a steel frame. Unfortunately, it had a breakdown in the mechanism, due to defective packing.

In Class II, for vehicles to carry 3 tons, Messrs. Roots and Venables had a van (Fig. 2) which has been built to the order of Messrs. Peek, Frean, and Co. The van is driven by a twin-cylinder Roots' oil motor, of 6 H.P., and is intended to carry a load of 1 ton. Ordinary petroleum oil, such as "Tea Rose," is used, as is the case with all the vehicles made by this firm; in fact, we believe they are the only makers of cars and other vehicles whose motors are driven by this safe fuel. Petrol and benzoline cannot be handled with the same impunity. The crank-shaft of the motor, which runs at about 500 to 520 revs. per minute, is, in the case of the slow speed, geared by means of mortice wheels and friction clutches with a counter-shaft, on the ends of which are chain wheels connecting it to the driving wheels. The quick speed is obtained by connecting the crank-shaft to the counter-shaft direct without the intervention of the mortice wheels. The balance gear is fixed at one end of the counter-shaft. The friction clutches are used for graduating the speed as desired between the maximum and about one mile an hour. There is a third friction clutch which can be put into gear for reversing. The steering is on the Ackerman principle—operated directly by a hand lever. Two brakes—one a band brake on the counter-shaft, and the other an ordinary foot brake acting on the iron tyres of the driving wheels—are under easy control of the driver. The van is painted in the well-known colours of Messrs. Peek, Frean, and Co., the upper part of the body being a rich cream, while the lower part and wheels are green.

In this class there were also two lorries, one by the Steam Carriage and Wagon Company (Thornycroft's), of Chiswick (for illustration *see* p. 330, Fig. 9), and the other by the Leyland Steam Motor Company (*see* p. 331, Fig. 10). The former took a full load and did the course in 2 h. 29 m. Full particulars of this vehicle and the Leyland will be found in the Liverpool Trials article.

The Leyland lorry did the course in 2 h. 31 m., though it was running under difficulties owing to a temporary hitch with the air-pump that maintained the pressure for the oil-burner. It did the journey down to the Show ground—a run of 110 miles—in a day and a quarter without a hitch. They were burning Russian oil, though the lighter American product is generally used. Owing to the late start the amounts of coal or oil consumed were not officially announced on Monday, and the award list will not be issued until the Monday of the Show week.

A steam buckwagon by Jesse Ellis and Co., of Maidstone, was also entered, but had unfortunately not been able to get to the ground in time. This wagon (Fig. 3) has been built for service in South Africa, Australia, &c. The body is stoutly constructed of wood bolted to a steel frame, and has a carrying capacity of 6 tons exclusive of the weight of the wagon. At the front end of the wagon is arranged the cab containing the machinery, which is placed above the floor to enable rivers to be forded without wetting the engine, boiler, &c. All the operating levers are brought together in the cab and arranged so as to be under the control of one man. The engine has been specially designed, and is a compound vertical engine with one distributing piston-valve to both cylinders and a single eccentric reversing gear. The engine will be found to possess many features of interest, especially when it is remembered that its weight is so little. The boiler, which is of ample size to supply steam to the engine, is an improved type of vertical tube boiler with exceptionally large heating surface and is designed to burn either solid or liquid fuel. The condenser is placed in the roof of the cab and is a patent atmospheric condenser provided with a fan driven from engine. Special attention has been paid to the gearing, which consists entirely of spur wheels, a chain being found unsuitable for such a heavy drive. A two-speed gear and differential motion are provided. The steering is effected by revolving a hand-wheel which actuates by means of a worm and worm-wheel two drums with chains attached, one to each side of fore-carriage. The steering wheels are attached to the fore-carriage which is provided with a ball race and phosphor-bronze balls. A hand-brake suitable for ordinary working and a powerful emergency steam brake are arranged in suitable positions. The wagon is also provided with a hauling drum and a long length of steel wire rope for use when fording rivers. Clutches are arranged for throwing the driving wheels or hauling drum in and out of gear as required. The oil and water tanks are fixed under the wagon and are of a large capacity for a long run. The maximum speed on level is 10 miles per hour.

FIG. 3.—JESSE ELLIS AND CO.'S STEAM BUCKWAGON.

The judges were Messrs. Bryan Donkin, Webb, and Prof. Unwin, accompanied by Mr. Courtnay, the engineer to the Society. The unavoidable, and in some cases wholly unexpected, delays made it very difficult to obtain anything like reliable details during the progress of the trials, but we shall be able to supplement this brief account of the trials by a more detailed description in our next issue.

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "The Automotor and Horseless Vehicle Journal" by Herbert Haddan and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

Specifications Published.

The following is a List of Specifications recently published, and obtainable at the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform charge of 8*d*. per copy. Owing to the enormous pressure upon our columns it has been found impossible to deal in any other form with the accumulation of patents now being taken out in connection with automobilism. As far as possible, a selection for special mention is made by the Editor from the more prominent inventions:—

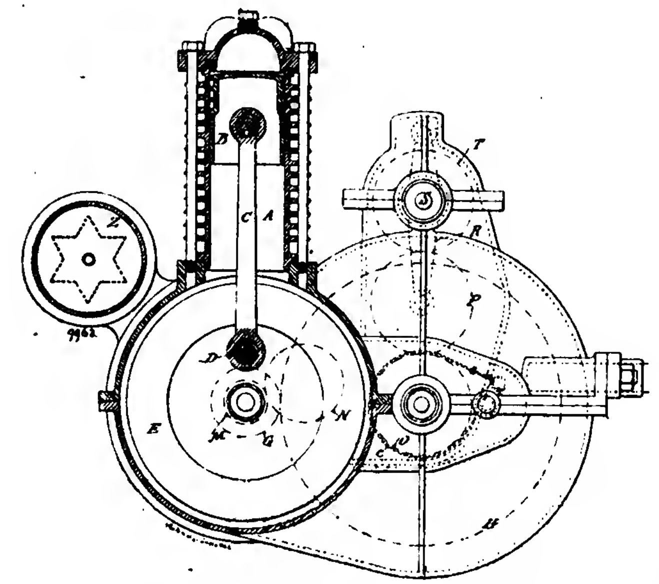
9,963. Carburetted Air or Internal Combustion Engines. A. H. L. Grivel, 6, Rue des Poissonniers, Neuilly (Seine), France. April 21st, 1897.

The piston of each of the two cylinders is coupled by means of a connecting rod to a crank, each of these cranks having a double fly wheel. The two cranks are set at an angle of 180° to each other in order to obtain one explosion at each rotation of the driving shaft.

The driving shaft carries a pinion gearing with a wheel which drives the motor-axle of the vehicle through the intermediation of a differential gear constituted by four conical pinions suitably disposed in relation to one another in a box or casing. The connection of this wheel with the differential gear is effected by the intermediation of a slightly conical ring interposed between the differential gear and the nave of the wheel; there is thus obtained a secure driving contact of these parts.

The exterior of the differential gear box is formed or turned so as to constitute the drum of the brake, and a spring-band or strap is suitably mounted so as to bear upon the drum thus formed and stop the movement of the vehicle when the driver operates the brake lever.

The operation of the escape valves is effected by cams suitably mounted upon spindles and set in motion by the driving shaft through the intermediation of gear wheels.



Upon the differential gear box is mounted a pinion which gears with a second pinion carried by an arm adapted to pivot around the spindle of a third pinion. By turning this third pinion the wheel which drives the motor-axle of the vehicle as before described is set in motion (the cone ring before described having been first put out of gear to prevent starting of the vehicle), and this wheel, gearing with the pinion on the driving shaft of the engine, starts the motor. As soon as the engine is started, the spindle of the third or starting pinion is released; the first pinion then repels the second pinion which is displaced and automatically throws the apparatus out of gear.

The invention also comprises improved means for varying the speed of the engine by producing longer or shorter intervals of time between the successive explosions in the cylinders of the engine. An insulating cylinder is provided which rotates on its spindle and carries a metallic piece upon which a spring contact constantly presses. Two other spring contacts are provided connected respectively to the poles of the induction coil which produces the igniting spark.

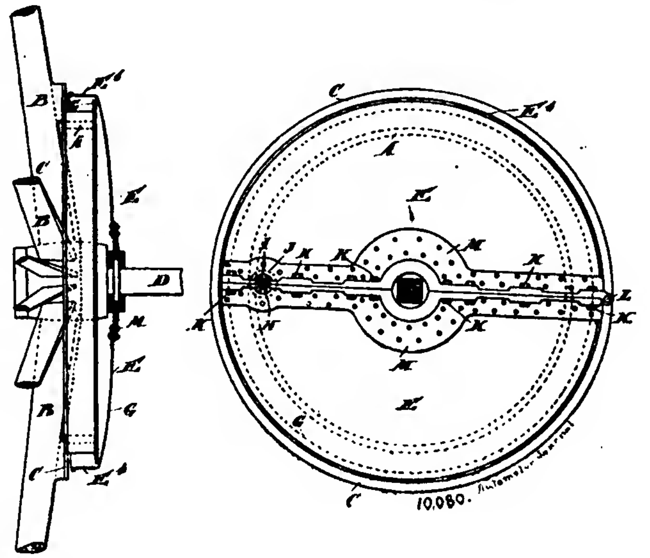
The box which carries the two last-named contacts is capable of being moved slightly on its axis by means of a suitable handle worked by the driver, its movement being guided and limited by suitable slots. According to the position of the box the spring contacts connected to the induction coil will come in contact a little sooner or a little later with the metallic piece on the insulating drum, and will thus vary the time between the successive explosions of the charge and thus modify the speed of the engine.

The carburetter is preferably placed at the back of the motor, and is rotated by means of a small belt from any suitable shaft; the carburetted air or mixture of air and vapour is led by a pipe to the chamber from which the suction valves draw the charge into the cylinders.

10,080. Driving Gear for Motor-Carriages. R. R. Symon, 20, Abchurch Lane, London, and H. A. House, Junior, East Cowes, Isle of Wight. April 22nd, 1897.

Relates to driving gear for motor-carriages, and has for its object the provision of means for preventing the entrance of dirt into the teeth of the gear.

The gearing is of the kind known as internal tooth gearing, and the internally geared wheel, A, is mounted on the inside of the spokes, B, the side of the internally geared wheel that comes next to the road wheel being closed with a disc or plate of sheet-iron or other suitable material, C, fixed to the road wheel or to the geared wheel, or, if preferred, cast with the latter, so that no dirt can enter the teeth from that side. On the stationary axle, D, of the carriage is fixed a disc or plate of sheet-iron or other suitable material, E, the periphery of which is turned up or otherwise flanged all round as



shown at E[1], thereby forming a kind of circular dish, into which the aforesaid internally geared wheel enters, so that the inside face of the latter is covered by the bottom of the dish, and its outer periphery by the turned up or flanged edge, E[1], thereof. The internally geared wheel, A, is thus enclosed at its two sides between two discs, one of which, C, rotates with it, and the other, E, remains stationary, and peripherally by the turned up or flanged edge, E[1], of the stationary disc, E; and if it were possible to preserve a close joint between the rotating and stationary parts, no dirt or dust could get into the gearing; but as that is not practically possible, a radially projecting flange, G, is formed on the inner edge of the outer periphery of the internally geared wheel, A, which flange prevents any dirt that enters between the rotating and stationary parts getting into the teeth of the gearing, and guides it round to the lower part of the flange, E[1], of the stationary dish, where a hole or holes may be provided for its escape.

The stationary disc or dish, E, E[1], is provided with an opening, H, through which the shaft, I, passes, carrying the pinion, J, that gears with the teeth of the internal wheel, A; and, if desired, this opening may be made large enough to enable the pinion itself to be passed through, the opening being, however, covered with a suitable cover-plate after the pinion is in place. The enclosing discs and other parts may be made in two or more pieces connected together by rivets or by bolts and nuts, K, or hinged as at L.

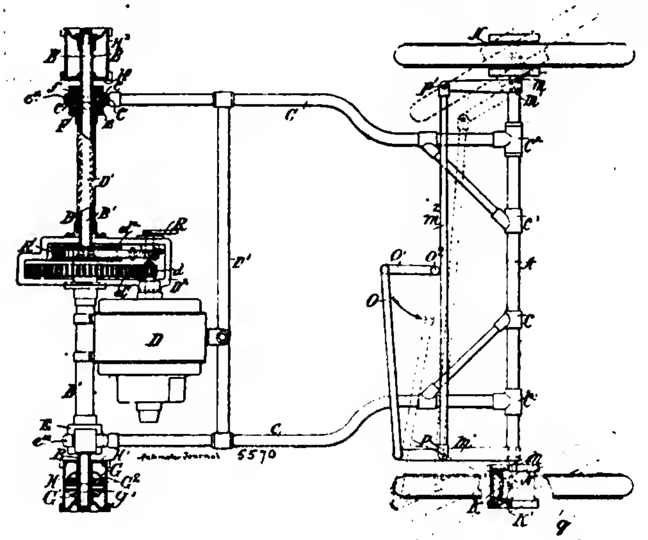
A modified form is also described.

5,570. Motor Road Vehicles. J. Y. Johnson; communicated by A. L. Riker, New York, U.S.A. March 7th, 1898.

This invention relates to the construction of motor or self-propelled vehicles, and more particularly to the running gear thereof, and consists of an approximately rectangular running gear frame in which the two axles are capable of independent vertical play while being retained in substantially parallel vertical planes by means of side-bars, the said bars being each attached to the rear axle by a universal joint, and one of the bars being secured rigidly to the front axle, while the other is secured thereto by a swivelling connection.

The rotating axle has a collar near each end, and a relatively stationary casing surrounding the axle having an enlargement at each end, ball bearings being situated within the enlargements and against the outer side of the collars, means being provided for tightening the balls up against the collars. The relatively stationary casing has a spherical seating near each end.

The driving-shaft comprises two axles located one within the other, a hub at one end of the said axles enclosing a compensating gearing, the said gearing comprising a bevel wheel secured on the inner axle, a bevel wheel on the hub, and bevel pinions, mounted to



rotate upon a support rigidly connected to the outer axle, and arranged between and gearing with the bevel wheels.

A brake drum is provided fast on the driving-shaft, the brake-lever being mounted on the casing that surrounds the driving-shaft and driving-gear, and the brake-band passed around the drum and secured to the lever.

The hubs have race-ways for ball bearings near each end, and annular ball-retainers, in combination with a cylindrical box, mounted upon the end of the axle by a vertical pivot, and an arm for turning the box, and with it the hub.

A bolt passes through the axle and the box, pivoting the latter upon the former, the said bolt having a conical shoulder near its upper end, and two sets of ball bearings, one between the said shoulder and the upper face of the axle, and the other between the lower face of the axle and the cylindrical box.

24,881. Explosion Engines. J. B. Furneaux, Victoria Works, Gateshead-on-Tyne, Durham, and E. Butler, Coatesworth Road, Gateshead-on-Tyne. November 6th, 1896.

In this engine there are two cylinders, each open at one end, arranged side by side and provided with trunk pistons connected to a pair of oppositely arranged cranks on a common shaft provided with one or more flywheels. Situated midway between the two cylinders and at or near the combustion end thereof is a casing provided with a balanced circular distributing valve and with two pairs of oppositely arranged ports that communicate with the combustion chambers of the two cylinders by suitably arranged pipes or passages. This casing with ports and connecting passages may form one casting with the two combustion chambers. The valve is arranged to be rotated once for each six revolutions of the crank-shaft by a worm fixed on the crank-shaft between the two cranks and gearing with a worm wheel fast on a shaft connected to the valve. The arrangement is such that there is an explosion or working outstroke at every third revolution of the crank-shaft, the two cranks being arranged at an angle of 180° apart.

The balanced valve is constructed with three pairs of oppositely arranged channels or portways, the first pair communicating with the supply pipe or passage for explosive mixture, the second pair communicating with the exhaust pipe and silencer, and the third pair communicating direct with the external atmosphere, it may be through one end of the valve, and serving to supply and exhaust a cooling charge of air on the fifth and sixth strokes of the cycle of working. Each cooling charge of air also has for effect to clear the combustion chamber, cylinder, and ports of all residual gases from the previous explosion.

During the rotation of the valve the series of channel or portways contained in the valve are brought into communication with the ports communicating with each cylinder alternately; the cycle of working of one cylinder being one and a half revolutions in advance of the other.

The explosive charges may conveniently be ignited by electric igniters located in the combustion chambers of the cylinders and between which electric sparks can be produced by means of a sparking coil actuated by a dry battery and controlled by a commutator attached to, and receiving motion from, the said valve or valve shaft, the arrangement being such that the charges in the two combustion chambers are ignited in an alternate manner.

The cylinders are or may be provided externally with a series of cooling rings or ribs, arranged preferably at right angles to the axes of the cylinders, for the purpose of presenting a large heat radiating surface and preventing overheating of the cylinders.

14,559. Instantaneous Steam Generators. J. Simpson, Braehead, Whins of Milton, Stirling. June 16th, 1897.

The improved steam generator is of the class in which the water supplied to it is practically flashed into steam upon contact with the heating surfaces, and the latter are composed mainly of inner and outer concentric tubes through the annular spaces between which the water passes and the steam generated flows to a receiver or the engine. The tubes are arranged horizontally or approximately so in staggered rows over a furnace which may be formed by jets of hydrocarbon vapour or by liquid fuel burners, and their ends are connected to vertical end headers or slabs forming the end walls of the combustion chamber and generator, the outer tubes being connected to the inside plates of the end headers, whilst the inner tubes passing through are connected to the outside plates thereof. The ends of the tubes may be expanded or screwed into the respective plates of the end headers or slabs, and they are retained in place by means of screwed lock nuts whose bearing faces are preferably recessed and filled in with copper wire or like packing to form a tight joint. The steam or water spaces within the end headers or slabs are made as shallow as practicable, and these spaces are divided by distance pieces which are arranged to direct the flow of the water and steam in a sinuous course through the tubes and end headers. The water or steam circulating through the annular spaces between the tubes is subjected not only to the heat applied to the surface of the external tubes, but also to heat applied to the surfaces of the inner tubes either by carrying the furnace gases through them, or by directing through them the flame or jets of a separate heating arrangement.

A number of the inner tubes of the lower and upper rows, instead of forming fire tubes, are plugged at one end and extended through the end walls at the opposite end so as to form at the lower end an inlet for the water, and at the upper end an outlet for the steam. These inlet and outlet tubes are perforated to permit of the passage of the water from the inlet pipe to the annular spaces between the tubes, and in the case of the outlet pipes for the passage of the steam from the annular steam spaces to the inner outlet tube. The water entering the feed inlet thus passes through the perforated tubes of the lower row into the surrounding water space, thence into one of the end headers or slabs, back through the annular water spaces of one or more of the rows of tubes above to the opposite end header or slab, and so on back and forth through the tube spaces and headers until the perforated tubes of the uppermost row are reached, whence the steam generated passes to the receiver or direct to the engine. The water supply may be regulated by suitably controlling the feed pump to suit the required consumption of steam.

CONTENTS.

THE PARIS MOTOR-CAB COMPETITION.

In our last issue we gave some of the leading features of this competition, which has been promoted by the French Automobile Club, but as we were going to press just as the trials terminated our account was necessarily meagre. We are now enabled to deal more fully with the matter, but before plunging into the very voluminous data which the officials with an assiduity that cannot be sufficiently commended have collected, and most of which has been placed at our disposal, we must cordially congratulate the Organising Committee of the Automobile Club and their distinguished colleague, M. Forestier, the various constructors of the vehicles, and all concerned, upon the brilliant success of the competition, which has done more to convince the public of the advantages and merits of automobilism for street traffic than any trials that have yet taken place either in France or Great Britain. So successful has been this competition, or rather so successfully have the vehicles come through the very severe trials, that we may say that so far, at any rate, as Paris is concerned the days of the horse-drawn vehicle are numbered.

Referring for the moment to our former report, it was decided that the competition should embrace a period of 12 days, commencing on June 1st and terminating on the 12th. The vehicles were required to traverse Paris and its environs in various directions, and to ascend the steepest gradients, the steepest being 1 in 15. Each vehicle was required to cover a distance of about 36 miles each day. The Judging Committee was required to pay particular regard to the working cost of a journey of about 36 miles as a minimum in a day of 16 hours; also comfort, ease of manipulation, frequency of replenishing the source of motive power, and the facility for repairs were points to which they had to pay special attention. The vehicles were classed as under:—

1st Class.—(*a*) Closed vehicles for two persons.
(*b*) Open vehicles for two persons, but fitted with a hood.
(*c*) Vehicles for two persons, that can be readily made open or closed.
2nd Class.—(*a*) Closed vehicles for four persons, with roof for carrying 66 lbs. of baggage.
(*b*) Open vehicles for four persons, fitted with hood.
3rd Class.—Closed vehicles for six persons, with roof for carrying 66 lbs. of baggage.

Originally 26 vehicles were entered, but only 12 actually competed; of these 11 were electric motor-vehicles, and one was a petro-motor-vehicle.

Among the vehicles entered were two, Nos. 17 and 18, by the Compagnie Générale des Voitures de Paris. These vehicles were sent over by the London Electrical Cab Company, but they did not take part in the competition. This is much to be regretted, as not only did it prevent any reliable comparison being made between the pioneer London electric cabs and the Paris ones, but also leaves us without any exact information as to the performances of the former. Why the London cabs did not compete we can only conjecture. The various petrol-motor makers, with one exception, also withdrew from the competition, as indeed they were justified in doing since it is now generally recognised that oil-motors are not the most suitable for the congested traffic of the London and Paris streets.

The depôt was at the works of MM. Clement et Cie., at Levallois, where arrangements had been made for recharging the batteries and effecting repairs.

As previously stated, there were three routes, each about 36 miles long, consisting of every variety of road, and including some very steep gradients. Each vehicle had to traverse each route three times. The total distance to be traversed was thus 335 miles; but to this must be added the extra distance due to the gradients, curves, &c. We have not thought it necessary to give these routes and gradients in profile, but have taken the actual distances covered and the times occupied.

Of the 12 competing vehicles seven completed the full course prescribed by the competition; these were Nos. 1, 3, 12, 13, 16, 23, and 25.

The Krieger Vehicles.

Excluding the only vehicle propelled by oil, viz., the No. 12, it will be seen that the remaining 11 electrical vehicles comprise three groups. In the first are the vehicles by M. Krieger, these are Nos. 1, 2, 3, and 16. In the second is No. 13, by the Compagnie Générale des Transports Automobiles, and in the third are those by M. Jeanteaud, Nos. 21, 22, 23, 24, 25, and 26. All these vehicles are alike in this respect, that they are all fitted with the Fulmen accumulator, which was fully described in our columns quite recently.* Dealing with the Krieger group we need only discuss Nos. 1, 3, and 16, as No. 2 is of a type now abandoned by M. Krieger. The other three are identical in their framing, &c., but have different bodies; thus these vehicles are interchangeable, a point of no small importance, especially as it enables a Victoria, suitable enough in fine weather, to be converted into a cab by merely shifting the body. The front wheels, which are of wood, are fitted with pneumatic tyres, but the rear ones have solid rubber tyres. The front part is double pivoted, each pivot supporting a 3-kilowatt motor, driving direct with helical gearing a spur rim on each wheel. The arrangement is extremely compact and simple and permits easy cleaning, access, and repairs. Two boxes containing the batteries are disposed in front and rear respectively and easily detachable. Each battery contains 22 Fulmen cells connected "in series," the type being marked B/17 plates, weighing 22 lbs. per cell. Each motor has a drum-wound armature enclosed within a four-pole field, of which two magnet bobbins are coarse wound (in the main current), the other two being in shunt.

No. 1 and No. 16.—Krieger.

No. 2 and No. 3.—Krieger.

No. 12.—Peugeot.

No. 13.—Cie. Gen. des Transports Automobiles.

The manœuvring of this vehicle comprises four distinct devices, viz.:—

(1) Hand-wheel steering gear.
(2) A lever "combinator" to effect the start, stop, and variation of speed.
(3) A foot-lever brake, cutting out the current when being applied (on rear wheels).
(4) A "bouton de recuperation," a button to be depressed by the driver's foot; this button excites the shunt winding and short circuits the series windings, thus braking the vehicle in a sense at whatever speed and position the combinator may be.

* *Vide* The Automotor, May, 1898.

No. 21.—JEANTEAUD.

No. 22.—JEANTEAUD.

No. 23.—JEANTEAUD.

No. 25.—JEANTEAUD.

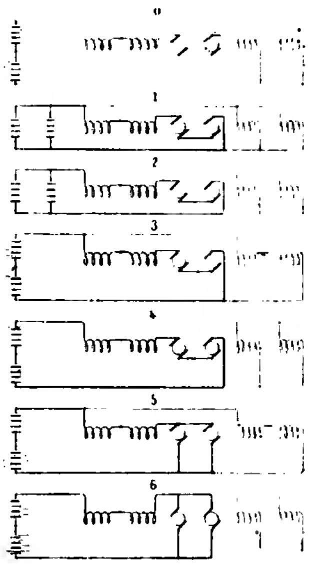
No. 24 AND No. 26.—JEANTEAUD.

No. 27.—MORGAN-SHERRIN.

For full braking the foot lever is used.

The various combinations are shown diagrammatically as under :—

KRIEGER "COMMINATOR."



THE COMPAGNIE GÉNÉRALE DES TRANSPORTS AUTOMOBILES VEHICLES.

In spite of the antiquated prejudice to the number 13, the Compagnie Générale des Transports Automobiles have not had ill luck with their No. 13 Coupé, conducted by its inventor, M. Jenatzy, but there is less originality displayed in this vehicle than in those of the other competitors; nevertheless, the vehicle behaved admirably, and so far it will hold the record as regards running with but one change of batteries. On June 10th this vehicle ran, after its ordinary 36-mile journey, another 27 miles before returning to the station. Without much attention to appearances M. Jenatzy places a box holding the batteries in front of the vehicle, which has front-steering wheels and rear-driving. These batteries consist of two groups of 22 B/21 Fulmen cells. There is one series wound motor, which revolves the intermediate shaft on which is mounted the differential box and a band brake acting both ways. M. Jenatzy has radically abandoned the recuperating method and the electric brake. The combinator is reduced to a simple handle turning round a vertical spindle and serving to interpose resistance of a varying quantity for starting and normal running. The vehicle can be made to run backwards at full speed—a doubtful advantage, we think, with a Coupé where the rear view is obstructed to the driver

Speed variations are effected by differently connecting up the batteries, which are grouped by 22, and may be coupled to slow speed (quantity), or full speed (tension), with the aid of a special commutator. For steep gradients a special mechanical speed reduction gear may be used to increase the power of the mechanism in the proportion of 100 to 67. Thus the carriage is pretty elastic in its governing and tractive power. For ordinary braking a hand brake serves, but a shoe brake may be applied to the rubbers. The handle operating this latter brake will doubtless be provided with an interruptor for the current; with the present arrangement inadvertently slackening, this brake might lead to an unpleasant experience should current be switched on.

We may mention that after the trials M. Jenatzy made a journey of no less than 92 miles with this No. 13 without recharging. This phenomenal run is, so far as we know, without precedent in the annals of electromobilism.

THE JEANTEAUD VEHICLES.

six vehicles, Nos. 21, 22, 23, 24, 25,

iron wheels with tangent spokes. and drivers. The wheels run on the efficiency of the manner in it rather original. There is one motor only, in front under the driver's seat driving the differential box, the shaft of which carries the aforesaid pivoted pins at either end, on which the wheels run. To enable the power to be transmitted when the wheels assume an inclined position, on a curve for instance, there are bevels keyed to each end of the shaft gearing into corresponding bevels on the wheels by means of interposed little bevel wheels, the axis of which latter runs in a vertical plane through the centre of the pivots. The energy is derived from a battery of 50 Fulmen accumulators, of 17 plates each, which are placed in two boxes, one in front and one in the rear. The motor has double winding which may be connected in different ways so as to vary speed For going backwards there is a special "reversing switch"; to start there is a foot lever which in its free position cuts the circuit out. Depressing this lever introduces gradually smaller resistances, and at full speed every resistance is thus cut out when the foot lever remains arrested by a latch. To manœuvre this carriage there are the following devices :—(1) A steering hand wheel; (2) a reversing switch; (3) a foot lever to start and slow down (resistance lever); (4) a combinator to effect variations in the connections; (5) a brake foot lever acting on a double direction brake; (6) a button, to brake electrically when proceeding at slow speed; and (7) a crank to operate the shoe brake on the tyres (pneumatics). The combinator of Coupé No. 21 has marks on the dial numbered from 0 to including 4, therefore indicating five distinct positions. When the indicator points to 0 the cells are in "tension" but isolated, the main windings on the field magnets, as well as the shunt windings, are in open circuit; the armature being short circuited; in this position the button connects the exciting shunt with the cells.

Mark 1 means slow speed. the batteries being "parallel" or coupled for quantity, the windings are both in circuit as also the armature, the button brake (electrical) does not act.

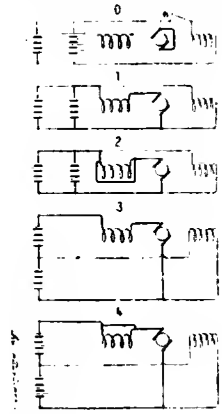
Mark 2 corresponds with a medium speed battery grouped in quantity; the main windings of the field magnets are short circuited; the shunt windings are "on current," so is the armature whilst electrical braking takes place.

Mark 3 means accelerating; batteries in "tension," everything "on current," the electrical brake does not act.

Mark 4 full speed, everything as before excepting that the main windings are short circuited, and the electrical brake again comes in play.

The combinations effected in No. 21 are as under :—

JEANTEAUD No. 21 "COMBINATOR."



Jeanteaud's (No. 24) Milord, as also Nos. 22 and 23, are similar to the No. 25 cab, which we describe below. Excepting No. 23 they showed certain defects in the accessibility of motor and batteries which in an everyday-use vehicle would be objectionable.

No. 25 cab is considered to be the best of the group. It is altogether an innovation as much from the carriage-builder's point of view as that of the engineer. To give the full benefit of the available space on a carriage to the passengers the batteries are boxed up in front like a Daimler motor. They are thus easily accessible and rest on the front shaft with their weight. The driver sits behind *à la* hansom. The weights thus being better distributed, the carriage can easily negotiate great gradients. Power is conveyed to the rear part and the driving of the rear wheels effected with chains. The motor has "drum winding," and is a two-pole one, having compound-wound fixed magnets. The batteries are in two groups of 22 each, and can be easily combined as required. The combinator shows clearly on a dial how the connections stand; whilst the combining is being effected a foot lever can be depressed, putting resistance in the main current so as to reduce the speed almost instantaneously. This resistance lever serves also for starting. The conductor has thus five parts to operate his vehicle :—(1) A steering hand wheel; (2) the combinator; (3) a foot lever actuating a hand brake; (4) the aforesaid foot lever for the starting resistance; (5) an emergency brake on the rubber tyres.

Jeanteaud's drojski, No. 26, is a small kind of carriage, the mechanism, however, is little different from his other cars.

In the combination of the cab No. 25, position No. 1 (minus) corresponds to going backwards; accumulators are "in quantity" main windings as well as the shunt, and the armature and the resistance are "on current."

No. 0 stop-braking, accumulators in tension but open, the main windings in circuit and on the armature; the shunt out of circuit the armature in circuit but reversed, the resistances in circuit for the electrical brake.

No. 1 (plus) slow speed, batteries in quantity, everything in circuit.

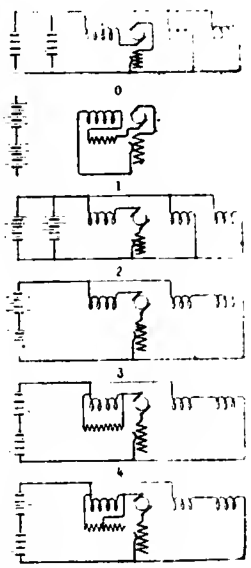
No. 2 medium speed, batteries in tension, everything in circuit except the resistance; from 1 to 2 it is impossible to go, owing to an automatic interlocker, unless a resistance be previously thrown in by means of the foot lever.

No. 3 acceleration, everything remains in its previous state except the main windings, which become shunted to two resistances, remaining in circuit, of course.

No. 4 full speed, as before, only that the main windings are shunted to one resistance, remaining in current as before.

In the vehicles Nos. 22, 23, 24, and 25 the combinations effected are thus :—

NOS. 22, 23, 24, AND 25 JEANTEAUD "COMBINATOR."



It was not to be expected that vehicles, while being tested under such severe conditions as those obtaining in this competition, would run without a certain amount of mishap, but what accidents did occur were for the most part very trivial and easily remedied—a fact which speaks for itself as testifying to the general good workmanship put into the various mechanisms. Thus, on the first day during the brake tests, No. 1 collided with a street orderly cart, and in so doing slightly damaged one of her pneumatic tyres and strained the motor. On the second day No. 2 had a hot bearing, and in some of the electric vehicles there was a little difficulty owing to faulty connections, and No. 2 had to replace a pneumatic tyre. On the third day several accidents of a minor character occurred. No. 23 had a burn out with the ammeter; No. 13 had a hot bearing, and had to stop half an hour to cool it; No. 21 had a bearing work loose, and had to return to the depôt. On the fourth day the Peugeot, No. 12, had to stop to replace a platinum ignition tube which had fractured, No. 23 developed a short circuit in the battery, and in No. 25 the controller gave out, while No. 27 had an accident with one of the pneumatic tyres. On the fifth day nothing more serious occurred than No. 21 having a burst pneumatic tyre. On the sixth day the vehicles ran admirably without a hitch. On the seventh day No. 24 was delayed through a burst tyre, as was No. 22, which also had some trouble with the rear wheels. On this day one of the London cabs put in an appearance and was allowed by the Committee to take part in the trial. On the eighth day No. 1 was delayed and damaged by a collision with a fiacre which was—as is not unusual in Paris—being driven at a reckless speed. The London electric cab, which was running remarkably well, unfortunately got one of its wheels in a tram rail and received some damage to the tyre. No. 16 had a burst pneumatic tyre, but completed the route with it. On the ninth day No. 1, while making a good run, stopped suddenly; it was eventually discovered that one of the battery connections had worked loose. On the tenth day No. 2 experienced a drop in the voltage and it was decided to return to the depôt; on arriving thither, however, it was found that the calibration of the voltmeter was faulty. A similar defect occurred with No. 22. The London cab had some trouble with the battery and had to return to the depôt. As this was the last day of the running trials all the vehicles were required to run a distance in order to exhaust their charges. On the eleventh day trials of traction and consumption were made with each vehicle, these were similar to those made on the first day. On the twelfth day, June 12th, the trials were concluded, and an excursion with the vehicles was made to Versailles, where the competitors, judges, officials, &c., dined.

In our tabular classification we have not grouped the petrol vehicles, as, although 10 were entered, only one, No. 12, actually competed. This was a neat and well-designed Peugeot; this vehicle went through its ordeal with every credit to its distinguished designer, and worthily upheld the faith that many people entertain in the suitability of petrol for ordinary town work. In its consumption tests this Peugeot came out very well; during a run of 36 miles the consumption of petrol was 3·63 gallons, or about $\frac{1}{10}$ gallon per mile. In ordinary daily work it is estimated that the consumption per day will be 4·4 gallons.

In addition to the foregoing, Messrs. Morgan and Co., of London, entered a 4-seated phaeton, officially known as No. 27, and equipped with 60 Sherrin cells, the weight of the battery being 1,980 lbs., and the total weight of the vehicle being 5,940 lbs. It, however, only ran during part of the trials, and has therefore been excluded from our analysis.

Tables Nos. 1, 2, and 3 (p. 382) give the numbers, weights, &c., of the vehicles that actually took part in the competition.

THE ACCUMULATORS.

In an accumulator destined for service in electromobiles a great specific power (watts per pound of total weight), and also great specific energy (watt hours per pound of total weight) are primordial qualities since we have to diminish the dead weight as much as possible so as to enable us to carry useful loads through long distances without recharging.

We give here the data relating to the Fulmen cells as these, as before stated, were employed by all the competitors in the competition.

The Fulmen type B/13 comprises 13 plates, of which six are positive. They are of rectangular shape, about $7\frac{1}{4}$ inches high, $4\frac{3}{4}$ inches wide, and barely $\frac{3}{16}$ inch thick. They have rectangular meshes (24 in each) in which lodges the active substance.

The following are the weights respectively of plates and their frames :—

	Positive plate. lbs.	Negative plate. lbs.
Frame	·297	·297
Active material	·749	·561
Total weight	1·046	·858

The specific figures of each element are as follows :—

Specific output, in ampères	per lb.	1·37
Useful specific power, in watts	"	2·41
Specific capacity, in ampère hours ..	"	6·60
Useful specific energy, in watt hours ..	"	11·80
Specific weight, in lbs. per kilowatt ..	..	418·0
" " " " hour	..	825·0

At the rate of 5 watts per kilo (= ·454 watts per lb.) the Fulmen

cell will store more than 25 watt hours per kilo (= 11·4 watt hours per lb.). These figures suffice to enable one to calculate the necessary battery power and weight to run a motor-vehicle of a given weight, distance, speed, &c., on a given gradient.

Doubling the rate of discharge to 4·54 watts means lowering the specific energy to 9 watt hours per lb.

The surface of each plate is 27·1 square inches, the total surface presented being 325·5 square inches for the six positive plates. The celluloid casing and the distance pieces between the two plates adjoining, weigh 1 32 lbs. Each element thus weighs 16·53 lbs., and is considered to have a normal rate of discharge of 21 ampères, corresponding to a continuous discharge for 5 hours, which gives a current density of 1 ampère per 15·5 square inches, or ·0645 ampère per square inch. The discharge may, however, be as high as 50 and even 100 ampères for a short time. With the normal rate the D.P. is 1·9 volts per element and the capacity 105 A.H.'s. Each element has thus an available energy of 200 W.H.'s.

The following table gives the particulars of the Fulmen cells :—

	Number of plates in each cell.				
Each cell or element	9	11	13	17	21

Capacity in ampère hours for normal discharge of five hours	70	85	105	140	175
Energy in watt hours.. ..	133	160	200	266	333
Weight.. .. .. lbs.	11·6	14·3	16·9	30·8	39·7

In order to form an accurate idea of the performances, we must know the amount of energy supplied to each vehicle; this is given in Table 4 (p. 384).

Generally the observations as to speed, consumption, &c., were made over a range embracing at least four speeds. Although the data so obtained is exceedingly valuable, we have confined our attention to two speeds for each vehicle, viz., those most likely to be used in actual work. The results obtained are tabulated in Table 5.

Special trials were made of the capabilities of the vehicles to ascend gradients, and the well-known Mont Valerien was selected for this test; the results obtained are given in Table 6 (p. 384).

The final tests were the brake tests. The importance of good brakes on vehicles in cities such as Paris, in which there is a rapid street traffic and many steep gradients, cannot be overestimated. As will be seen, those brake tests were of a very complete character; the results are given in Table 7 (p. 384).

It will, we think, be admitted that these trials are of an exceedingly interesting and valuable nature, because the data supplied has been so very voluminous. With the aid of these tables, those intending to start cab services in any town in which there is an abundant supply of current will have no difficulty in selecting the most suitable type of vehicle, motor, and cell. The last is perhaps the most important. So far, the Fulmen cells have given very remarkable results as regards endurance, and this latter, we need hardly remind our readers, is the crux of the whole problem, as upon a low cost of maintenance hangs the whole question of electric cabs in preference to other motor-vehicles.

THE AWARDS.

The jury assembled on the 18th ult. at the Automobile Club to consider their report and to make the awards. M. Forestier presided. The sum available for prizes was 3,000 francs, of which 2,000 were subscribed by the Compagnie Générale des Petites Voitures, and 1,000 francs by the Chambre Syndicate des Entrepreneurs des Voitures. After considering their report the jury recommended the following distribution :—

In the first category, for two-seated cabs :—First prize, 1,000 francs: Jeanteaud No. 25; second prize, 600 francs: Jenatzy No. 13.

In the second category, for four-seated vehicles with roof for luggage :—First prize, 1,000 francs, Krieger No. 16.

The balance of 400 francs was awarded to those conductors who had exhibited special skill in the conduct of their vehicles. They were :—100 francs to M. Démény, conductor of No. 16; 100 francs

to M. Pascal Bailly, conductor of No. 21; 100 francs to M. Creux, conductor of the Peugeot No. 12; and 100 francs to M. Alary, conductor of No. 20.

The Committee expressed their regret that under the conditions of the competition they were unable to recommend the Peugeot No. 12 in consequence of its consumption being too high. In other respects they express a high appreciation of the vehicle for its regular running and its good working.

The Petroleum Flash Point in Holland.—The Dutch Minister of Commerce has appointed a Commission to inquire into and report upon the advisability of regulating by law the "carriage, storage, sale, and employment" of petroleum in Holland. The Commission consists of six members, of whom two are officials in the Department of Commerce, two University professors, one a member of a firm of public warehouse proprietors, and one a lawyer and member of Parliament. The last-named, Mr. M. J. Pynappel, of Amsterdam, is Chairman of the Commission. The two professors appointed are Professor C. A. Lobry de Bruyn, of Amsterdam University, and Professor Hoogewereff, of the Polytechnical School, Delft. The former, a celebrated chemist, has taken an active part for some years in the agitation to get the standard of flash point raised on the Continent.

ON DIFFERENTIAL GEAR.

ALTHOUGH the "jack-in-the-box" forms an integral part of the mechanism of the great majority of motor-vehicles, its action seems to be but little understood either by mechanics or users. As we constantly receive letters asking for information on this subject, we propose in the present article to discuss the salient features of this beautiful piece of mechanism. The differential gear is an example of an epicyclic train, which is any system of toothed gearing, the axes of which revolve around a common centre. This gear is a modification of the well-known sun and planet motion. As constructed in its usual form it consists (*see* Fig. 1) of a pair of bevel wheels placed on either side of a carrier, the two wheels they engage with on either side being secured on independent but concentric axles, the latter forming the shaft or driving axle of the vehicle. Referring to the drawings, the carrier, B B′, consists of two dished casings having

that is, certain of their teeth engage with teeth on Q Q and the whole rotates. Observe that in this case P and P do *not* rotate.

Suppose now that the wheel, Q, is fixed. As C is rotated, the wheel, P, rolls around Q and turns Q′, that is, Q′ makes two revs. for each one of C. When a vehicle is following a straight course the bevel wheels, P and P′, act, as before stated, as keys, and the wheels, Q and Q′, rotate at the same speed as C. When turning a curve, as is well known, the outer wheel has to follow a path of much larger radius than the inner one, that is, the outer wheel in order to pass over a certain path in the same time as the inner wheel revolves faster, that is, the bevel wheel geared to that outer wheel will be rotating faster than the bevel wheel geared to the inner driving wheel—that is, there will be a *difference* (*sic*) between their speeds; this difference causes the wheels, P and P′, to turn about their axles, and the speed at which they turn will be that due to the difference of the speeds of the two wheels, Q and Q′. Hence the term "differential gear."

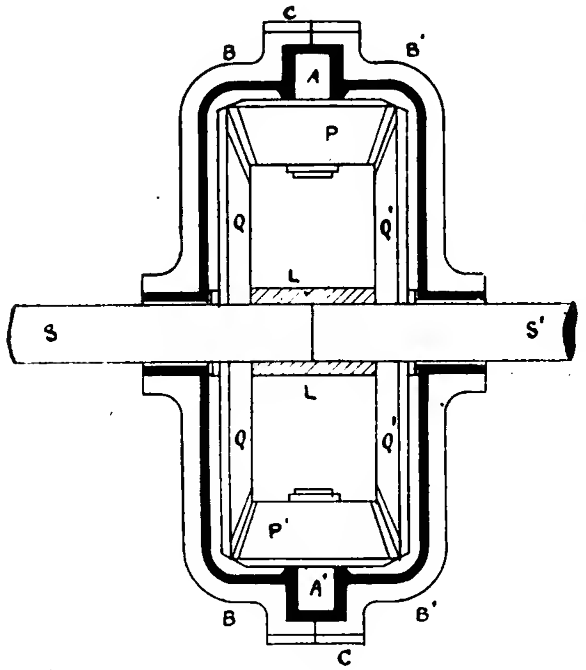

Fig 1

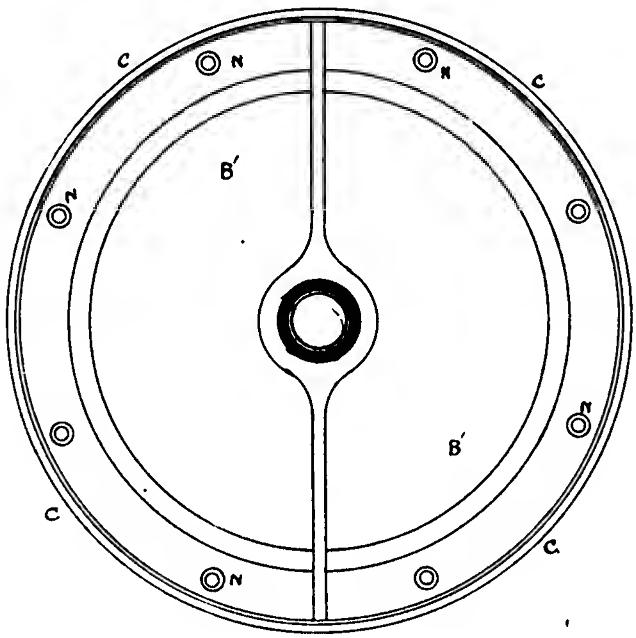

Fig 2

Differential Gear for Motor Vehicles

G.H.L del

bosses at two diametrical points in which are keyed two stalks, A A′, on these latter are mounted the bevel wheels, P P′, which are free to revolve. In the centre of each casing is a boss through which, suitably bushed, pass the shafts, S and S′; to these latter are rigidly keyed the two mitre wheels, Q and Q′. The two ends of the shafts which abut inside the casing are enclosed in the sleeve, L L, so as to afford additional support, and this sleeve also acts as a distance piece. It is, of course, not an essential fitting. The parts having been assembled the two parts of the casing, B and B′, are bolted together (*see* Fig. 2) by nuts and bolts, N N, &c. On the periphery of this casing teeth are cut, C C, or the surface may be left smooth for belt driving. On the outer extremities of the shafts, S and S′, are the chain sprocket wheels, which transmit the motion to the driving wheels. It is thus understood that the power from the motor is transmitted by teeth or belt gearing to the pulley, C C, which revolves at a speed and power varying directly with those of the motor. So far we have a positive transmission.

This power is distributed equally to the two metre wheels, Q and Q, and through them to the sprocket wheels. In this case the small bevel wheels, P and P, act merely as keys or feathers,

It should be observed that it is not necessary to have the two wheels, P and P′, one would suffice, but two and even three are used in order to ensure proper distribution of stress. Neither is it necessary that any particular ratio should exist between the diameter of P and Q. The present generally accepted design is based entirely upon mechanical considerations.

A study of the theory epicyclic gears will prove an intellectual pleasure of no mean order, and we can recommend it. A few models should be employed, so that the various motions can be observed. It is not a bad test of the knowledge of a motor-vehicle engineer to ask him to explain the differential gear. Before concluding, we must refer to an article on the subject which appeared lately in *La France Automobile*, in which the writer tried to demonstrate the evidently erroneous contention that the wheels, P P′, would turn round on their axles, A A′, on a straight course, when the two drivers (car wheels) happen to run on a track, greatly differing in the state of surface, from one side to the other.

It is clear that, even if it were imaginable that one wheel runs on a rail, whilst the other hammers over fresh macadam as long as the carriage steers a straight course the bevels, P P′, can *not* rotate;

provided that the wheel on the rail does not slide and become dragged along.

It must be remembered that, under such conditions as stated, a straight course can only be run by counteracting the difference in adhesion of track by the steering gear properly handled, otherwise the carriage would tend to run round, the resistance being greater on the inner side than on the outer. So long as the resistance to traction is uniform for both paths traversed by the wheels the drivers will revolve at equal velocities, in which case the bevels, P P′, will not revolve on their axes.

G. H. L.

ELECTRICAL TRACTION COEFFICIENTS, WEIGHTS OF ACCUMULATORS, &c.

M. Hospitalier in the course of a series of articles on the above data contributed to our excellent contemporary, *La Locomotion Automobile*, says :—

As will have been seen from previous notes, while awaiting better, we can dispose of accumulators of which the specific power is five watts per kilogramme and the specific energy 25 watts per hour per kilogramme. These figures serve as a basis of our subsequent calculations, and, in order to determine the power of the motor and the weight of the accumulators to be carried, one must understand the traction coefficient. This traction coefficient is extremely variable, according to the nature of the ground, its maintenance in repair, speed of the vehicle, direction of the wind, system of running, nature of tyres, &c.

For an automobile limiting its actual work to a town service, it is necessary to take its maximum speed on the level at 18 kilometres per hour, that is to say, 5 metres per second, and suppose that running sometimes on a wooden pavement, which gives a very feeble traction coefficient, sometimes on an ordinary muddy pavement, which furnishes a high traction coefficient, the vehicle working during the whole journey with a medium coefficient of 2·5 per cent., or 25 kilogrammes per ton. On inclined planes the coefficient is increased, but by reducing the speed on the one hand and by forcing the normal duty of the accumulators on the other, the strain can be counterbalanced and kept within the limits indicated, as in the descents the expense is less, sometimes nil.

In order to bring out the calculations for a vehicle, of which the total weight (in working order) is 1 ton, it will suffice to multiply the quantities we are about to establish by the total weight of the vehicle in tons, so as to determine the corresponding value of a vehicle of a given total weight.

With a traction coefficient of 2·5 per cent. and a speed of 5 metres per second it is necessary to supply the vehicle with an effective power to the peripheries of the wheels as follows :—

$25 \times 5 = 125$ kilogrammetres per second (per ton), or 12·5 poncelets, or about 1,250 watts.

Electric motors could be easily built now of which the output between a full and a half charge would be about 80 per cent. With a loss of 10 per cent. in the transmission between a quick angular speed and the wheels of an angular speed relatively weak, the output would be—

$$0{\cdot}8 \times 0{\cdot}9 = 0{\cdot}72 \text{ per cent.}$$

The electric power actually furnished to the motor by the accumulators will then be—

$$\frac{1{\cdot}250}{0{\cdot}7} = 1{\cdot}800 \text{ watts (per ton).}$$

In order not to exceed the rule of 5 watts per kilogramme it is necessary to put on a total weight of 1 ton—

$$\frac{1{\cdot}800}{5} = 360 \text{ kilogrammes of accumulators, or 36 per cent.}$$

With a less weight the rule is strained and the battery overworked. With a greater weight the journey is prolonged without re-charging, but the disposable weight is reduced for a four-wheeler motor, transmission, and passengers.

Practically, the proportion of the accumulator weights to the total weights of an electromobile is always comprised normally between 30 to 40 per cent. It has been demonstrated elsewhere that there is no advantage in putting on a vehicle heavier accumulator weights than 50 per cent. of the total weight, as, if that is done, the utilisation of the battery would have to be reduced. What road could be travelled over under these conditions? It is easy to ascertain that from what is already known.

If, at a speed of 18 kilometres per hour, 1,800 watts is expended, the expenditure in one hour would be 18 watts per hour in running 18 kilometres, or, practically, 100 watts per hour per ton kilometre.

In the experiments made by Messrs. Morris and Salmon, of Chicago, the real expenditure varied between 84 and 92 watts per hour per ton kilometre, but Chicago is a flat country, and the experiments were made under evidently favourable conditions.

The accumulators, including 25 watts per hour per kilogramme, representing five hours' run, could, under a special hypothesis, furnish current for a total distance, without recharging, of 18·5 = 90 kilometres.

If the stoppages, bad working, descents, &c., are taken into account, these figures can be reduced by 30 to 35 per cent., and it can then be summed up by saying that the actual accumulators permit us, without forcing their normal rates, to communicate a speed of 18 kilometres per hour on the flat, and to make it run 60 kilometres without recharging, on condition that the weight of the accumulators represent 36 per cent. of the total weight of the carriage, and that the vehicle remains on the same level at the end of the journey, without performing extravagant gymnastics on inclined planes and broken up roads.

The fact must not be lost sight of that the raising of a ton to 100 metres height represents 100,000 kilogrammetres, which correspond with 143,000 kilogrammetres at the terminals of the accumulators, and these 143,000, equivalent to 400 watts per hour, that is, 100 watts per hour per ton kilometre, reduces the run to 4 kilometres. The increasing of the traction coefficient, resulting through the bad state of the roads and climatic conditions, has also an enormous importance, difficult to figure out, and it is not astonishing if these many causes (to which must be added the inefficiency of a conductor who lets the brake press on the wheels, or manipulates the connections badly, which wastes the energy uselessly) lead, above all at the beginning, to impede the anticipated runs. The conductor of an automotor requires a certain amount of practice before he becomes an expert.

EXPLOSION OF A TUBE IN A STEAM TRAMCAR BOILER.

The following is an excerpt from the official report of an inquiry held by the officers of the Board of Trade under the Boiler Explosions Acts, 1882 and 1890, to determine the cause of the explosion of a Field tube in a tramway engine boiler at Prettywood, Lancashire, on February 15th last.

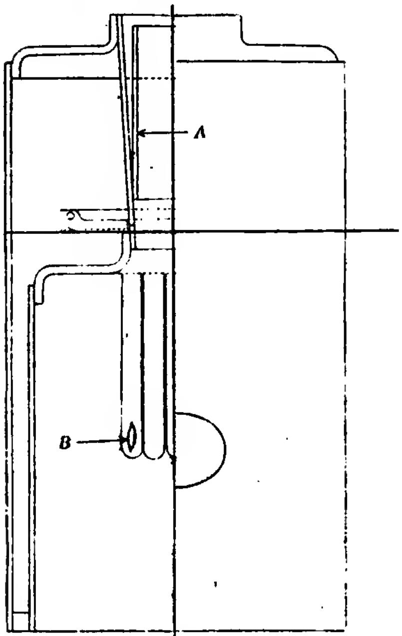
The boiler was made by Messrs. Green and Sons, of Smithfield Ironworks, Leeds, about 1884, for the Bury, Rochdale, and Oldham Tramways Company. It is of the cylindrical vertical type. The shell is 6 feet high and 3 feet 6 inches in diameter. It is made of two steel plates, ½ inch thick, the vertical seams of which are of the lap description, and double riveted with ¾-inch rivets spaced about 2¼ inches apart. The crown is flat, and formed of one steel plate, ⅝ inch thick, flanged to suit the shell and uptake, and connected to them respectively by a single row of rivets.

The firebox is about 3 feet 8 inches high and 3 feet in diameter. The cylindrical portion is made of one wrought-iron plate, $\frac{7}{16}$ inch thick, the vertical seam being welded. The lower end is attached to the shell by a single row of rivets, with a distance ring of wrought-iron between, 2½ inches by 2 inches in section, giving a water space of 2 inches at the bottom. The crown of the firebox is flat, and formed of one wrought-iron plate, ¾ inch thick, and is flanged to fit the top of the cylindrical part of the firebox and the bottom of the uptake in the usual manner.

The uptake is made of one wrought-iron plate, ½ inch thick; its vertical seam is welded, and it is attached to the shell and firebox crowns by single rows of rivets. A wrought-iron parallel tube (marked A on the sketch) is placed inside the uptake, and the space between this tube and the uptake is filled with fireclay, to prevent over-heating of the uptake.

There are 79 Field tubes, 2¼ inches diameter, by about $\frac{3}{32}$ inch thick, fitted in the crown of the firebox. Sixty-four of these are about 24 inches long, and the remaining 15 in the way of the fire-door are about 17 inches long. A pipe about $1\frac{1}{4}$ inches diameter and 1 inch shorter than the tube, is placed inside each tube, for circulating purposes. These inner pipes have conical-shaped pieces at their upper ends, with three ribs, which rest on the open ends of the tubes, and keep the inner tubes central with the outer tubes, a space being thus left for the circulation of the water in the tubes. A circular scale pan is placed round the bottom of the uptake on the water side for preventing priming and collecting impurities contained in the water.

FIG. 1.



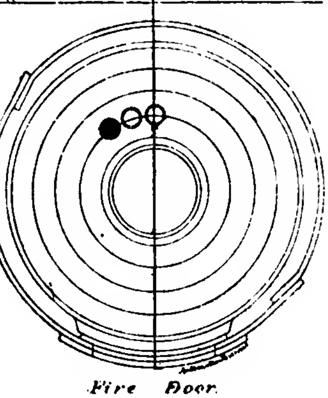


FIG. 3.

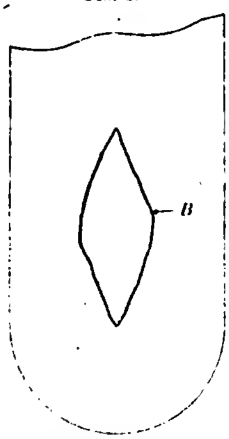
FIG. 2.



Full size view of end of tube, and fracture

The boiler was fitted with the following mountings :—

One steam-pressure gauge, graduated to 200 lbs.
Two safety valves, $2\frac{1}{2}$ inches diameter, loaded by direct springs to 140 lbs. per square inch.
Two glass water gauges.
One steam stop-valve.
One governor steam valve.
One car-brake steam cock.
Two feed check valves.
Two injectors.
One blower cock.
One blow-off cock.
One filling plug.

During its life the boiler had been frequently examined and repaired. It was partially re-tubed in 1887, 1888, and 1889, and in 1891 it was tested to 200 lbs. per square inch. In 1892 the boiler was again tested by water pressure to 200 lbs. ; two new stays were also fitted to the right-hand side of the firebox, and 58 tubes were renewed. In 1893 the boiler was again tested twice by water pressure, in January to 230 lbs., and in November to 220 lbs. A patch and four stays were also fitted to the right-hand side of the firebox, and 32 tubes were renewed. In 1894 42 tubes were renewed. In 1895 the boiler was twice tested by water pressure, in February to 230 lbs., and in October to 250 lbs. ; the patch fitted in 1893 was replaced by a larger one, and 45 tubes were renewed. In 1896 the boiler was tested by water pressure to 230 lbs. in October, and 31 tubes were renewed during the year. In July, 1897, it was tested to 250 lbs., and 36 new tubes put in. It was neither insured nor inspected by any company. It was cleaned out about every 12 days.

The explosion occurred at about 6 p.m. on February 15th, while the car was proceeding from Heywood to Bury. Fortunately no one was killed, but the driver was injured in leaping from the vehicle. The tube that exploded was one of the "Field" tubes, at the point marked B (*see* Figs. 1 and 2). The aperture was about 2 inches by $\frac{3}{4}$ inch. The steam and water escaped through it with such violence as to extinguish the fires.

The explosion was caused by the wasting and deterioration of the material composing the tube, through frequent overheating, to about $\frac{3}{32}$ of an inch, or half its original thickness, thus rendering it unable to withstand the ordinary working pressure. The scale where the fracture took place was about $\frac{1}{16}$ of an inch thick, but 6 inches higher up the scale was about $\frac{1}{4}$ inch thick. The pressure just prior to the explosion was about 135 lbs. per square inch. In his general remarks the inspector, Mr. Jas. Wishart, says :—

"The boiler is about 14 years old, and is known on the Company's books as No. 29, but no record of repairs or renewal of tubes appears to have been kept until about three years after it became the property of the Tramway Company. Since 1891 the boiler does not appear to have been completely re-tubed, but the number of new tubes fitted each year varied from 31 to 58, or an average of about 35 per annum. This shows that the number of new tubes put in since the boiler was re-tubed in 1889 would have been sufficient to have completely re-tubed it a little over three times. The average life of a tube would, therefore, appear to be about two years and two months. The tube that failed in this case was put in in May, 1896, and has consequently been in use for only one year and nine months, or five months less than the average lifetime of a tube. The position of the tube in the boiler and the quality of the material of which it was made would, no doubt, very largely affect its lasting properties, so also would the attention it received by cleaning. The Company's locomotive foreman stated that occasionally new tubes have to be removed owing to some inherent defect that had developed after the tube had been in the boiler only for a short time. The Company's servants appear to have exercised a reasonable amount of care in their examinations, as most of the tubes taken out were observed to be defective owing to slight leakage or bulging, but others had been removed on suspicion of being worn out. Compared with the number that the firm have voluntarily removed from time to time, those that have given way and become subject to inquiries under the Boilers Explosions Acts are fortunately very few. A thorough examination of the boiler was made in July, 1897, when it was tested by water pressure to 250 lbs. per square inch, and since then it has been subjected to the usual periodical cleaning and examination every 10 or 12 days.

"The man who drove the engine on the day the tube gave way was not one of the regular drivers; he was only employed on relieving duty."

In his comment on the above the Engineer-in-Chief of the Board of Trade, Mr. P. Samson, M.I.M.E., &c., remarks :—

"This is another explosion resulting from the wasting of the lower portion of a Field tube until it was no longer able to withstand the ordinary working pressure.

"It seems the interior of the tube was coated with scale ranging in thickness from $\frac{1}{16}$ inch to $\frac{1}{4}$ inch. This resulted in the end of the tube being frequently overheated, and the wasting of the material above described was brought about in that way.

"Such tubes are difficult to clean or to examine, and although this firm appears to have had considerable experience with tubes of this type and to have in force a system of periodically examining them, there still seems to be room for improvement in dealing with them."

AUTOMOBILE ASSOCIATION (LIMITED).

A new Company, under the title of the Automobile Association (Limited), has opened premises at 1 Princes Road, Holland Park Avenue, London, W., where it will in a few weeks have on view a large variety of automobile carriages. We understand that this Association has secured some of the very best examples recently exhibited at the Paris Exhibition, and that it will be able to suit the requirements of every automobilist by the varied selection which it will be able to provide. The vehicles will have a seating capacity ranging from one to 12 people, and from 1¾ to 8 H.P., the prices ranging between 70 and 700 guineas. The directors will also, in about a fortnight's time, have a new motor-cycle ready, constructed after the Hille patents, one of the special features being a greatly improved carburettor. One of these tricycles won the first prize at the Berlin-Leipzig race, and the makers state that it will travel at 20 miles per hour, and take hills up to 15 per cent. at a speed of 7½ miles, with a 1¾ H.P. We hope to give our readers more detailed particulars in one of our forthcoming issues of the various novelties which this Company is introducing.

THE WEIDKNECHT AND BOURDON STEAM OMNIBUS.

Among the vehicles assembled under the auspices of the Motor-Car Club in London on the 8th ult., when Mr. H. J. Lawson gave his interesting demonstration of the possibilities of the motor-omnibus, the Weidknecht Omnibus (*see* Fig. 1) attracted considerable attention by reason of its size and appearance. Riding on the top of an omnibus in the fine weather is a cheap and by no means unenjoyable way of obeying the doctor's injunctions to "take carriage exercise." Our buses have emblazoned inside them the legend, "Constructed to carry 26 passengers, 12 inside and 14 out." The Weidknecht can carry, or rather has accommodation for, only 16 passengers, and these have to be carried inside. On the other hand, it can carry in addition 1,100 lbs. of baggage on the roof, this gives an average of 70 lbs. for each passenger; it would thus make an excellent railway station omnibus. This vehicle weighs 4·7 tons (light), which is 1·7 tons above the limit allowed by the Locomotives on Highways Act. It is also too wide, being 7 feet 10 inches between axle centres. It is thus not legally suitable for traffic in this country. For our own

Fig. 1.

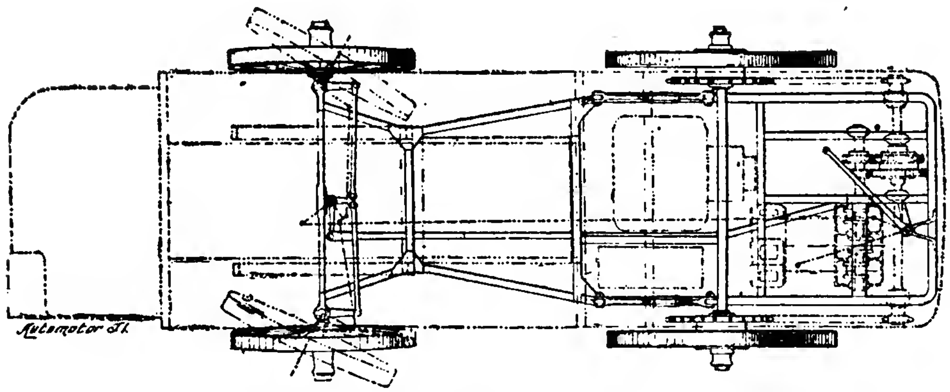


Fig. 2.

part we think that on the weight of the Weidknecht a much more elegant and commodious vehicle could have been designed.

As, however, it is a completed machine, and such vehicles are

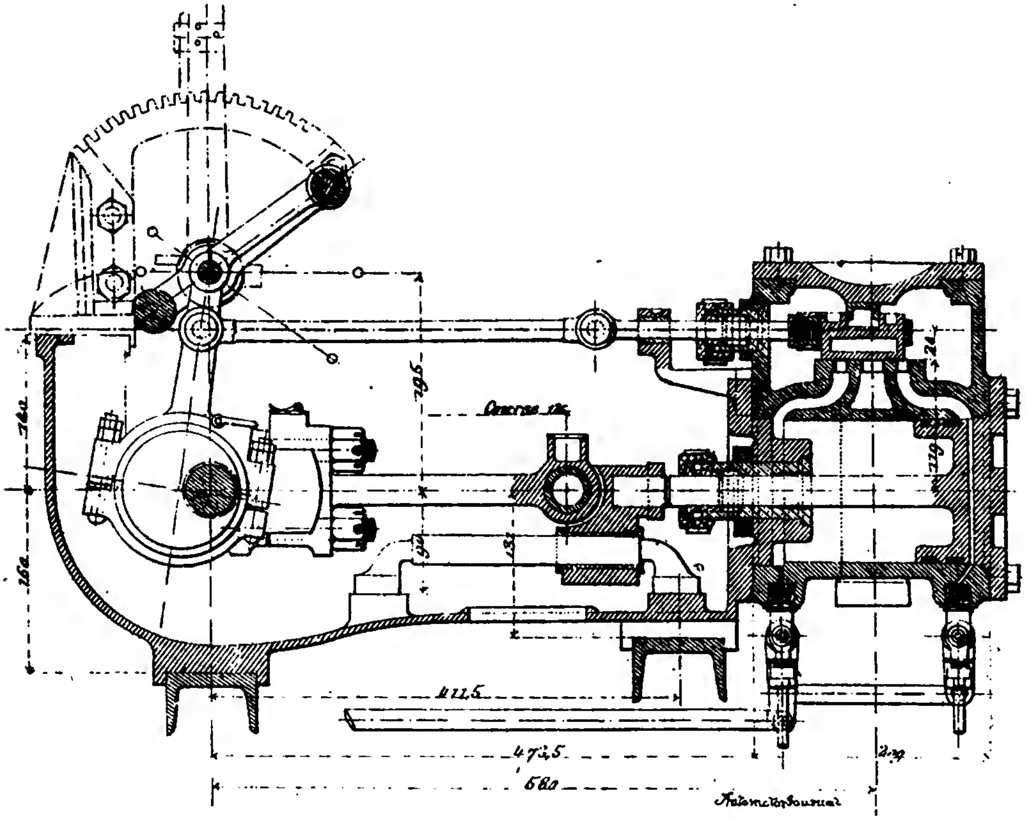

FIG. 3.

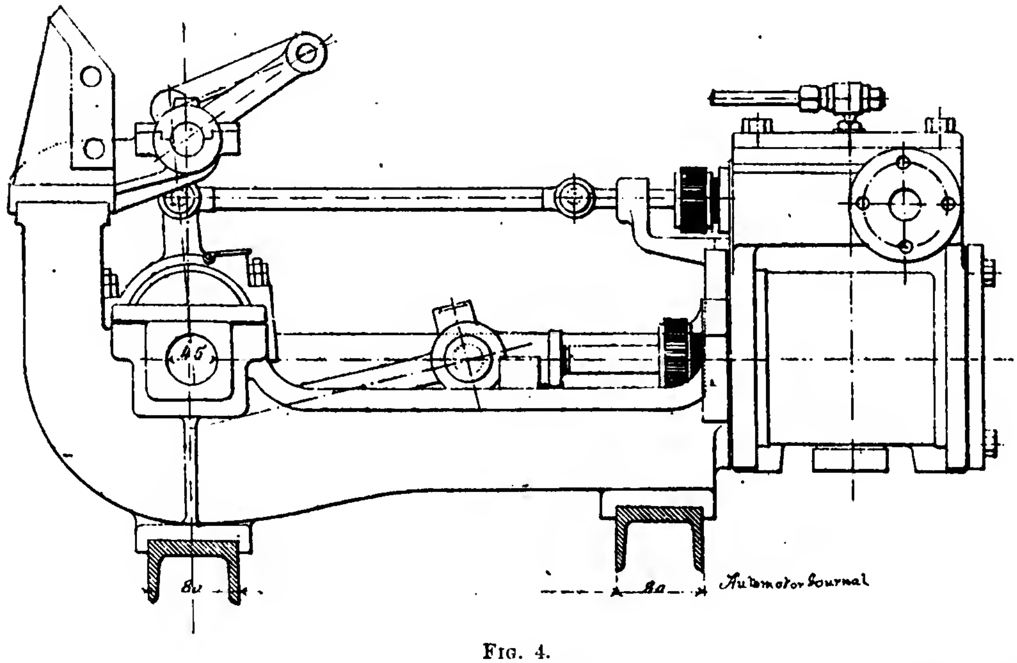

FIG. 4.

worked continually, economically, and profitably in France, and as we have been asked to describe it we accordingly do so. This vehicle represents the latest type of omnibus built by M. Weidknecht. It will be remembered that this gentleman entered one at Les Poids Lourds competition at Versailles of last year, and known officially as No. 4,* but owing to a breakdown it had to retire. The present omnibus differs in some respects from No. 4, chiefly in that it carries no passengers on the roof. The type and arrangement of the machinery are, however, the same as in the former. The framing (*see* Fig. 2) consists of two channel girders which, instead of being parallel throughout their length, are bent inwards at their rear ends, upon which is mounted, through ordinary plate springs, the rear axle which constitutes the steering axle. On the fore part of these girders is a platform upon which is carried the boiler, machinery, coal bunkers, feed tanks, &c., all this weight being carried on the fore axle by means of springs, &c. On this fore axle, too, are the driving wheels. The body of the vehicle is mounted upon springs, much in the same way as in an ordinary wagon, but underneath the fore part of the body and on each side are two compensating springs. The object sought to be attained in having the driving wheels in front and directly under the mechanism, and in supporting the body by an elaborate arrangement of springs, is said to be the maintenance of an invariable weight on the drivers, whether any load is being carried or no. Whether this is effected or no we have no means of saying. The idea is, however, good, and the design original. The total length of the vehicle is 18·04 feet, of which 7·56 feet are occupied by the front platform. A roof extends over the whole vehicle and upon this is carried the baggage, 1,100 lbs.

The boiler has previously been illustrated and described in THE AUTOMOTOR.† It is of the vertical internal firebox type, having 87 inclined water-tubes, each 1·18 inches in external diameter. The grate area is 3 square feet, and the heating surface 64 square feet. The boiler will evaporate 572 lbs. of water per hour, and the normal consumpt is 10·7 lbs. of coke and 7 gallons of water per mile.

The chimney projects through the roof, and is fitted with a silencer which effectually prevents the noise due to the exhaust. The feed is either by

* *Vide* THE AUTOMOTOR, August and September, 1897.

† May, 1898.

a Sellar's injector or by a pump driven off the intermediate shaft.

The motor (*see* Figs. 3, 4, 5, 6, and 7) consists of two horizontal high-pressure engines, each cylinder being 4·92 inches by 4·92 inches stroke (*see* Figs. 3, 4, and 5). The steam distribution is effected by a "Soims" valve gear, which permits a varying cut-off of from 10 to 83 per cent. of the stroke. At the normal speed the engines run at 350 revs. per minute, and give off 19·7 H.P. The motor shaft gears with an intermediate shaft, upon which is mounted a differential gear. On each shaft are two pinions, operated by levers and clutches in the ordinary way, the two speeds obtained being 4·6 and 9·3 miles per hour. On the extremities of the intermediate shaft are the chain pinions, which by means of chain transmit the motion to the drivers; these are 4 feet 7 inches diameter, and are mounted on bronze-bushed axles. The steering is effected, as before said, by the rear wheels; these are mounted on pivoted axles, and are joined by Ackermann's gear to a central rod, which is cogged at its fore end and gears into a vertical spindle having a steering wheel at its upper extremity.

Fig. 5.

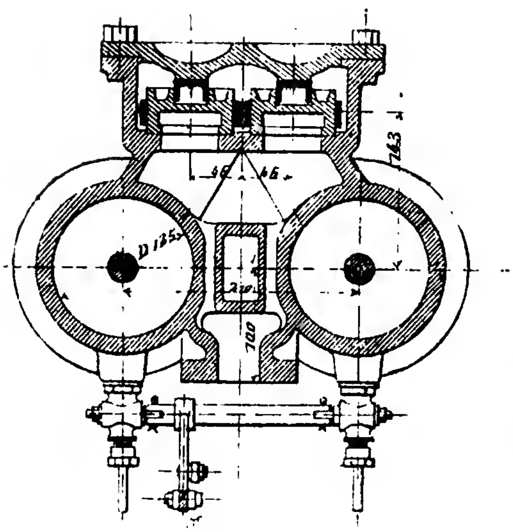

Fig. 6.

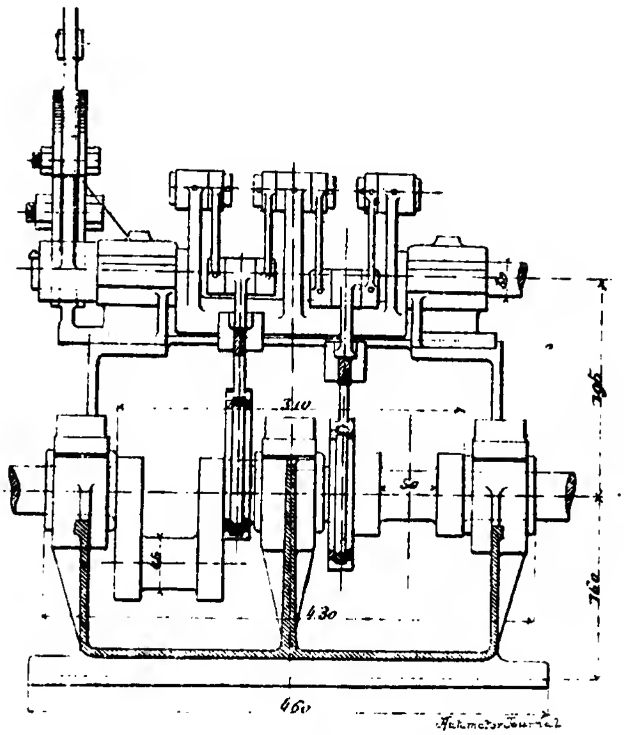

Fig. 7.

There are two brakes—a Lemoine coiled-wire brake and an ordinary shoe brake worked by a screwed lever. The tyres on the drivers are 3·74 inches wide. The following are the weights :—

Weight, empty	10,560 lbs.	
„ of water in boiler	286 „	
„ „ in feed tank ..	616 „	
„ fuel	132 „	
„ staff and sundries ..	286 „	
Useful load	3,520 „	
Total weight on drivers	7,700 „	
„ „ rear wheels ..	7,700 „	
„ „ in working order ..	15,400 „	= 6·87 tons.

THE PARIS EXHIBITION, 1900.

THE Royal Commission of the Paris Exhibition, 1900, have now issued the official particulars and classifications for exhibitors. Forms of application are also ready, which can be had upon application to the Secretary, Colonel Herbert Jekyll, C.M.G., St. Stephen's House, Westminster. The grouping and classification has been very carefully drawn up.

Motor vehicles are included in Group 6 (civil engineering, transportation), Class 30 (carriages and wheelwrights' work, vehicles other than those used on railways), which includes "private and state carriages, sledges, sedan chairs, public carriages, ambulance vans, carriages for invalids and children, carts for all purposes, vans and drays, vehicles propelled by mechanical means, cycles, parts of carriages, materials and inventions connected with carriage building, wheelwrights' work and cycle manufacture."

Under Class 32 are tramways, including "various types of permanent way used on different kinds of roads; points and crossings, turntables, turning loops and triangles; implements used for track laying, cleaning, &c. Cars drawn by animals; locomotives and automobile carriages; rolling stock for tramways propelled by mechanical means; brake gear; plant used for storing power (hot water, compressed air, electricity, &c.)."

The special committee appointed for these groups comprise:—Sir Thomas Sutherland, G.C.M.G., M.P., chairman; Lord Kelvin, G.C.V.O.; Lord Claud J. Hamilton; Lord Pirbright; Right Hon. William L. Jackson, M.P.; Sir Edward H. Carbutt, Bart.; Sir James Kitson, Bart.; Sir John Wolfe-Barry, K.C.B.; Sir Courtenay E. Boyle, K.C.B.; Sir William H. White, K.C.B.; William H. Preece, Esq., C.B.; Henry Cosmo Orme Bonsor, Esq., M.P.; William Crawford, Esq.; William D. Cruddas, Esq., M.P.; Francis C. Danson, Esq.; James Staats Forbes, Esq.; Joseph Holman, Esq.; Thomas H. Ismay, Esq.; Wyndham S. Portal, Esq.; Paul Rottenburg, Esq.; William D. Stephens, Esq.

PNEUMATIC v. IRON TYRES.

IN a paper read before the Société des Ingénieurs Civil, by Mr. Michelin, this gentleman gives the results of some carefully conducted experiments made by him to determine the relative qualities of pneumatic and iron tyres.

Mr. Michelin used for his registering apparatus a dynametric spring, formed by two articulated plates at one end of the apparatus; one fixed to the vehicle and the other to the whiffletree. With this was used an automatic registering device.

The first experiments were made with iron and pneumatic tyres of the following diameters and weights:—

Kind.	Diameter of Wheels. Front.	Back.	Weight of Wheels. Front.	Back.	Weight of Empty Vehicle.
	ft.	ft.	lbs.	lbs.	lbs.
Iron tyres ..	3·02	3·67	127·6	158·4	1269·4
Pneumatic tyres	2·95	3·93	85·8	123·2	1192·4

To the weight of the empty vehicle the weight of the driver must be added; and to make this feature comparable the same driver was used in both cases. These experiments were made over various soils, over different lengths of road, with varying loads, and at different speeds. The results of the trials are summed up in the following table:—

Experiments in Snow.

	Iron Tyres.	Pneumatic Tyres.
	lbs.	lbs.
Carriage at a walk, empty	34·89	25·23
Carriage at a walk, load of 330 lbs. ..	39·22	27·96
Carriage at a trot, load of 330 lbs. ..	65·12	33·59
Carriage at a trot, load of 660 lbs. ..	68·57	39·51

Experiments in Mud.

Carriage at a walk, empty	35·20	23·10
Carriage at a walk, load of 330 lbs. ..	38·06	27·34
Carriage at a trot, load of 330 lbs. ..	43·01	28·53
Carriage at a trot, load of 660 lbs. ..	50·73	31·15

Mean of Trials upon Macadam; Dry, New, Dusty, and Well-paved with Grades varying from 1·2 to 5·8 per cent.

Carriage at a walk, empty	38·32	30·91
Carriage at a trot, empty	44·90	35·09
Carriage at a walk, load of 660 lbs. ..	45·65	35·51
Carriage at a trot, load of 660 lbs. ..	65·31	36·08

These figures show that under all the conditions given the use of the pneumatic tyre diminishes the tractive effort; and this economy is greater upon a bad than upon a good road, and it also increases with the speed and the load.

Some experiments were made to compare the relative effect of iron tyres and pneumatic tyres with varying air pressure and with plain rubber. The results were as follows:—

At a trot, load 660 lbs.	44·22	44·75	43·91	56·52

Vehicle.	Iron Tyres.	Pneumatic. Air Pressure. 6·6 lbs.	9·9 lbs.	Plain Rubber.
At a walk, empty ..	33·64	36·03	34·34	37·62
At a trot, empty ..	46·64	33·99	41·69	44·15
At a walk, load 660 lbs.	44·22	44·75	43·91	56·52
At a trot, load 660 lbs.	64·20	45·14	50·64	63·96
Average	47·17	39·97	42·65	50·31

From this table it would seem that the full rubber tyre, while better than iron at a trot, is not so good at a walk. But Mr. Michelin adds that if the surface is muddy, or covered with snow, so as to remove all elements of elasticity, the full rubber tyre gives better results than an iron tyre. But the full rubber is always inferior in this respect to the pneumatic tyre; and for the latter it would appear that the pressure of inflation should not exceed 6·6 lbs. The general mean of the experiments of Mr. Michelin in traction give the following relative values:—

Pneumatic tyres	100·0
Full rubber tyres	129·8
Iron tyres	132·7

THE AUTOMOBILE ENGINEERS' DISCUSSION CLUB.

A MEETING was held at the "Coach and Horses," Clapham Road, on July 6th, of a number of gentlemen interested in engineering and other applied sciences, to discuss the advisability of forming a local club or society for the discussion of matters of interest and interchange of ideas and experiences, especially in connection with motor-vehicle construction.

Among those present were Mr. R. Fullerton Bell, R.N., Mr. C. M. Linley, M.C.E.I., Mr. Trigwell, M.C.E.I., and Mr. Preston Davies.

At this meeting it was decided that the Club should be formed, and a future meeting was arranged for July 20th, when the rules will be decided upon and a committee appointed.

The Hon. Sec. (*pro tem.*) is Mr. Arthur Power, 31, Kenwyn Road, Clapham, who will be pleased to receive any applications for membership.

DOINGS OF PUBLIC COMPANIES.

Electrical Power Storage Company.

The report of the directors of the Electrical Power Storage Company (Limited) for the year ended May 31st last, presented at the general meeting held on 14th inst., states that the net profit for the year is £4,389, which, with a balance of £242 from last year, amounts to £4,631, out of which the directors recommend the payment of a dividend of 5 per cent. on the ordinary share capital, which will absorb £4,275, leaving £356 to be carried forward. Provision has been made for the maintenance of buildings, plant, tools, &c., at a cost of £2,610. A considerable portion of the area obtained during last year for the extension of the Millwall works has now been built upon, and the shops fitted with newest types of machinery. The increased facilities thus obtained have enabled the Company to keep pace with the growing demands for its manufactures. The Company is now producing nearly all standard British and Continental types of secondary batteries, provided with Planté formed or pasted plates. The directors are pleased to announce that during the year a Royal Warrant has been issued appointing the Company storage battery makers to Her Majesty the Queen. Owing to ill health, Mr. Frank King, who has been manager of the present Company since its formation, has tendered his resignation, and has been elected to a seat at the board.

British Hydraulic Jointing Company.

The following circular letter has been issued to the shareholders:—

"Dear Sir or Madam,—

"Mr. Hooley not being in a position to complete his contracts, the directors of the British Hydraulic Jointing Company have resolved not to adopt the contracts for the flotation of the Company, and to return in full the subscriptions of the shareholders. Formal notice convening a meeting of the shareholders of the British Hydraulic Jointing Company (Limited), for the purpose of winding up the Company, is sent herewith.

"The directors of the Hydraulic Joint Syndicate (Limited) have, however, arranged for the necessary working capital to carry on the business, and all the rights in connection with the patents in Great Britain and all foreign countries will be worked by the latter; and the directors of the British Company have been offered, and have unanimously accepted, seats at the board of the Syndicate, which will now consist of the following gentlemen:—The Right Hon. the Earl of Crawford (chairman), Lord Ashburton, Mr. W. Bromley Davenport, M.P., Lieut.-General Sir J. Bevan Edwards, M.P., Viscount Hood, Mr. Walter H. Maudslay, Sir James Pender, Bart., M.P. The capital of the Syndicate already issued is £400,000, and it is proposed to increase the capital by the addition of £50,000 ordinary shares, to rank *pari passu* with the shares already issued. £25,000 of these shares have already been taken up at par; the balance will be held in reserve for issue by the directors when required.

"Yours faithfully,

"Thos. W. Mills, *Secretary*.

"18, Regent Street, London, S.W.,

"*June 24th*, 1898."

An extraordinary general meeting of the British Hydraulic Jointing Company (Limited) was held on the 5th instant, in accordance with the above notice, at the Cannon Street Hotel, under the presidency of the Earl of Crawford, when a resolution for winding up the Company voluntarily was unanimously carried.

Hydraulic Joint Syndicate.

An extraordinary general meeting of the shareholders of the Hydraulic Joint Syndicate (Limited) was held on the 5th instant, at the Cannon Street Hotel, for the purpose of increasing the capital to £450,000 by the creation of 50,000 new ordinary shares of £1 each. The Earl of Crawford presided.

The Chairman said that the history of the British Hydraulic Jointing Company, which was floated by the Syndicate, commenced on January 4th of this year. The board sent out a circular informing the shareholders of the Syndicate that the engineer had made a certificate to the effect that the compressor was in a practically finished condition and ready to be placed before the public. The difficulties in bringing out the Company were very great indeed, and one of those difficulties was the magnitude of the capital demanded and the impossibility of showing on the prospectus an adequate return. The directors absolutely declined to pledge themselves to put down in figures what dividends were likely to be paid by the Company. Finally, the directors called a meeting of the shareholders of the Syndicate, when it was decided that the capital of the British Company should be reduced from £2,000,000 to £1,200,000. The vendor's profits were reduced, and the return to the Syndicate was also reduced to £800,000. An extra inducement was also given to the new Company by the addition of the French and Belgian patents. The new arrangement was carried out with the consent of Mr. Hooley, who was singularly liberal to the shareholders of the Syndicate, for he was to receive only £25,000 of any cash payments to the Syndicate for himself. Mr. Hooley was willing to accept an arrangement that his entire cash profits should come last. The Company was registered, and the prospectus and underwriting completed. The directors insisted that the working capital of £100,000 should be arranged for. The response to the prospectus by the public was remarkably small, something over £22,000 being applied for by the public, and out of that amount £2,200 or £2,300 was withdrawn between the date of issue and May 26th. After the deductions the applications for shares amounted to, roughly, £18,000, and the underwriter was called upon to provide £82,000 to make up the working capital. Having the full complement of working capital, the directors considered they were justified in going to allotment. The Chairman then went over the history of the Syndicate. He said that the Syndicate from the commencement had been in the curious position of having no working capital. The directors had to consider that if they returned the money of the new Company to the shareholders, then the Syndicate shareholders might have a very serious bone to pick because the new Company had the working capital, and, again, it would have been a severe blow to acknowledge the failure of bringing out the new Company, with the result that, in all probability, the Syndicate would have to go into liquidation, and a most valuable patent would have been lost to the proprietors. The only thing they had to look forward to was the *modus vivendi*, which was found by the means of an interview which the solicitor of the Company had with Mr. Hill, the underwriter. Mr. Hill naturally did not very much like having to put his hand into his pocket for £82,000 for a thing he knew nothing about. At a meeting held on June 10th, Mr. Hill handed the directors a letter, which stated that, in consideration of the Syndicate agreeing to take the necessary steps for increasing its ordinary share capital and allotting to him 25,000 of the new shares, he agreed to take the same on condition that the British Hydraulic Jointing Company (Limited) went into liquidation, with the object of returning in full the money found by himself and the other shareholders. He further agreed to pay the expenses of liquidation up to £300. The Chairman said that that placed them in this position: the money was returned to the shareholders of the British Company, and enabled the Syndicate—the mother Company—to have a certain amount of capital in order to prosecute legitimate work. The Chairman then moved the resolution for increasing the capital of the Company.

Mr. Walter H. Maudslay seconded the motion, which was carried unanimously.

The Earl of Crawford, Viscount Hood, and Lord Ashburton were re-elected directors of the Syndicate, and the following gentlemen were also elected on the board:—Mr. W. H. Maudslay; Lieut.-General Sir J. Bevan Edwards, M.P.; Sir James Pender, Bart., M.P.; and Mr. W. Bromley Davenport, M.P.

The Chairman stated that Lord Ashburton wished him to say that the directors did not desire to take fees until the Syndicate was in a paying condition.

Lu-Mi-Num Manufacturing Company.

The liquidators of the Lu-Mi-Num Manufacturing Company (Limited) last month called an extraordinary meeting of the shareholders at the offices in London, to consider a resolution formally approving of the reconstruction of the Company on a basis which provides that the contributors agree to surrender their shares to the aggregate number of 118,000, and accept in exchange 30,000 new ordinary and preference shares credited with 15*s*. paid.

The New Rossleigh Cycle and Motor Company (Limited).

MR. P. C. MARTIN, chairman, presided at the statutory meeting of the above Company, which was held in Edinburgh on June 27th. He congratulated the shareholders on the continued prosperity of the Company, indicating that the business had increased about 50 per cent. last year. He added that the Company was keeping the subject of motors and motor-cars close before it, and he was certain this would shortly develop into a huge business of a most profitable kind, and one that would be a very valuable adjunct to the cycle trade. Mr. T. M. Sleigh, one of the managing directors, said great success had attended the opening of new depôts in Glasgow and the West of Scotland. Mr. Sime, C.A., moved that stock be taken at October 15th, and a balance-sheet made up and submitted to the shareholders in November, which was seconded and unanimously agreed to. This concluded the business.

New Issue.

THE London Steam Omnibus Company (Limited), with a share capital of £420,000, in £10 shares, of which 2,000 are founders' shares, has been formed to put upon the streets of London and other large towns steam and other motor-buses, chars-à-banc, and cars. According to the prospectus, it is also proposed to run lines of steam buses on a daily service from London to other towns, and from town to town. This Company will have a license from the British Motor Company for the sole right (within a radius of 20 miles round the General Post Office, London) to work the De Dion and Bouton system of steam buses, and will also be entitled to use throughout this country and Ireland the systems of motor-bus as used by Panhard and Levassor and Daimler. An agreement has been entered into with the British Motor Company (Limited), the vendor, by which the vendor grants these licenses, receiving in consideration £210,000 in cash or fully-paid ordinary and founders' shares, the proportion being one founders' for every 20 ordinary shares. Subscribers of 20 shares will have the right of securing one founders' share at par. No dividend will be payable on the vendors' shares until the business has earned a net profit of more than 6 per cent. upon the capital subscribed and paid up. The vendors' shares are then entitled to dividends until they have received 6 per cent., when all the shares are entitled to rank equally for dividend. After the Company has paid a dividend of 6 per cent. upon its entire issued capital, the distinction between the two classes of shares will thereafter cease. The founders' shares take one-third of the remaining profits in each year after 8 per cent. has been paid upon the ordinary shares, and after making a due allowance for reserve.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

Cam Gear Syndicate (Limited).—Registered by W. T. Hick 2, Church Court, Clements' Lane, E.C. Capital £12,000, in £1 shares. Object, to enter into an agreement with D. E. Radclyffe, A. H. Smith, T. W. Kent, W. Bromley, W. H. D. Tyler, and T. H. North, and to manufacture, sell, and deal in cycles, motors, motor-cars, tools, engines, &c.

Egdell Cycle and Engineering Company (Limited).—Registered by E. E. Clark, 61, King William Street, E.C. Capital £2,500, in £1 shares. Object, to carry on the business of cycle, motor-car manufacturers, engineers, &c. Registered office, 59, Holborn Viaduct, E.C.

Humburto Patent Cycle and Engineering Company (Limited).—Capital £100. Objects, the acquiring of a cycle and motor-car making and engineering business at Nottingham, at present carried on by a private individual.

London Steam Omnibus Company (Limited).—Registered by Ashurst and Co., 17, Throgmorton Avenue, E.C. Capital £420,000, in £10 shares. Object, to adopt and carry into effect an agreement, expressed to be made between the British Motor Company (Limited) of the first part, and this Company of the other part, and to construct, maintain, and work omnibuses, vans, carriages, launches, steamboats, and other vehicles or means of conveyance, whether for use by land or water, and the like, appropriate for the carriage and transport of passengers and goods, whether propelled by animal traction or by steam, oil, electricity, or any other motive power, and to obtain any necessary licenses for the same, whether under the Hackney Carriage Act or otherwise; also as electricians, mechanical engineers, &c., &c.

Lu-Mi-Num Cycle Company (Limited).—Registered by Sugden and Harford, 10, Ironmonger Lane, E.C. Capital £50,000, in £1 shares (10,000 are preference). Object, to enter into an agreement between the Lu-mi-num Manufacturing Company (Limited) of the one part, and William E. Watson (for the Company) of the other part, to manufacture and deal in bicycles, autocars, and motors of every description, and the various parts thereof, and to carry on the business of mechanical engineers. Registered office, 75, Queen Victoria Street, E.C.

Reavell and Co. (Limited).—Registered by Nunn and Popham, 140, Leadenhall Street, E.C. Capital £50,000, in £10 shares (600 are deferred). Object, to acquire from the Scott Engine Syndicate (Limited), Norwich, certain patent rights in relation to the Scott high-speed constant thrust compound engine, to acquire Reavell's patent air compressor, to enter into agreements with (1) the Scott Engine Syndicate (Limited); (2) William Reavell and Co.; (3) Charles Gaskell; and (4) William Reavell, and to carry on the business of engine builders, mechanical engineers, &c. The first directors are William Reavell, Charles Gaskell, and William H. Scott.

Roland Elastic Wheel Syndicate (Limited).—Registered by E. E. Clark, 61, King William Street, E.C. Capital £12,000, in £1 shares. Object, to acquire certain patents, and to manufacture and deal in cycles, motors, &c. Registered office, 20, Bucklersbury, E.C.

H.R.H. THE PRINCE OF WALES AND AUTOMOBILISM.

THE Prince of Wales, on June 25th, had his first ride in an up-to-date petrol motor-car, and appears to have been well pleased with his experience. The ride was between Warwick and Compton Verney. The cars used were sent over from Coventry by the Daimler Motor Company. The Prince, accompanied by the Countess of Warwick, Lady Randolph Churchill, and the Duke of Marlborough, occupied the first car, a Rougemont wagonette, fitted with a 4 H.P. Daimler motor, and driven by Mr. J. S. Critchley. The second car contained the Earl of Warwick and General Sir Stanley Clarke, the Prince's equerry; this car was driven by Mr. Meyer. In the third car were the Hon. J. Churchill, the Hon. Richard Molyneux, and Mr. Ronald Moncrieff, with Mr. Drake as driver. A fourth car contained Mr. Altree of the Daimler Company. Outside the castle and at various points along the route, where people had gathered, His Royal Highness was loudly cheered. The run to Compton Verney took an hour and ten minutes. At Compton Verney the Prince and party were the guests of Mr. Orr Ewing at the fine mansion, which is the property of Lord Willoughby de Broke. The stay was a short one, just sufficient for refreshments, and to view the hounds which were drawn up on the lawn. The party returned by a different route to Tachbrook House, where they lunched with Mr. and Mrs. Low, before returning to Warwick. The Prince expressed their pleasure at the journey and the manner in which the hills were mounted; he particularly noticed and commended the absence of vibration. The other members of the party also expressed their delight with the journey and the smooth running of the cars. There was only one incidental stoppage on the way, and that but slight, when the Prince's car in mounting a very steep hill on the return journey was pulled up by the heavy state of the road. A little assistance from the onlookers, who were quite enthusiastic to have the honour of pushing the Prince's car, quickly overcame the difficulty, and the car proceeded merrily on its way. Previous to the trip to Compton Verney the Prince, accompanied by the Countess of Warwick, was driven round the grounds of Warwick Castle by Mr. Critchley in a special car, driven by a four-cylinder engine, and geared to its top speed, 26 miles an hour. The Prince was taken several times round the grounds, but owing to the many turns the speed could not be kept so great as under other circumstances, although at 26 miles the Prince was doubtless fully impressed with the possibilities of automobilism. The rapid travelling appeared to very much please His Royal Highness.

A PETROLEUM AUTOMOTOR FIRE-ENGINE.

Steam fire-engines as used up to the present time have not enabled firemen to compete with fires either effectually or rapidly, although the volume of the jet is infinitely more considerable than that of the hand fire-engines. Unfortunately, too, owing to the crude methods employed, the working of a steam-engine requires time—practically not less than 15 to 18 minutes—to obtain a full head of steam. Harnessing the horses, &c., also takes a considerable time, and one must reckon on half an hour at least between the time the alarm was given and the engine is ready to work—at least, this is the London experience.

With a petroleum automotor fire-engine (the first idea of which is said to be due to M. Leon Porteu, Lieutenant of the Rennes firemen) the numerous inconveniences of the steam engine drawn by horses are considerably minimised. M. Porteu's first patent is now some years old, but, thanks to his energy and perseverance, he has at length succeeded in constructing a petroleum automotor fire-engine which is likely to have a big future before it. All the details of the engine (which we illustrate) have been worked out by Messrs. Th. Cambier and Co., with the help of M. Leon Porteu.

This engine is composed of a frame in steel sections, mounted as usual on wheels, with this difference—that the front axle is a director, as with nearly all the automotor carriages. Behind the driver's seat is the motor, with four cylinders of Cambier and Co.'s make placed longitudinally. The main shaft drives, by means of mitre and bevel wheels, an intermediate shaft, on which is mounted gear, sprocket wheels, &c. This intermediate shaft also gears with the pump shaft. The water for cooling the motor cylinders is carried in a tank, and when the pumps are running a connection from the pump pressure chamber easily replenishes the former. The power developed by the motor is 30 B.H.P.; this projects a stream of water, the volume of which is about 400 to 500 gallons per minute under a pressure of 150 lbs. per square inch. For igniting the charges in the motor-cylinders, and also for giving a powerful light on the scene of operations, a small storage battery is carried which, when charged, suffices for an eight hours' expedition.

It is easy to see the great advantages of petroleum automotor fire-engines. If kept in perfect condition they can be set in motion in a few seconds after the alarm has been given. The starting occupying but a minute or so, the arrival on the scene of the fire can be effected 15 minutes sooner than the most rapid steam-engine. The run can be made at an average speed of 9 to 10 miles per hour. Immediately on arrival at the scene of the fire the vehicle is brought to a standstill, and the motor, which has not been stopped, sets the pump in motion, and, as soon as the hoses are unrolled and connected with the water pipes, the pumping engine can give out its greatest duty. This sort of engine, as tested by trials, can attack a fire 20 minutes quicker than an ordinary steam-engine well kept and well worked. This difference in time can in almost every case prevent an extension of the fire, and, thanks to the Porteu system, considerable disasters can be avoided in future. We commend this notice to the London County Council Fire Brigade as it is simply not true to state publicly that there are no efficient automotor fire-engines, and make this statement an excuse for the *laissez faire* policy of the Council in the matter of fire prevention.

This fire-engine will be brought over by Messrs. Cambier and Co.'s sole agent for Great Britain, viz., Mr. Frentzel, and will be on view in about three weeks' time.

A French Petroleum Motor Fire-Engine.

Automobilism in France.—The past few weeks have been crowded with events connected with automobilism. There have been the Brussels-Spa Competition, the Paris-Amsterdam Race, the Exhibition of Vehicles in Paris, the Paris Cab Competition, to mention the principal events. We have found it impossible to deal with so many items, owing to the importance of other matters, but as, with the exception of the Paris Cab Competition, the events referred to do not possess any great technical interest, we in our present issue have not attempted to discuss them.

SELF-PROPELLED TRAFFIC ASSOCIATION

(INCORPORATED).

LIVERPOOL AND DISTRICT CENTRE.

Second Session, 1897-98.

THE annual general, tenth, and last ordinary meeting of the session was held in the board room of the Incorporated Chamber of Commerce, Exchange Buildings, Liverpool, on Tuesday afternoon, July 12th, 1898, Mr. Alfred L. Jones, J.P., Vice-President, in the chair, when the following annual report of the Council was presented :—

At the close of the second session the Council beg to present the following report.

The additions to the roll have been 30. Ten names have been removed from the register, of which four are due to removals beyond the limits of the area embraced by the Centre, four are due to resignation, and two to death. At the present date the number of members is 64, compared with 44 at the close of the first session.

Messrs. H. Percy Boulnois and Everard R. Calthrop, who removed to London during the session, have been elected members of the General Council. The Council desire to place on record their appreciation of the valuable services rendered by these two gentlemen during their term of office on the Council of the Liverpool Centre.

Jurisdiction.—The Liverpool and District Centre has been defined as including the counties of Lancashire and Cheshire with North Wales. Members of the Association who are resident outside the boundaries of the Centre may be attached thereto by permission of the General Council. The contemplated amalgamation or fusion between the Association and the Automobile Club of Great Britain will in no way prejudice the Liverpool Centre.

Finances.—The arrangement referred to in the report of the first session, whereby it was proposed that the Centre should control its own finances and contribute a fixed percentage of its income to the Head Centre, has been duly completed. It has been agreed that this Centre shall pay to London 10 per cent. of the amount of the subscriptions received from the members on the local register. A statement of accounts to June 30th, 1898, has been duly audited by the London Secretary, Mr. Andrew W. Barr, P.S.A.A.

Arrangements with Foreign Clubs.—Members have, through the courtesy of the respective committees, the advantages of honorary visiting membership of the Automobile Clubs of France and Belgium. Official cards may be obtained from Mr. Andrew W. Barr, London.

Library.—A nucleus has been formed, and the Council hope that as the membership increases it will be possible to devote an adequate sum to the purchase of works connected with the history and present position of self-propelled traffic.

Models and Specimens.—The Centre is indebted to Messrs. Ibbotson Brothers and Co. (Limited) and Messrs. Samuel Fox and Co. (Limited), Sheffield, for the collection of springs used to illustrate Mr. Joseph Bedford's paper on "Steel Springs"; also to the Chloride Electrical Storage Syndicate, the Electrical Power Storage Company (Limited), the Elieson Lamina Accumulator Company (Limited), and the Lithanode Electrical Storage Company for the collection of accumulator plates used to illustrate the paper by Mr. J. T. Niblett.

The Session and Meetings.—A deputation of the Council represented the Centre at "Les Poids Lourds," which were held under the auspices of the Automobile Club de France from August 5th to 12th, 1897, in the neighbourhood of Versailles. These trials were the first held for heavy loads, the minimum being one ton of goods. A report was drawn up, in which the proceedings during the competition, the points of the various vehicles and of the Serpollet tramway system were described. This was published on September 16th, 1897, and was widely circulated. The session was opened on November 26th, 1897, by Mr. W. Worby Beaumont, M. Inst. C.E., M. Inst. Mech. E., M. Inst. E.E., who was entertained at luncheon at the Exchange Station Hotel by Mr. Alfred L. Jones, J.P. (Vice-President), who also invited the members of the Council and a number of leading citizens to meet him. In the evening Mr. Worby Beaumont delivered an inaugural address entitled "Self-Propelled Vehicles, 1896-97," in the course of which the progress made during the previous 12 months was reviewed. It was remarked, in opening, that the attack which had been made on the problem of the mechanical propulsion of common road-vehicles had materially lessened its problematic character, and that the benefits to be derived from the changes to be wrought in our road and street transport methods were being gradually appreciated. The vehicles that took part in the trials at Versailles, also a number of experimental and other English vehicles, were described at length, various illustrations being projected upon the screen. It was considered that the motor goods-van for loads up to 20 cwt. was a workable and economical machine, and that improvements would soon enable heavier loads to be carried. Finally, it was pointed out that heavy loads per axle were to be avoided, more particularly in view of traffic upon macadam roads in wet weather, and the conclusion was arrived at that loads considerably less than 10 tons per vehicle were desirable, or that a form of vehicle with six or eight wheels, all dirigible, must be designed. The President, the Right Hon. the Earl of Derby, K.G., was unable to be present on account of the sad death of Lady Lathom, and his place was taken by Mr. Alfred Holt, M. Inst. C.E., Vice-President. Subsequent meetings were held, at which papers upon the several subjects enumerated in the following summary were read and discussed :—

December 14th, 1897.—Mr. W. Hugh Woodcock, M. Inst. C.E.: "Roller Bearings."

January 25th, 1898.—Mr. Geo. Herbert Little (technical editor of THE AUTOMOTOR): "Some Points in the Design of Automobile Vehicles intended for Heavy Traffic."

February 22nd, 1898.—Messrs. D. H. Simpson and W. L. Bodman: "An Account of our Trials and Experiments, with the Conclusions drawn therefrom."

March 1st, 1898.—Discussion upon Messrs. Simpson and Bodman's paper.

March 15th, 1898.—Mr. Joseph Bedford: "Steel Springs."

March 29th, 1898.—Mr. J. T. Niblett, M. Inst. E.E.: "Recent Improvements in Accumulators and their Application to Traction on Common Roads."

April 14th, 1898.—Mr. E. Shrapnell Smith (Hon. Local Secretary): "The Arrangements for the May Trials."

July 5th, 1898.—Nomination of Council and Officers.

July 12th, 1898.—Annual General Meeting.

The paper announced to be read by Mr. Henry S. Fearon, Assoc. M. Inst. C.E., on "Leather Tyres," was unavoidably postponed to next session.

The average attendance during the session equalled 38 at each meeting.

Proceedings.—The proceedings of the Centre have been fully reported in the semi-official journal of the Association (THE AUTOMOTOR). The engineering Press generally have summarised most of the papers.

Trials of Motor-vehicles for Heavy Traffic.—The session was brought to a successful termination by the competition held from May 24th to 27th, 1898. The chief object of the trials was "to arrive at a type of heavy motor-wagon suitable for trade requirements in Liverpool and neighbourhood, which shall be capable of economically taking the place of horse haulage and of competing with the existing railway rates, in the transport of heavy loads of goods over considerable distances." Awards amounting to £225 were offered to be made at the discretion of the judges. The conditions of the trials were published on November 16th, 1897, thus giving only six months for intending competitors to build. It must, however, be borne in mind that a number of firms had already been engaged upon experimental vehicles for upwards of 12 months, so that the objection of short notice is not so important as might appear. Out of ten entries by six firms only four vehicles were presented for trial. These carried loads of from 2 to 5 tons, and covered the prescribed courses of 35 miles each, with results of a very encouraging character. The competing firms were:—

The Liquid Fuel Engineering Company (Limited), East Cowes, Isle of Wight.

The Steam Carriage and Wagon Company (Limited), Chiswick.

The Lancashire Steam Motor Company, Leyland.

The trials were attended by a large number of engineers, merchants, shipowners, and others interested, from all parts of the country. The Automobile Clubs of France and Belgium, the Secretary of State for War and the Postmaster-General, and the Corporations of Hull, Liverpool, Manchester, and Wolverhampton, sent official delegates. Representatives of *The Times* and *Daily Telegraph*, of all the technical journals, and of the local press, followed the competition. The report of the judges is now in course of preparation. During the continuance of the trials entertainments were provided for our foreign and other visitors.

A dinner took place at the Adelphi Hotel on the evening of Thursday, May 26th, 1898, when about 140 members and friends were present, including Sir David Salomons, Bart, who presided, the Right Hon. the Lord Mayor of Liverpool (Alderman John Houlding); Mr. Alfred L. Jones and Mr. Alfred Holt, Vice-Presidents of the Liverpool Centre; Mr. R. W. Wallace, Q.C., Chairman of the Automobile Club of Great Britain; M. Pierre Giffard, Membre du Comité de l'Automobile Club de France; M. François Thy (Bourgomestre de Pecq); F. C. Danson, President Liverpool Chamber of Commerce; W. A. Darbishire, Penyhryn, Carnarvon; Charles H. Darbishire; Richard M. Greaves; John I. Thornycroft, Chiswick Mall, W.; John E. Thornycroft; Herbert Niblett; Boverton Redwood, Church End, Finchley, N.; J. E. Thornton, Altrincham, Cheshire; J. P. Lea; Alfred J. Ling, Bollington, near Macclesfield; H. A. The best thanks of the Association are due to the following gentlemen, firms, and Corporations, for their valued assistance:—

The Members of the Trials Sub-Committee who drew up the conditions and rules of the competition:—Messrs. Alfred Holt, Jno. A. Brodie, Everard R. Calthrop, S. B. Cottrell, Henry H. West, and E. Shrapnell Smith (Hon. Sec.).

Judges: Sir David Salomons, Bart.; Prof. Boverton Redwood, F.R.S.E., F.I.C.; Professor H. S. Hele-Shaw, LL.D., M. Inst. C.E., M. Inst. Mech. E.; Mr. S. B. Cottrell, M. Inst. C.E., M. Inst. Mech. E.; Mr. Henry H. West, M. Inst. C.E., M. Inst. N.A., M. Inst. Mech. E.

Observers: Messrs. Francis E. Baron, Henry Fowler, W. G. Hay, and J. Walwyn White (senior observers in charge); Messrs. Wm. Bayliss, R. Edgar Boulton, C. A. Charlewood, A. R. Ellison, Humphrey N. Giles, L. H. Huddart, J. C. W. Humfrey, Norman C. Lange, A. M. Lodge, J. H. Lowery, H. Owens, E. A. Rosenheim, J. Reginald Taylor, and Charles Stewart.

The Mersey Docks and Harbour Board, for the use of their Prince's Dock Yard and their tender, the "Vigilant."

Mr. John Thomas Wood, M. Inst. C.E., for preparation of plans and profiles of the routes.

Messrs. Hooper and Simmons, for storage accommodation for the light carriages.

Messrs. Ismay, Imrie, and Co., for permission to see the R.M.S. "Majestic."

Messrs. Hy. Pooley and Sons (Limited), Liverpool, for loan of weighing machines.

Mr. J. Sydney Critchley, M. Inst. Mech. E. (Works Manager, the Daimler Motor Company), for courteous and unremitting attention in connection with the service of light carriages.

The thanks of the Council have been duly communicated to the respective parties.

FURTHER COMPETITION, SEPTEMBER, 1899.

The results of the recent trials being regarded as highly satisfactory for a beginning, it has been decided to organise another series of trials of motor-vehicles for heavy traffic to take place in the month of September of next year.

The routes selected are the two main roads between Liverpool and Manchester. The conditions will be issued shortly.

LOCOMOTIVES ON HIGHWAYS ACT, 1896.

The following resolution was unanimously adopted by the Council at a meeting held shortly after the recent trials:—

Resolved—"That the Liverpool Council of the Association is of opinion that the existing maximum of 3 tons tare imposed by the Locomotives on Highways Act, 1896, very seriously hampers and in many cases prohibits the construction of vehicles of the types required for the heavy traffic of this district, and a recommendation is hereby made to the General Council that the whole forces of the Association shall be immediately directed towards the obtaining of an amendment to the Act whereby (*a*) *all restrictions upon weight shall be removed;* or, if it be deemed inexpedient to remove all limitations, (*b*) a limit upon the total moving weight, or upon the weight per axle, shall be substituted for the present limit of 3 tons tare; or, if it be considered imperative to retain a limit upon the tare (*c*) the tare permissible shall be increased to at least 4 tons."

It is hoped that joint action will be taken shortly to give effect to one of these clauses.

OBITUARY.

The Council have to regret the deaths of two members, viz., Mr. George Kendall, Messrs. C. S. Wilson and Co., Liverpool, and Mr. Edmund Rothwell, Assoc. M. Inst. C. E., Engineer and Managing Director of the Bury, Rochdale, and Oldham Tramways Company (Limited), Rochdale.

The CHAIRMAN (Mr. Alfred L. Jones, J.P.), said: Gentlemen,—In submitting for your approval the annual report of the Council, I am sorry that our president, Lord Derby, is not with us to-day, but we are glad to know he takes the very keenest interest in the operations of this Society, and is a firm believer in the possibilities which we endeavour to promote. I am pleased to see that our trials, as the report will show, have been far more successful than the first efforts of railway making in this country. I believe that time is the only thing required to enable us to have self-propelled vehicles for moderately heavy weights, say, up to 10 tons, to travel at one-fourth the present cost of railway rates. It will be evident to anyone that any machine of the kind, which can be brought to work, will have such a saving effect that the railway companies will have no chance, because the cost of unloading from cart to railway wagon, and from railway wagon to cart again, is so great that a direct wagon taking goods from the ships' side will be able to do it, as I have said, at one-fourth the cost of the present railway rates. There can be no question that the railway companies, by the attitude they have taken up, absolutely promoted the Manchester Ship Canal. This question of cheap carriage is of vital interest to Liverpool, and of far more direct importance than the most burning political question now discussed by the country. Our members of Parliament should be instructed by their constituents to protect us from the railway companies, and in the meantime we can proceed with better and cheaper methods of traction created by the conditions imposed upon us by the railways. One matter which is a great injustice to Liverpool latterly has been the reduction given to London and Southampton of 25 per cent. off the rate previously charged, whereas no reduction has been given to Liverpool. As I have frequently said, if Liverpool had cheap railway rates from Lancashire, she would have a far greater proportion of the West Indian, the Cape, and other trades. It is outrageous to suppose that Liverpool should be placed at the disadvantage of goods being taken away to the south coast, 200 miles by land, when Lancashire has a shipping port close at hand like Liverpool. We are now preparing for the 1899 trials, and in those trials we hope to offer a much larger premium; and here I would like to take the opportunity of thanking the subscribers for the very liberal support that this Association has received. The amount subscribed for our trials of 1898 amounted to £613, and next year we hope to double that amount, thus making the 1899 motor-car trials of Liverpool more or less a national question. We hope also that we shall have a commercial solution of this problem to submit, and that is, that we shall propose to combine with these trials the offer of a syndicate to provide cargo for distances up to, say, 30 miles, so that makers of vehicles may see there is real sound business in the scheme. I have no doubt in 1899 we shall receive from the Liverpool Corporation and from the Dock Board that support which they ought to give. Cheap carriage to Liverpool trade means life. Where would Liverpool be without her docks and shipping? Our authorities should keep a watchful eye on these facts. As regards the use of the roads, practically the whole of the traffic is already conveyed by the roads along the docks. Now, if the traffic can be carried along these roads, it will be just as easy to carry it to any place within 30 miles of Liverpool. Another matter which is very important, and which will be an element of great advantage in the future is, that the time saved by the self-propelled wagon will be greatly in its favour. For instance, a wagon can leave Liverpool at night and be at the factory door in Manchester at six o'clock the next morning. These are days of rapid progress, and I think it is much to the credit of Liverpool that she has taken a prominent place in the efforts to develop cheap carrying.

Mr. ANTHONY G. LYSTER said: I have very great pleasure in seconding the proposal of the adoption and circulation of the report, and think the local Association is very greatly to be congratulated upon having achieved so much within so short a period after its formation. The view which it has taken of automobilism has been that of applying it to the direct needs of the vast commerce with which our port deals, and in regarding it in this way the Association has probably taken the most practical step towards its useful spread for general commercial purposes, as there are few of the world's trades which are not more or less in touch with the great centre of Liverpool, and do not look to it for a lead in some form or another. As our Vice-President has said, the whole gist of the transactions of the Association during its short term of life lies in the recent trials of automotor wagons for dealing with heavy traffic. Other important duties it has undoubtedly performed, which must all bear fruit in directing public attention to this modern development and spreading information with regard to it; but the all-important function which it has performed has been to attempt to demonstrate, by practical experiment, the possibilities of the transport of goods from Liverpool to the manufacturing districts by more economical and simple means than at present exist. Mr. Jones has dealt with the commercial aspects of that experiment, and inasmuch as its pressing need has been a matter of universal talk in business circles for many years past, I need not, I think, dwell any longer upon that view of the question. I should like, however, to say a few words from a more technical point of view, and try and set before you how, in my judgment, the chance at present stands for the introduction of the automotor wagon for this purpose. In doing this I do not wish in any way to attempt to forestall the report of the judges on the trials—which, from the information at their disposal and the very careful consideration which they will no doubt bring to bear upon them, will deal much more technically with the matter than I am able—but merely to give you my general impressions after reading the account of the trials as given by the Press. In the first place, it occurs to me that it has been demonstrated beyond all possibilities of doubt that an automotor wagon can take a reasonably heavy load for a distance of 35 miles along such main roads as exist in our neighbourhood, and up such inclines of varying grades as present themselves on these roads at speeds which meet all practical requirements. Secondly, that they can be manœuvred with quite as great if not greater facility than, say, a lorry with a pair of horses. Thirdly, there is the all-important question of the cost at which this can be done. At the present time, to take a ton of goods from a dock shed in Liverpool, transfer it to the railway depôt, there to place it upon a railway wagon, to transfer it by rail to Manchester, to unload it there, place it upon a lorry, and convey it to a warehouse, will on the average probably cost about 10s. According to the results of the recent trials, and allowing ample margin on many accounts which must still remain matters of estimate, a ton of goods can be transferred from the shed in Liverpool to the warehouse in Manchester for from 3s. to 4s., say for two-fifths of the cost of the existing railway and cartage rates. This seems to me a most important result, and inasmuch as the time of transit would probably be less than half of what is on the average taken by the railway, it appears to me proved beyond all possibility of doubt that the two most important elements of time and money are both enormously economised by the adoption of the automotor wagon system. Perhaps the only other question in connection with this means of traffic which requires consideration is that of the roads. As regards this I am not prepared to say at the moment what is the best provision to be made for meeting the extra wear and tear, and who should be at the expense of making that provision, but I feel sure that both of these questions are capable of simple solution, and that even should the expense be borne directly by the traffic, it would only be a fraction of the cost of transport. I pass over the question of minor breakdowns, which are inseparable from first essays of this character, as they are all to be traced to a want of practical experience in details, and can all, in my judgment, be simply and readily rectified. These results, which I believe are correct, and which anybody can practically verify for himself by careful consideration of the published accounts of the trials, seem to me of enormous importance to the trade of this port, and the more so when we consider that this is practically the first experiment which has been made in this direction, and that without doubt as time goes on, and as experience is gained, and the present restrictions in regard to load to be carried removed, very great economies will be effected. I think, in conclusion, that these few remarks, coupled with those which have preceeded them, will form ample justification for the recommendation which the vice-president and myself have the honour to bring before you, and I am sure that not only will the Association be ready to accept that recommendation, but they will also be prepared to congratulate themselves and the Council upon having secured such important results in so short a space of time.

Mr. A. HOLT said he wished to define his position in the Society. The object of the Association was the scientific investigation of self-propelled vehicular and locomotive road traffic, and for that purpose he still remained a member, and would give such services as he could with that object.

The resolution, "That the report of the Council of the Liverpool Centre of this Association be adopted and circulated," was then put and carried unanimously.

The next resolution was: "That the best thanks of the Liverpool Centre of the Association be given to the retiring Council and officers for their services during the past session," moved by Mr. F. C. DANSON (President Liverpool Chamber of Commerce), and seconded by Mr. J. WALWYN WHITE, who said that when they thought of the difficulties which surrounded the work of these gentlemen—to arrange for trials, &c., that were without precedent—they would realise the arduous nature of the work to be done. He wished to call special attention to the great amount of work done by one alone—their able hon. secretary.

The CHAIRMAN said that the work had been a pleasure to them. Personally he felt that there were very great possibilities for the motor in Liverpool. With regard to Mr. Holt, of course they did not want his position misunderstood—nor did they want their position misunderstood. The Society was formed to investigate and to try and find out the possibilities of some new motor power which would be cheaper than the present means of carriage. They thought they had so far succeeded fairly well. The trials were very creditable, and showed clearly that there were great possibilities in the future. Having succeeded so far, they were greatly encouraged to go on, and they thought the 1899 trials would show a development that would surprise a great many people.

The next resolution—"That the best thanks of the Liverpool Centre of the Association be given to the Rules Sub-Committee, the Judges, the Observers, the Mersey Docks and Harbour Board, Mr. John Thos. Wood, and others for their valued assistance in connection with the trials of motor heavy traffic"—was moved by Mr. GEO. H. COX, and seconded by Mr. A. BROMLEY HOLMES (City Electrical Engineer), and carried unanimously.

Messrs. Lloyd and Walker, Chartered Accountants, 5, Castle Street, Liverpool, were unanimously elected as Hon Auditors.

A vote of thanks to the Chairman closed the proceedings.

The Right Hon. the Earl of Derby, K.G., has been again elected as President, Messrs. Alfred Holt, Alfred Jones, and John A. Brodie as Vice-Presidents, Mr. Lawrence Jones as Hon. Solicitor, and Mr. E. Shrapnell Smith as Hon. Secretary, and when the ballot papers for the election of Council to hold office till May, 1900, were unsealed the following were declared duly elected:—Messrs. M. C. Bannister, S. B. Cottrell, Geo. H. Cox, Prof. H. S. Hele-Shaw, Mr. A. Bromley Holmes, the Right Hon. John Houlding (Lord Mayor), Messrs. Anthony G. Lyster, Arthur Musker, Coard S. Pain, Henry H. West, John Wilson, and John Thos. Wood.

CERTAIN questions having arisen as to the method of balloting for the election of members to the Council of the Liverpool Centre, we are requested by Mr. E. Shrapnell Smith, Hon. Local Sec., to give the following outline of the arrangements, in order to make it quite clear that the secrecy of the ballot was in no way sacrificed:—The marked lists were enclosed by the members in envelopes, and the envelopes were signed, as a guarantee that the ballot sheets were sent in by duly qualified members. These envelopes were opened at the Annual General Meeting, and, after the sheets had been taken out by the scrutineers, thrown indiscriminately into the waste-paper basket. The votes were then counted quite independently of any signatures.

THE SELF-PROPELLED TRAFFIC ASSOCIATION AND THE AUTOMOBILE CLUB OF GREAT BRITAIN.

A SPECIAL general meeting of the members of the Self-Propelled Traffic Association was held on the 4th inst. at Cannon Street Hotel, to consider a proposal for amalgamation or fusion with the Automobile Club of Great Britain. Amongst those present were Sir David Salomons, Bart., Professor Boverton Redwood, F.I.C., F.R.S.E., Messrs. W. Worby Beaumont, J. J. Vickers, Walter Hancock, Henry A. Naismith, Stanley Spooner, Julius Harvey, Andrew W. Barr (Secretary), &c. Sir David Salomons, who presided, explained that the new organisation would not merely be a club, but what was called in France a Society of Encouragement. If the proposed fusion were agreed to, the members of this Association would be asked to fill up a form of application for membership of the Automobile Club. These applications would be submitted to a joint committee of both bodies, and he did not suppose that many, if any, of them would be rejected. The amalgamated body would have a club-house in London for the use of its town and country members, and all the benefits this Association enjoyed from its official connection with the French and Belgian clubs would be granted to the Automobile Club. He concluded by moving a resolution authorising the council to take the necessary steps to carry the proposed amalgamation into effect. Mr. Boverton Redwood, in seconding the resolution, expressed satisfaction that the friction which had existed between the two bodies had at last been removed, and said he considered that the amalgamation would be of mutual advantage. The resolution was agreed to unanimously.

AN extraordinary general meeting of members of the Automobile Club of Great Britain was held on Monday, July 11th, at the premises of the Club, 4, Whitehall Court, London, S.W., for the purpose of passing a resolution for the amalgamation of the Self-Propelled Traffic Association with the Automobile Club, the official title of the Club then to be "The Automobile Club of Great Britain and Ireland, with which is incorporated the Self-Propelled Traffic Association."

Roger W. Wallace, Esq., Q.C. (Chairman), presided, and amongst those present were the Hon. Evelyn Ellis (Vice-Chairman), Messrs.

Frederick R. Simms (Vice-Chairman), Frank Butler (Hon. Treasurer), C. Harrington Moore (Hon. Secretary), the Right Hon. the Earl of Galloway, K.T., Capt. the Hon. Cecil Duncombe, J.P., Messrs. W. Worby Beaumont, E. H. G. Brewster, Capt. A. B. Cunningham, Messrs. Robert Gray, H. E. Sherwin Holt, John Henry Knight, Col John W. Lee, Messrs. Patrick J. McManus, Richard Muirhead, Arthur Paget, Boverton Redwood, Arthur J. Walter, Bertram Blount, Harrington Edwards, Louis D'Egville, Berger Graham, E. M. C. Instone, Julius Harvey, Shaw Kennedy, E. Ledger, E. Lefehure, J. McManus, Frank Purchase, Lyons Sampson, Stanley Spooner, F. W. Wolf, C. Johnson (Secretary), &c. The object of the amalgamation and the negotiations leading up to the present resolution were briefly explained by the chairman, and after a short discussion the proposition was unanimously agre d to.

THE "RICHARD" MOTOR-VEHICLE.

The accompanying illustration shows the latest type of "Richard" vehicle which is being introduced by the Southern Motor-Car and Cycle Company, of Brixton Road, London, S.W. As will be seen, the vehicle is elegant and graceful in appearance and eminently suitable for use by professional men such as doctors. The mechanism is of the Benz type, but much improved in many details, one of which is the handle for starting the engine at the rear of the carriage, thus dispensing with the crude and rather dirty method of starting by turning the fly-wheel. The lower framework is of iron hung on springs, the wheels being of the cycle kind and fitted with pneumatic tyres. There is also a convenient attachment for preventing the chains, in the event of the latter stretching, from slipping off. All the various changes in speed, starting, stopping, &c., are effected by one handle in place of the usual two. The regulation brakes are fitted and, with the steering gear, are controlled by levers close to the driver. The vehicle is characterised by very high class workmanship and careful finish.

At Last!—The Metropolitan Railway Company have at length made a trial of liquid fuel for locomotives, having fitted a locomotive specially for the purpose on the system adopted on the Great Eastern Railway. The experiment was in every way a success, the smell of the oil not being noticeable. The first engine fitted with this plant was put in regular service on the 4th inst. There is no doubt that the passengers on the Underground Railway will speedily notice the absence of the suffocating fumes which they have experienced since the compulsory use of other than steam coal, which has been unavoidable since the Welsh miners have been on strike. The oil used is ordinary burning oil. This use of liquid fuel might have been tried at least 10 years ago, but our railway directors are too hopelessly wedded to obsolete methods.

SOME AMERICAN ELECTRIC MOTOR-VEHICLES.

Notwithstanding the generally bad state of roads and streets in the United States and Canada (we leave out Mexico, because roads in that country are merely mule-tracks sprinkled with boulders of the glacial epoch), electric traction makes commendable headway, and there are probably more types of motor-vehicles of all kinds employed by business houses in the United States than is the case in this country.

Fig. 1.

Owing to the almost universal use of electricity as a source of light and power in nearly every small town, and the consequent facilities for recharging electric traction, whether for railroads or street vehicles, is superseding every other system. For street vehicles the objection is, of course, the weight of the batteries, and

Fig. 2.

this is accentuated in most towns and cities by the bad condition of the streets. This objection is, however, more than counterbalanced by the cheapness of and the facility for obtaining current.

In the accompanying illustrations we show two typical American vehicles, designed and built by the Fischer Equipment Company, of Chicago. Fig. 1 is a light goods van. This is made in two sizes, the smaller having two 2 H.P. motors, and the other two 3 H.P. motors. In its general appearance this vehicle is light and elegant; there is a pleasing absence of obtrusive mechanism. The batteries

2 K 3

are carried in the bottom of the body, below the floor. The controlling switch and its accessories are in the boot, while the steering bar and reversing lever are placed conveniently to the driver's hand. The total weight of the vehicle (light) is 2,600 lbs. Fig. 2 is an electricab. The design of this vehicle will hardly, we think, commend itself in the matter of elegance. A hansom cab drawn by a horse is a graceful combination, but placed in front of and attached to another body and without the horse, as in this design, it produces an incongruous effect. This vehicle has two 3 H.P. motors. The batteries are arranged in eight trays, and are inserted in the cab from the rear end, making their own connections automatically as they are placed into position In the rear of the cab is a framework, which, when closed, forms a panel effect, and when laid down is held in position by two heavy straps, making a platform on which trunks and baggage may be carried, thus making the vehicle, at any rate from a utilitarian point of view, complete. The rear wheels are 38 inches diameter, and the fore wheels 34 inches diameter. The speeds are 3, 6, and 12 miles per hour.

The following are the leading particulars of these vehicles, for which we are obliged to our contemporary the *Carriage Monthly* :—

—	Delivery Van.	Cab.
Weight of vehicle only	650 lbs.	950 lbs.
„ batteries	800 „	1,000 „
„ two motors	180 „	230 „
Complete weight of vehicle	2,600 „	2,600 „
Load capacity	700 „	1,100 „
Total load propelled	3,230 „	3,280 „
Normal H.P. of each motor	1 ·16	1 ·67
Maximum H.P. of each motor	2 ·32	3 ·34
Speed of motor, R. P. M.	1,000	1,000
No. of motor	V 2	V 3
Weight of battery cells	1,007 lbs.	1,009 lbs.
Number of battery cells	40	40
Maximum speed of vehicle, miles per hour	12	12
Time of running .. .. (hours)	3 ·5	3
Average mileage capacity	36	30
Diameter of rear wheel	36 ins.	33 ins.
„ front wheel..	32 „	34 „
„ wheel gear	19¼ „	21 „
„ motor gear	2¼ „	3 „
„ hard rubber tyre	1¼ „	1¾ „
„ pneumatic tyre .. .	3 „	3½ „
Size of axle	1¼ „	1¾ „
Width of batteries in vehicle	27 „	27 „
Length „ „	40 „	52 „
Height „ „	11 „	11 „

HORSE AND MOTOR-VEHICLE ACCIDENTS.

Frightened Horses.—A shocking fatal carriage accident happened at Rugby on Friday, the 1st inst. Mr. Rose, of Rugby, a well-known horse dealer, was driving a pair of horses in a phaeton on Hillmorton Road, Rugby, when, being frightened, they dashed into the town. The vehicle overturned and he was pitched through a plate glass window and sustained such shocking injuries and cuts to the head that he died shortly afterwards. A little girl named Gamble, aged 10 years, a labourer's daughter, who was on the pavement, was killed instantly by one of the horses falling upon her, and her sister narrowly escaped. The groom, who was riding with Mr. Rose, also received serious injuries and was taken to the hospital.

Accident to an Actress.—Whilst driving through Grosvenor Square, on the 1st inst., Mrs. Pinero, wife of the well-known play-writer, met with a severe accident. She was driving a high-stepping horse, which stumbled, throwing her head first on to the horse's back and cutting her face on a sharp piece of harness. The horse was stopped by an onlooker and Mrs. Pinero was conveyed home in a cab.

THE AUTOMOBILISTS' SPEED TABLE.

COMPUTED BY G. H. LITTLE. (*Copyright.*)

1 statute mile = 1,760 yards.

Miles per hour.	Yards per minute.	Yards per second.	Time in seconds for 100 yards.

A GAS MOTOR BATH-CHAIR.

AN interesting trial with a coal-gas driven motor bath-chair recently took place in Birmingham, the inventor being Mr. W. H. Dunkley, of Birmingham, and the trial being held in the presence of a number of interested spectators. In shape the vehicle somewhat resembles a bath-chair, affording seating accommodation for one person. The extent and capacity of the car is, however, a matter which is regulated merely by the particular purpose for which any vehicle may be required. The body of the vehicle carries apparatus for compressing ordinary coal gas into a steel cylinder, and from this storage a regulated supply is admitted to the engine, which by means of a gearing drives the car. It is claimed that 30 cubic feet of coal gas will afford 1 H.P. for an hour, so that the cost of propulsion with gas at about 2*s* 6*d*. 1,000 cubic feet is not extraordinarily high. The car worked very well, the smell of exhausted gas and the vibration being apparently slight.

Motor-Car Exhibition.—We would again remind our readers of the Engineering, Machinery, and Motor-Car Exhibition, which will be held at the Agricultural Hall, Islington, from Monday, August 22nd, to Saturday, September 3rd, of this year. The Exhibition, as before, will be under the management of Mr. Charles Cordingley, and those wishing to book spaces can obtain plans, specifications, &c., from Messrs. Cordingley and Co., 39 and 40, Shoe Lane, London, E.C.

The Motor-Vehicle Industry.—As showing the confidence that the leading manufacturers of motor-vehicles feel in the future of the new industry, we may mention that both Messrs. Thornycroft (the Steam Carriage and Wagon Company), of Chiswick, and the "Lifu" Company, of Cowes, are selecting sites in the Midlands for the erection of large manufacturing works. Both firms at present have their hands full of orders, and find their present premises too small and not well adapted for motor-vehicle building.

THE MANSFIELD STEAM MOTOR-VEHICLE SERVICE.

As stated by us in a recent issue, a Company has been formed at Mansfield for the purpose of establishing a much-needed comunication with outlying towns by means of motor-vehicles. As the result of careful inquiries, and having regard to the great success that attended the use of the "Lifu" motor-vehicles in other districts, an order was placed with the Liquid Fuel Company, of London and Cowes, for a char-à-banc, an illustration of which accompanies be visited regularly. At present the car runs between Mansfield, Mansfield Woodhouse, Warsop, Sutton, Hucknall, Huthwaite, and Nottingham Road, Mansfield. On Wednesday afternoon, the 6th inst., the car, well laden, made an excursion round the Dukeries, returning in the evening without mishap of any kind.

In response to a request for an account of the performance of this vehicle, Mr. F. A. Robinson writes:—"From Friday, the 1st, to Saturday, the 9th inst., inclusive, we ran 434 miles, and carried 2,558 passengers. On Saturday last we ran the time table enclosed, 78 miles, and during the afternoon for 48 miles we had our trailing-car behind, which carries same number of passengers as char-à-banc (22), and only finished 50 minutes behind time, owing to the heavy traffic.

The Mansfield Char-à-banc "Pioneer" (Symon-House System).

this description. The new vehicle is appropriately named the Pioneer. As will be seen, it is a passenger vehicle, but the framing, motor, &c., is on the now well-known and well-tested Symon-House system, and which has frequently been described in our columns. The service was inaugurated on July 1st, when the car made its initial business journey, which was to and from Mansfield Woodhouse, the conveyance being full both ways. On Friday, the 1st, the car ran 26 miles, on Saturday 62, on Monday 60, on Tuesday 44, and on Wednesday 50. On Friday it carried 168 passengers, Saturday 454, Monday 303, and Tuesday 251. It was then found necessary to issue a revised time table. The first one issued scarcely allowed sufficient time for the various journeys. The car has run faultlessly and punctually, and the managing director, Mr. F. A. Robinson, informs us that the takings have exceeded expectations, and those interested in the enterprise will have no reason for regret financially.

When the second car arrives, Shirebrook and New Houghton will

We carried 600 of the above passengers between 1.50 p.m. and midnight on Saturday, which I think is a record in motor work."

The above results are highly satisfactory, and reflect the greatest credit upon Mr. Robinson and Mr. House, jun. Such a useful object-lesson as this cannot fail to greatly stimulate the use of these motor-vehicles, and no doubt many other towns will emulate the enterprise of the Mansfield people.

The well-known tourist agents, Messrs. Cook, have availed themselves of the facilities offered by good motor-vehicles to inaugurate a series of tours to various parts of France. They have secured the Pauline, made by MM. De Dion et Bouton, which took part in Les Poids Lourds last year, and are now running weekly excursions with it from Paris. The first excursion started on the 11th inst.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to THE EDITOR OF "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. KING AND CO., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents:—*

London: Wholesale—BRETT AND Co., 5, Pilgrim Street, Ludgate Hill, E.C.; MUNTON AND Co., 7, Red Lion Court, Fleet Street, E.C.

Birmingham: J. MCCANN, 37, Union Street.

Manchester: JOHN HEYWOOD, Deansgate.

Newcastle-on-Tyne: C. C. ROSS, 35, Side.

Paris: HOMÈRE MOREAU, 97, Rue Nollet.

Victoria (Australia): PHILLIPS, ORMONDE, AND Co., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

Most of the back numbers can still be obtained at 6d. per copy, or 7d. per copy post free.

INDEX TO VOL. I

Is Published Free with the October Number.

NOTICE.—A few copies of Volume I, bound complete, can still be supplied at One Guinea net, in consequence of our having purchased some of the numbers out of print, enabling us to make up some more complete sets.

COVERS FOR BINDING VOLUME I

Price 1s. 6d.*; Post Free,* 1s. 9d.

Can be obtained through the usual Agents, or direct from the Publishers.

Proprietors and Publishers—F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

JULY 15TH, 1898.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month.

[*For particulars of the programme of the Automobile Club of Great Britain, see p.* 415].

1898.	
June 25 and 26	Brussels to Spa Race. Organised by the Automobile Club of Belgium.
July 3 to 11 ..	Race from Paris to Amsterdam, under the auspices of the Automobile Club of France.
July 17 to Aug. 1	Lille (France) Motor-Vehicle Exhibition.
July 30 and 31	Automobile Race, Lille to Boulogne.
August 22 to Sept. 3	Engineering, Machinery, and Motor-Car Exhibition. Royal Agricultural Hall, Islington.
Nov. 18 to 26..	Stanley Show of Cycles, Motor-Carriages, &c. Royal Agricultural Hall, Islington.
1899	Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.
„	Motor-Car Exhibition at Tunbridge Wells.
„	Heavy Motor-Vehicle Competition at Liverpool.
„ October..	Concour des Poids Lourds at Versailles.
1900	Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

A. B. C. (Melbourne).—You had better apply to Mr. Hunter direct. His address is Lewisham, S.E.

J. F. (Coventry).—There is all the difference in the world; in the ordinary wood wheels the spokes are in compression, in the cycle wheels they are in tension.

G. JONES.—We have returned your sketch. We do not think much of your design.

AMATEUR (Manchester).—You do not state your proposition quite correctly. You must express the resistance of the vehicle to traction in lbs. per ton. On ordinary macadam roads this may be taken as 60 lbs. per ton weight of vehicle. We then have—

$$\text{H.P.} = \left(R + \frac{2240}{16}\right)\frac{Wv}{375}.$$

Putting $W = 1$ ton, and $v = 16$ miles per hour, we get $\left(60 + \frac{2240}{16}\right)\frac{16}{375} = 8{\cdot}53.$

To this we must add about 25 per cent., to allow for loss in transmission, and the actual I.H. will be 10·66.

W. S. (Leeds).—(*a*) POCKET-BOOK sent by same post. (*b*) We can supply covers for binding Vol. I at 1*s.* 9*d.*, post free. (*c*) We thank you for your expressions of appreciation and all the new subscribers you have obtained for us, and we wish you every success with your new motor. Your experience with the "intelligent horse" is not exceptional, but what could poor mankind do hitherto when they had nothing else to take its place? Things will now be different, as your own case very clearly proves.

CAR (Kilmaurs).—(*a*) The only English firm which we believe has made the Serpollet boiler is Bernard Samuelson and Co. (Limited), of Banbury. (*b*) The address of the owners of the British patent is the L. R. Syndicate (Limited), 27, Lombard Street, E.C.

CONSTANT READER (Glasgow).—See our reply above to "Car." As to price, &c., you must ascertain from the makers.

R. M. S. (Fleet).—Your only plan is to write to the private address, but the patent rights having been parted with for Great Britain, a vehicle could hardly be supplied direct to you as suggested.

PETROL.—The idea of using milk as an extinguisher for ignited petrol is quite too absurd for discussion. Sand is the most efficient extinguisher. In America and in Russia one always sees heaps of sand near the tanks, but we have never seen a drove of cows.

THE PROGRESS OF AUTOMOBILISM: THE FUSION OF INTERESTS.

JUDGING from the numerous trials and competitions that have taken place so far and which are projected for the near future, there is no doubt that automobilism is making progress, and this opinion is confirmed in every direction. In another column we publish the report of the Liverpool Branch of the S.P.T.A. It will be noticed that it is a record of good work attempted and good progress made in disseminating amongst a somewhat at first sceptical public a knowledge of automobilism. Automobilism is civilisation, and civilisation means the comforts and necessaries of life for all, and those engaged in promoting automobilism are doing more practical work in bettering the conditions of living than all the politicians in the country. Automobilism, unlike those ignoble avocations connected with horses, is an intellectual pursuit, and hence does not, like a shallow and gossipy magazine, a blood-stained drama, or a music-hall banality, appeal to the majority of people and touch them in their tenderest and most susceptible feelings. This explains why the membership of the S.P.T.A. is not large nor its funds superabundant.

The Association nevertheless will have both—a large membership and a large banking account—within a very few years, provided that in these early days its councils are animated by a broad spirit of catholicism and its doings characterised by tact and gentle courtesy, and, let us add, by a careful avoidance of hero worship on the one hand and of a jealous exclusiveness on the other. "In the scientific investigation of self-propelled vehicular and locomotive road traffic" there is work for many minds, and ample scope for the expenditure of much money by those who are, let us trust, hampered not unpleasantly by a superfluity of that commodity—not a few of whom write or can affix the initials M.S.P.T.A. to their names. These remarks will, we think, be not altogether uncalled for by those familiar with the progress of automobilism during the past two years.

We observe with pleasure that the report contains evidence that the principles we have alluded to are likely to be followed by the Association. At present, as is well known, there are three distinct schools of thought in automobilism in this country: the purely scientific and technical, the social, and the financial. Let us be plain. Few people follow a movement from what Huxley terms ethical motives. The majority of us are animated largely by purely cosmical considerations. We are actuated by, let us hope, a spirit of enlightened Hedonism, and from the ethical point of view there is not much difference between the man who works for fame and the man who works for dollars, because each works for an advantage to himself or his *gens*. If while seeking either fame or lucre we can, as is often the case, indulge in our altruistic leanings by all means let us do so, only we need not proclaim the fact on the housetops, nor need we adopt a spirit of pharisaical exclusiveness. We then say that, providing their hands are clean, everyone concerned in automobilism may range themselves under the banner of the S.P.T.A.

Referring to the report, it will be seen that some such line of thought has been operating, and the result is a "contemplated amalgamation or fusion between the Association and the Automobile Club of Great Britain," which it is carefully and naively explained "will in no way prejudice the Liverpool Centre." We should hope not. That this fusion or working agreement will operate to the good of the cause, we make no doubt whatever.

It is, then, with pleasure that we are enabled to announce that this fusion will take the form of an amalgamation between the S.P.T.A., on the one hand, and the Automobile Club, on the other; the two bodies will thus unite under the title of "The Automobile Club of Great Britain and Ireland, with which is incorporated the Self Propelled Traffic Association." We should further explain that the distinctive functions of each body will be maintained, that is to say, the S.P.T.A. section will, as its charter indicates, study the scientific investigation of automobilism in relation to its commercial application, leaving to the younger section the business of popularising the movement, as has so well been done by the Automobile Club hitherto. It must be remembered that the great business of automobilists at present is of an educational nature. We have to educate the public, and this is better effected by ocular demonstration, such as the sight of motor-vehicles running in and around London, than by any other means.

It need not be feared in any quarter that the functions of the Liverpool branch of the S.P.T.A. will in any way be curtailed. This branch of the Association has worthily undertaken special work in relation to automobilism, and, indeed, occupies a position somewhat analogous to that of the various learned societies. We cannot imagine the Royal Institution, for example, as a place where one would seek to pass a few frivolous hours, or where one would endeavour to float a company. Let us, then, look to the S.P.T.A. to supply us with the technical information relating to the practical application of automobilism. The work of popularising the movement and the inauguration of new schemes will more fittingly be undertaken by the great central body in London. For certain purposes a combination of all forces is desirable; thus the whole forces of the united Association will be directed to obtaining an amendment of the Locomotives on Highways Act, whereby all restrictions upon weight shall be removed, as is indicated in the report of the Liverpool branch. We cordially endorse this recommendation. Most automobilists are voters, and not a few are influential ones. A concerted effort, and the intimation gently imparted to would-be County Councillors and members of Parliament that *their* cosmical considerations would be advanced by an amendment of the Act on the lines suggested, would produce the desired result within a single Session. Very few seats in Town or County Councils or in the House of Commons are nowadays what used to be termed "safe." A healthy disbelief in the profession of faith of these representatives is permeating the public, and between the "independent judgment" of the man with a safe seat and the complaisant acquiescence of the man with a less secure one there is a great difference, which should at once be taken advantage of. No doubt the new organisation will look to this and kindred matters. In conclusion, the Association ought to be a power in the land, and it will be the fault of its members if it is not.

TRACTIONAL FORCE.

ONE of the most important points about any motor is the amount of work it absorbs in overcoming internal friction. This work, of course, represents so much loss, and it forms a large proportion of the difference between the indicated and brake-power of a motor. In motor-vehicles, owing to the roughness of the roads, the power can seldom be applied to the wheels directly, but through a mass of gearing, which means a large number of sliding surfaces which are frequently under considerable pressure. We then have considerable power absorbed by the differential gear, dirty or badly worn chain transmission gear. It is, therefore, certain that in motor-vehicles the loss due to these causes must be very great. It was with a view to obtaining some information as to the gross loss in motor-vehicles, that is, the difference between the indicated and the brake-power, that we recommended that brake tests should be carried out at the Liverpool trials. Another test that might have been made at Liverpool was the determination of the element of tractional force for each vehicle. We cannot but regret that these tests were not made, as without them the trials must be considered as incomplete. At the Birmingham trials this latter test was made by Professor Unwin, and in due time the information will be published, and it should prove exceedingly valuable and interesting. The test in question is not difficult to carry out. It consists in letting a vehicle descend an incline freely under the action of gravity only, and in virtue of its kinetic energy ascending another.

Two gradients of known length and inclination are selected, and the vehicle allowed to descend and ascend freely.

Let—

W be the weight of the vehicle in lbs.
d the distance it runs freely in feet.
h the vertical height through which it falls.
a the angle of grade
T the tractive force in lbs. exerted.
R the frictional resistance.
μ the coefficient of friction.

Then—

$$T = Wh \text{ (foot lbs.)}$$

$$R = \frac{Wh}{d} \text{ (lbs.)}$$

$$\mu = \frac{h}{d}$$

This experiment should be made for the same vehicle under varying conditions of grade, load, and mechanism, and the results plotted on a curve. The information so obtained would be of the very greatest service to designers and would, if intelligently applied, greatly facilitate the adoption of automobilism in many quarters.

THE FLASH POINT OF PETROLEUM.

By GEO. HERBERT LITTLE, C.E., Author of "The Marine Transport of Petroleum," "The Transport of Petroleum in Bulk in Tropical Waters," &c.

THE principle enunciated in the aphorism that "the safety of the public is the supreme law" is the basis of all true legislation. While the wise application of this principle has effected an enormous improvement in our general social well-being, attempts are made from time to time to inaugurate legislation supposed and intended to benefit a section of the public, but at the expense of the public at large. This abuse of a sound principle is at all times to be deprecated, but when, as has not infrequently been the case in recent years, important commercial interests are thereby affected to the benefit of the foreign competitor, and with no particular advantage to the class for which the legislation was undertaken, it becomes the duty of everyone to carefully examine all such fresh proposals for what we may term philanthropic legislation, in order to see that neither the interests of the State nor of any section composing it are prejudiced. Everyone familiar with the industrial legislation of the last 20 years must know that the benefits, real or supposed, that have accrued to the class legislated for have been accompanied in most instances by a transference of a certain volume of trade from our hands to those of our foreign competitors. Take, for instance, the Load-line Act. This was the outcome of a purely hysterical agitation. Its object, laudable enough, could have been accomplished by other than legislative means. Yet its effect has been to give a tremendous impetus to the commercial marine of foreign States at the expense of our own foreign carrying trade. Much of our excellent factory legislation has operated in the same way, as the Lancashire cotton-spinning industry has found out. In their zeal to promote what, in the cant of the day, they love to term "legislation of a remedial and beneficial character for our toiling masses" all political parties vie with each other, and to this end cheerfully precipitate grave commercial consequences which no one can foresee.

"What if my house be troubled with a rat and I be pleased to give ten thousand ducats to have it baned?" said Shylock, with irrefutable logic; similarly not a few of our legislators say, in effect, What if our State be troubled with some form of industrial evil and we be pleased to sacrifice commercial advantages to have it removed?—only in this case the logic is not apparent. Nevertheless we do so, and it is a very grave question whether we are wise in so doing, especially in view of the growing fierceness of foreign competition, hostile tariffs, and the like.

It will be news to many to learn that our trade is shrinking, but such is the fact. According to a recent official report on the trade and industries of Great Britain made to the Foreign Office, it appears, as the result of very careful inquiry, that our position has "retrograded in relation to the other great nations. . . . . In nearly every important department of industry our proportional share has much diminished." *

In view of these conclusions we are now asked to impose a burden upon the great petroleum industry of this country, not, be it observed, for the benefit of the public at large, but entirely in the supposed interests of that section known—to employ the usual jargon—as the "toiling masses," and the ostensible reason for this is that much loss of life occurs, chiefly among the labouring class, from the use of burning oil having a low flash point.

That such a loss of life does occur is an undoubted fact, but in the explosions, fires, &c., occasioning the deplorable loss of life, there are four factors nearly always associated; they are:—

(*a*) The use of a petroleum having a low flash point.
(*b*) The use of a lamp of wholly improper and unsafe construction.
(*c*) Improper use of the lamp, *i.e.*, badly-fitting wick, turning wick into the oil when the former is alight; blowing down chimney, &c.
(*d*) General intense ignorance of the properties of petroleum and the principles of combustion on part of users.

It is of little use to describe the history of the agitation which, originating from a few newspapers of the baser sort and carefully fostered by them since, resulted in the appointment, some two years ago, of a Committee of the House of Commons to inquire into the whole question of the use of petroleum. Neither is it of much use to discuss the very voluminous and, for the most part, unreliable evidence that was given. Some scientific evidence was produced to show that the flash point should be raised, but this evidence was of a purely academic nature, and none has been produced to prove that lamp accidents occur *only because* low flash oil is used.

Of course, as a general rule, all articles of consumption should be rendered innoxious, and inasmuch as raising the flash point makes the oil safer to handle, much can be said in favour of doing so. On the other hand, we have the great fact that low flash oil is used in thousands of homes with perfect safety, and the other fact that it is only dangerous when used with a total disregard of the dictates of ordinary common-sense. Hence the question of raising the flash point *because* a low flash oil is dangerous is really a very open one upon its merits, and only to be decided in the affirmative on other grounds. The Committee have, after much deliberation and by a very narrow majority, decided to recommend the House of Commons to raise the flash point from 73° F. to 100° F. (18 C. to 30 C.). Whether the House will consent to do so remains to be seen, but if it does, will the ostensible object in view be effected, and will the general trade of the country in petroleum be prejudiced in any way? We reply to the former, No; and to the latter, Yes. To assume that these lamp accidents would be prevented by raising the flash point to 100° F. is not only a wholly unwarranted conclusion *per se*, because unsupported by evidence, but is also to put an encouragement upon carelessness and ignorance. But the great effect of raising the flash point as proposed would be far more reaching and extensive; it would mean a generally enhanced price of burning oil to the consumer and the exclusion of a most useful class of mineral oil much used in industries for other purposes than for lighting.

Thus the cost of using petroleum as liquid fuel by automobilists and others would be quite prohibitive, and the same remark applies to its use in oil motors. Users would be compelled to employ a high flash test and expensive oil when a cheaper and practically as safe an oil would be just as, indeed more, efficient. Ordinary petroleum burning oil, as now sold with the 73° flash point, would have to be classed as a mineral spirit, which it is not, and this would mean endless worry, trouble, and expense with the local authority as regards license and storage.

The present large trade in distributing a cheap and, if properly used, a safe and reliable illuminant would be curtailed and crippled; this would mean diminished employment, and so would react upon the very classes for whose benefit the alteration is to be made.

At present we obtain the bulk of our lamp-oil from the United States, and this is a fairly cheap article of commerce—it might be cheaper. American crude oil yields about 75 per cent. of burning oil. Russian oil yields not more than 30 per cent., and although this latter is more homogeneous and has a higher flash point than the former, yet it is not so suitable as the former, either as an illuminant or as a source of energy in oil motors. The effect of raising the flash point would increase the Russian production and exportation, and, therefore, the Russian revenue. Now, Russia excludes our metal ware and our coal, and has announced its intention of forbidding Russian subjects to purchase ships, &c., built in Great Britain. Why, then, should we go out of our way to take more of her products than we can help? It has been stated that Russian oil of 103° F. flash point can be placed on the home market at the same price as that now charged for American 73°. No doubt it will till such time as we legalise the 103° F. test. An "arrangement" or "working agreement" would then be entered into between the powerful oil interests of New York on one hand and those of Paris and Vienna on the other to divide or exploit the market, and maintain a standard price which would have to be higher than that now charged for 73° test oil. In other words, we should not greatly, if at all, lessen lamp accidents, but we should pay more for our oil.

Much, too, has been said about the supply of American oil being in the hands of a group of monopolists. If we raise the flash point we simply play into the hands of another group of monopolists, and we may be sure that with the British market at their feet these two groups will not quarrel much.

A small but influential competitor with these two groups of monopolists is the Scotch shale oil industry. This industry has all but been wiped out by the cheaper American products. Naturally, the Scotch Parliamentary "interest" is much impressed with the necessity of raising the flash point, and profess a really touching solicitude for the poor working-man, whose life and the lives of his family are said to be jeopardised by the "deadly 73°." If the flash point is raised, it will in effect be the same as a protective tariff to an industry. Why should we protect the Scotch shale oil industry any more than the Scotch sugar or the Lancashire cotton industries?

In conclusion, we say that no sufficient reason has been shown why the present flash point of petroleum, 73° F., should be raised to 100°. We must remember that on the Continent, especially in Germany, Austria, and France, the flash point of oil used in lamps is about 6° lower than that at present sanctioned by law in this country. Again, in France vast quantities of petrol (a mineral spirit which flashes at the freezing point or a little above) are used in motor-vehicles. Yet accidents on the Continent are exceedingly rare, and the reason why there is this immunity from such accidents as those we in this country are so familiar with, and which form such an inexhaustible mine of sensational "copy" much appreciated by the "Yellow Press," is largely because the Continental working-man is much better educated than the British working-man, the instruction that the former receives as a boy being more technical and practical than

* *Vide* Report of H.M. Consul at Stockholm.

that given in our schools. The remedy for lamp accidents is, then, not to impose an unnecessary burden upon an industry, and therefore upon the general community, but to improve the education of the workers.

The French Motor-Cab Trials.—In our present issue a very full account of these will be found. These trials are beyond question the most exhaustive and have greater scientific value than any trials of motor vehicles yet conducted. For this reason we devote so much space to them, as the data and analysis we are fortunately enabled to publish cannot fail to be of the greatest possible value to constructors and designers. For this reason, too, we are obliged to hold over many matters of lesser importance.

The Judges at the Birmingham Trials.—It would have been difficult, if not impossible, to have selected three greater authorities on automobilism than the distinguished engineers, who, with commendable discrimination, were chosen by the Council of the Royal Agricultural Society to conduct the trials of motor-vehicles at the Birmingham Agricultural Show. They were Professor W. C. Unwin, F.R.S., without exception the greatest living authority on scientific engineering, especially in its later developments; F. W. Webb, M.I.C.E., &c., of Crewe, the distinguished and successful locomotive engineer of the London and North Western Railway Company; and Bryan Donkin, Esq., M.I.M.E., &c., the well-known authority on combustion, whether in steam boilers or gas and oil engines, and in other ways a most distinguished investigator, and lot us add, a pioneer automobilist. These three gentlemen constituted a Court, to which no possible exception could be taken on any ground, of the very highest professional eminence. Their opinions on automobilism will be unhesitatingly accepted both by competitors and the public. We sincerely trust that these gentlemen will be called upon to exercise their judicial functions in future competitions and trials of motor-vehicles as their professional standing is such as to constitute the best guarantee, not only of the highest scientific and technical knowledge, but also of absolute judicial impartiality.

Boilers for Motor-Vehicles.—In our present number we give the official report of an inquiry held to determine the cause of an explosion of a Field tube in a tramcar boiler. As small boilers will be extensively used in the near future for motor-vehicle purposes, it behoves all concerned to take care that the boilers are not only of the best possible make, but that they are opened out at least once a fortnight and carefully examined by a skilled boiler-maker and worked only by a skilled fireman. In the present case no loss of life occurred, but had this boiler been less well looked after an explosion might have been attended with the gravest consequences. These small boilers deteriorate very rapidly; they are, at least those working under the Locomotives on Highways Act must be, of light scantlings, hence the factor of safety, say after a spell of prolonged service, cannot be high. On the other hand, the legal liabilities incurred by owners are very onerous, and hence too much care can hardly be taken by them. We suggest that in every case the boiler should be insured in a good company and the suggestions of inspectors rigidly carried out. We would also urge the importance of using the best procurable water, or if this be difficult, the appearance and formation of scale should be carefully watched and suitable solvents used such as would be recommended by a competent analytical chemist. Lastly, owners of steam motor-vehicles must remember that their boilers work under conditions very much more severe than obtain in the case of railway locomotive, traction, steam-ship, steam-launch, or torpedo-boat boilers. It is in this connection that we see the egregious folly of the Legislature in limiting the weight of vehicles to 3 tons, this means small and light boilers, whereas with a more liberal allowance as to weight, a much larger, stronger, and easier steaming boiler could be provided, and such a boiler would be very much safer.

Harmsworth's Magazine.—Messrs. Harmsworth are always up to date. The introduction of their *Daily Mail* was a revelation to the newspaper world. Its success must have seriously encroached upon the circulation of some of the old-established morning dailies. Their latest publication, *Harmsworth's Magazine*, sold at 3*d*., is a marvel. It is brimful of good things, and a significant sign of the times is the crisply-written short tale by Edgar Jepson, illustrated by H. R. Millar, entitled, "Their Motor-Car Elopement and How it Ended."

AUTOMOTOR VEHICLES AT BIRMINGHAM.

Second Notice.

[FROM OUR OWN CORRESPONDENT.]

When writing to include some particulars of these trials in our June issue, we left the heavy vehicles *en route* for Fazeley, the Daimler van having completed the run. We then investigated the state of the Roots and Venables van, which had been run into about a mile from Bassett's Pole by a non-competing car carrying a party witnessing the trials. The collision damaged the steering gear of the former, causing the van to run into the ditch. The incident was most regrettable for many reasons. After considerable delay the judges were "recovered" from their lunch and brought to the scene of the mishap.

In due course the van was extricated, and with some difficulty it was run back to the Pole and left in the yard of the inn. *hors de combat* for the rest of the trials. Owing to minor damages incurred during its railway journey to Sutton, it had started on its run without a load, and under the circumstances this was fortunate, as otherwise the accident might have caused more costly and extensive damages. As it was, the occupants had a severe shaking.

We then proceeded (thanks to the kindness of Mr. Grimshawe) to run out in the opposite direction to meet the heavy vehicles. Before long we met the Chiswick van running quietly and steadily, and about a mile and a half further on came upon the Leyland lorry. Having given them the road, we followed leisurely until we met the judges' wagonette, which had also come out to meet the vans. Running ahead, we soon reached Bassett's Pole again, to learn that the Chiswick van had done the run in 2 hours 29 minutes. The Leyland lorry arrived soon after, having covered the distance (13¼ miles) in 2 hours 32 minutes.

On Tuesday the crucial test of a 52-mile run was carried out. The course was as follows:—First, round the same course as on Monday; then reverse and run back for about five miles, when a detour was made so as to take Atherton and Coleshill, until the old route was touched at Wishaw, and thence back to Bassett's Pole. In this way the stretch from the Pole towards Wishaw (which for about six miles was a typical rutty, grass-grown country road) was traversed three times. By about 9.25 a.m. the Daimler and Chiswick vehicles were at the Pole, the Daimler leaving at ten minutes to 10, followed by the Chiswick van two minutes later. At 9.55 the Leyland lorry was likewise off, the rear being brought up by a goodly collection of motor-cars, motettes, and cycles. Near Atherstone one of the judges mounted the Daimler van, stopping it on steep hills and on inclines, making it run backwards up the latter, and generally testing its capabilities. It successfully achieved all the tests imposed, thus securing the first prize (£100) in the 1-ton class, after which it ran home without a hitch, covering the distance in six hours, consuming 2 gallons 6 pints of petrol, costing about 1*s*. 9*d*.

In the meantime the heavy vehicles had been coming along well. Between Atherstone and Coleshill the Leyland lorry passed the Chiswick van, the latter beginning to show some signs of distress owing to the hilliness of the route. This was particularly noticeable at Coleshill, where a long, and by no means contemptible, gradient terminates in a sharp rise, practically equal to something between 1 in 7 and 1 in 8. At this point the Chiswick van was certainly overloaded and had to be eased, but it is only fair to state that the van was built for a load of 2½ tons (which it carried at the Liverpool trials), whereas it had to take 3 tons at Birmingham. It is evident 2½ tons is its maximum load for anything like hilly districts.

In due course the two heavy machines were put through their facings on the hills and allowed to proceed. The Leyland van ran without further incident of note to Bassett's Pole in seven hours, having consumed 23¾ gallons of petroleum and evaporated 165 gallons of water, with an average speed of 8 miles per hour. It is interesting to note that it made the "inner circle" of the course 25 minutes quicker than on the previous day, while the Chiswick van took nearly 35 minutes longer, having suffered several delays.

At the Liverpool trials the Leyland lorry had a breakdown through a loose tyre, leading to a collapse of the wheel; but in answer to special inquiries on this point, we were assured that the same wheel was still on the lorry (after being duly repaired) and had carried the lorry safely to the goal which the makers coveted, viz., the £100 prize.

It was 15 minutes past 8 p.m. when the Leyland van returned to Bassett's Pole, but owing to difficulty with the hills it was considerably after 10 p.m. before the Chiswick competitor reappeared. Bearing in mind, however, the fact that it had knowingly overtaxed itself it was plucky to stick to it and run out the course, which it did in a manner that evidently satisfied the judges, who acknowledged its undoubted merits by the second prize of £50. Owing to the unexpected nature of some of the delays the actual running time could not be properly estimated, but the consumption of coal was about 8½ cwt.

Wednesday was devoted to tests, made with a view to calculating the power absorbed by the mechanical friction of the vehicles and motors, the latter being thrown out of gear, when the vehicles were run down one gradient, and a note taken of how far they ascended the next. The results of the calculations made from the data so obtained will be given in the judges' report.

Exhibits in the Show Yard.

Apart from the collection of motors in the show yard, where the Daimler, Roots and Venables, Saunderson, Leyland, and Chiswick (Thornycroft's) vehicles were shown in a group to an admiring and inquisitive crowd, there were a few exhibits of general interest to automobilists.

Messrs. W. Glover and Sons (Limited), Warwick, who are makers of liquid manure and general farm carts, were showing their patent watering van, which, in addition to being excellently made and finished (the wheels being of the gun-carriage type), is arranged to be driven with motor instead of being drawn by a horse. The body is carried on a steel frame in the front of which is neatly fitted a pair of 4 N.H.P. Daimler motors, the cooling water cylinders being in the body of the water-cart tank itself. It is capable of running at two speeds, and is altogether a shapely and capable watering cart. It is credited with 11 B.H.P. and priced at £400.

Messrs. Coulthard, of Preston, showed three small compound steam motors, distinguished by careful designing and attention to details. The lubricating arrangements have been worked out with much care, there being sight-feed cups to each part, and all being shut off by a single cock when the engine is stopped. The eccentric rod and the connecting rod are hollow, and oil is fed down through them to the eccentric and crankpins. There is a piston valve to each cylinder, and the crank races are boxed in to prevent splashing. Steam is supplied by a water-tube boiler, made by Mr. W. Sargeant, the well-known steam-launch builder and engineer, of Strand-on-the-Green, Chiswick. This boiler has 85 square feet of heating surface, and is of the same construction as that recently illustrated in THE AUTOMOTOR.*

Another exhibit of the automotor class which might easily have been overlooked by even the interested visitor, as it was not shown at the "Motor Stand (No. 502)," was a steam tipping wagon, made by Messrs. Mann and Charlesworth, Leeds. In appearance it resembles a small traction engine with a tilting-wagon body placed over the two back wheels. The latter are extra wide, mounted on springs. It is fitted with the makers' patent single eccentric reversing gear. The motive power is steam with compound engine. In addition to being used as a steam tumbril, it is capable of being employed for hauling and thrashing. It carries a load of 3 tons, and is built so as to comply with the Locomotives on Highways Act of 1896. Price £330.

The West Patent Power Tyre Setter Syndicate were showing their hydraulic tyre setters at work and collection, and steel and rubber-tyred wheels also being on view. The machine is capable of hooping wheels up to 6 feet in diameter, with tyres up to 6-inch face and 1¼-inch section. Wheels can be hooped at the rate of 25 per hour for a cost of about 1½*d.* per wheel. As no fire is needed, the tyres being fixed when cold, it is just as cheap to fix one tyre at a time as to fix 50. The accuracy and rapidity of the machine have been greatly augmented by the recent modifications in the trip gear and exhaust cock. A new form of light tyre setter for carriage builders was also shown in conjunction with an hydraulic wheel boxing press.

THE JUDGES.

F. W. WEBB, ESQ., M.C.I.C.E., M.C.I. and S.I., &c.   PROF. W. CAWTHORNE UNWIN, F.R.S., M.I.C.E., Hon. M.I.M.E.   BRYAN DONKIN, ESQ., M.I.C.E., M.I.M.E., &c.

The Oldest Steam Motor in Existence.—The oldest engine in the world is in the possession of the Birmingham Canal Navigations, this engine having been constructed by Boulton and Watt in the year 1777. The order is entered in the firm's books in that year as a single-acting beam engine, with chains at each end of a wood beam, and having the steam cylinder 32 inches in diameter with a stroke of 8 feet, and erected at the Canal Company's pumping station at Rolfe Street, Smethwick. During the present year (1898) this remarkable old engine, which has been regularly at work from the time of its erection to the current year, a period of, say, 120 years, was removed to the Canal Company's station at Ocker Hill, Tipton, there to be re-erected and preserved as a relic of what can be done by good management when dealing with machinery of undoubted quality. It is worthy of note that the Birmingham Canal Navigations favoured Boulton and Watt in 1777 with the order for this engine, and in 1898, or 120 years afterwards, the Company have entrusted the same firm, James Watt and Co., Soho, Smethwick, with the manufacture of two of their modern triple-expansion vertical engines, to be erected at the Walsall pumping station, having 240 H.P. and a pumping capacity of 12,713,000 gallons per day.

LAW REPORTS.

British Motor Syndicate v. Universal Motor-Carriage and Cycle Company.

ON July 1st, before Mr. Justice Stirling, the hearing of this action, brought by the British Motor Syndicate (Limited) against the Universal Motor-Carriage and Cycle Company (Limited), for alleged infringement, was commenced. The hearing occupied several days.

Mr. Fletcher Moulton, Q.C., Mr. Bousfield, Q.C., and Mr. Walter appeared for the plaintiffs; Mr. Phipson Beale, Q.C., Mr. Shaw, and Mr. White appearing for defendants.

Mr. Moulton said that this action was brought by the plaintiffs, as the owners of four patents relating to motors for motor-cars, for the infringement by the defendants of these patents. He need not trouble his lordship with the fourth patent mentioned in the statement of claim. On going into the matter, plaintiffs had come to the conclusion that they could not support the claim of infringement. Therefore, his lordship might consider it as struck out. He would first deal with the Patent No. 9,112 of 1884, granted to Lawrence A. Groie on communication with Gotlieb Daimler, a German inventor. That patent had expired since the bringing of the action. As far as the damages were concerned, the rights of the plaintiffs remained unchanged; it only affected their right to an injunction. He could explain the nature of the invention very simply. It related to gas-engines, and what were called Otto gas-engines The Otto type was the first successful engine. There was a motor struck an explosion every second stroke, and the cycle was this: Starting from the moment of the explosion the piston was driven out by the effect of the explosion, and when it came to the end of its stroke it opened the exhauster. The gas was under greater pressure during the explosion. The piston returned, driving before it out of the exhauster the products of the exhaustion. It then started forward, by the motive of a fly-wheel. It went forward, creating a suction behind it, which drew in the charge for the next explosion, a mixture of air and gas. When it went to the end of its stroke, carried forward by the fly-wheel, the fly-wheel went on and drove it back, all the valves being shut. Then it compressed a mixture of air and gas, which was to give the next explosion, into the back part of the cylinder. So you had an explosion of compressed air and gas. When that took place the cycle he had been describing recommenced. His lordship would see the importance of the introduction of the principle of compression. When you raised the gas to a certain temperature it made no matter. The increase of temperature was independent of whether the gas was compressed or not. It was a very great advantage in this engine that you started with the air and gas under compression at the moment of explosion. Otto, by the introduction of this cycle, made the engine a very great success. The patent in question related solely to engines of this type. That was put quite clearly in the complete specification, and also in the claim. The next point with regard to the gas-engine to which his invention related was the question of ignition. It was necessary it should be ignited at the moment of explosion. If it had not been compressed the problem of ignition would have been easy; but as it was under compression and the cylinder was closed, there arose the difficulty of how to obtain ignition. Otto devised an ingenious gas slide. It effected ignition by moving backwards and forwards at the end of the cylinder. It had a flat face and a pocket. Just before the moment of ignition was intended to take place this little pocket got filled with air and gas, and so ignited at a small gas flame, and the handful of lighted gas was carried beside the hole it lighted into the cylinder. So a match of air and gas was applied once to every two strokes, carrying this handful of burning gas, which arrived at the hole which led into the cylinder at the right moment for making an explosion. No doubt that was a very great invention; for 14 years it practically held a monopoly, although many variations were introduced. But the gas slide, though a useful invention, had the disadvantage that the slightest scratch on the face would make it fail to light. It was a matter of great importance to get rid of this system of ignition by means of a pocketful of ignited gas. A great many suggestions were made. In 1884 Daimler made an extraordinary advance on the valves that had been used as substitutes. This invention drove out the gas slides, and almost entirely all substitutes. It was effected thus: The compression by the gas into the back stroke raised the temperature for one thing, and, of course, put it under considerable pressure. It was found that it required a body of a lower temperature to light gas when it was compressed than it did if it were not. A smaller temperature of the igniting body sufficed to cause an explosion. Daimler took advantage of this, and by means of ignition tubes he arrived at an enormous simplification. This simplification, when applied to motors for motor-carriages, was of great value. By far the largest number of gas-engines were now fitted with these ignition tubes instead of any of the other means for igniting the mixture of air and gas.

Mr. Fletcher Moulton, having dealt with the nature of explosion-engines, proceeded to deal with flame-engines. With these there was no explosion, but there was combustion. His lordship, the learned counsel said, could imagine a stream of gas and air, under pressure of 20 lbs., passing through a tube till it came to something which lit it, and ignited the cylinder. The consequence of this combustion was that there was an enormous explosion of the air and gas, on account of the air and gas generated. Supposing that these products of combustion were still kept at a pressure of 20 lbs., this explosion would mean the driving forward of the piston. In the explosion-engines you got the explosion intermittently and then drove the piston, but you could get it also by this gradual explosion in the same way. That was the distinction between flame-engines and explosion-engines. The whole beauty of Daimler's invention was getting rid of any time mechanism. This allowed compression to take place at its own time without any mechanism at all. Passing on to the next patent, 4,315 of 1885, that was again a patent of Daimler. This was a device for regulating engines. Gas-engines were very much more difficult to regulate than steam-engines. You must have everything in at the moment of explosion. Although a great number of methods had been tried to alter the richness of the mixture, the quantity of explosive charge, they did not seem to succeed. Practically the whole regulation of gas-engines depended upon what might be called a crude method of missing strokes. He did not think any method had really succeeded which graduated the effect of the strokes. These strokes were all taken on their full force, but if the engine were going a little too quickly it had a governor which made it miss strokes sometimes. These were called "hit and miss" regulators. Most engines had this hit and miss regulator, but Daimler conceived the idea of regulating, not by means of affecting the entry, or rather the inlet valve, but by indirectly affecting it through the exhauster. When the engine went too quickly he had an apparatus which locked up the exhauster. The consequence of locking it up was this: the products of combustion could not get out of the cylinder, and the consequence of that was there was always a considerable pressure in the cylinder. He left his inlet valve to work automatically by suction. When he had locked the exhauster valve there never was any suction, so it lost a stroke. This was clearly described in the claim—the method of regulating the speed of gas-engines by causing the discharge valve for the product of combustion to remain closed when the normal speed was exceeded. It did not pledge itself to any particular method of locking the exhausted valve—there would be a hundred different ways of doing that; but the invention was for preventing admission by locking the exhauster out. He did not think there was any anticipation of that claim. The third and last patent that he had to put before his lordship was 10,786 of 1885. This was another early patent by Daimler. He was the first man to conceive the idea of motor-bicycles. These motor-bicycles were now quite practicable. They were not yet largely used, but yet they were being made in fair numbers. Daimler contrived his motor machinery to fit centrally between the two wheels. The claim for infringement related to this patent combination of a vehicle having a driving and steering wheel, running on the same track, with centrally-arranged motor-engines in which was the regulator. The centre of gravity lay in a vertical plane with the wheel track. He put his engine between the central line in the way described. It appeared that it was perfectly novel to fit a motor to a bicycle. Motors fixed to bicycles must be fitted in this way. Mr. Daimler was the first person to show that it was possible to make a bicycle which had no fixed wheel base at all work with a petroleum or gas motor. With regard to the first patent, the ignition tubes, there could be no question but that there had been an infringement. Evidence of a highly technical character was then given.

Mr. John Imray said he had given a great deal of attention to gas-engines. He had also made a study of motors. The great difficulty of these engines was the question of ignition at the right moment. The first gas-engines were ignited by electricity. Then came the Otto method with the face and pocket. That was ignition by a properly-timed igniting mechanism. Another form largely used was heating a tube in connection with the cylinder. But there you had again a properly-timed mechanism. But the mechanism must move at the right time. The plaintiff's invention of 1884 was a much more simple arrangement. Whenever the compression of the charge in the cylinder was completed the contact of the gas with the heated tube was complete. When the gas and air were compressed they would ignite at a much lower temperature. This was of much use in motor-engines. The cycle referred to in the claim was of this character. He did not know of any motor bicycle before the date of the plaintiff's patents. In cross-examination he said he had seen the Daimler machines at work, and also those described in Grote's patent, and in further cross-examination the counsel made a strong point of suggesting that there was a serious discrepancy between Daimler's provisional and complete specification. Mr. Imray also gave evidence as to the anticipations of Daimler's patent, which had been relied on by defendants. Speaking of the patent 4,803 of 1878, he said that in his opinion the specification was strictly limited to the "Otto" cycle.

Mr. A. J. Bolt, the next witness, generally corroborated the evidence of the last witness. In cross-examination witness thought that the Daimler was an example of an engine which worked on the principle of spontaneous combustion, and which had no further devices than those which were shown in Grote. He also admitted that the use of the priming cap was equally applicable to any engine having compression of the explosive charge, whether on the "Otto" cycle or otherwise. Whilst being further questioned on the part played by the governor in Daimler's mechanism, Mr. Justice Stirling interposed, saying:—"The facts, as I understand, are not in dispute as to the *modus operandi*. No doubt your valves are open and theirs are shut, and the point between you must be reduced to one of law, partly in the construction of this claim and partly in the discovery of whether you are the user of an infringement." Witness further admitted that the real purpose effected by Daimler was old, and effected in a special way. He did not agree that the defendants effected their purpose in an exactly opposite way.

Mr. Harry J. Lawson, managing director of the plaintiff Company, was the next witness. In the course of his evidence he mentioned that he owned more motor-cars, he believed, than any other man in the world. He had also five motor-bicycles, and that the patents for the motor-bicycles were purchased by the plaintiffs for a large sum of money. He claimed that no one besides Daimler had successfully combined a bicycle with the arrangement as devised in the plaintiffs' patent. The question of the disposition of the parts was one of enormous importance. Daimler had been 20 years perfecting his invention.

Mr. W. Worby Beaumont, C.E., gave technical evidence corroborating the plaintiffs' claim.

The defence was then opened, the first witness called being Mr. James Swinburne, C.E. He stated that Crossley's and Atkinson's inventions appeared to him to be anticipations of Daimler's.

Mr. Anthony G. New, was carried through a very minute examination and cross-examination in respect to the ignition tube arrangement, mention being made of the Pygmee ignition arrangement.

Mr. Swinburne was recalled for cross-examination by Mr. Fletcher Moulton, Q.C.

On behalf of the defendants Mr. Shaw submitted that the plaintiffs' claim was bad. He contended that the defendants had committed no infringement. They could not have infringed a claim which had been so narrowly construed. In the first claim, the vehicle was spoken of as a bicycle, and in the second as a motor-bicycle. There could be no subject-matter in enclosing the machinery of a bicycle in a casing.

Mr. Fletcher Moulton replied very fully on behalf of the plaintiffs, and at the conclusion, on Friday last, a difference of opinion having arisen between Mr. Moulton, Mr. Shaw, and his lordship upon the construction to be placed upon some of Mr. Swinburne's evidence, before considering the entire evidence, Mr. Justice Stirling decided that he should like to have Mr. Swinburne recalled so that he might hear from him personally the meaning he really intended to convey.

The case was therefore adjourned until this week, after which his lordship will probably take some little time before delivering judgment.

Lord Galloway and the Lamina Accumulator Syndicate.

IN the Chancery Division, on the 8th inst., before Mr. Justice Kekewich, Mr. Warrington, Q.C., moved in the matter of the Lamina Accumulator Syndicate and the Lamina Accumulator Company, on behalf of the Earl of Galloway, for the appointment of a receiver. The Company were the purchasers of the assets of the Syndicate, by whom the debentures held by the Earl of Galloway were granted, and counsel said they were threatening to place a charge of £4,500 on these assets in priority to the debentures in question. A motion came before the Court originally on June 10th, and stood over on terms, in pursuance of which the Lamina Accumulator Company had paid £1,000 to the bankers for Lord Galloway's security and interest on the debentures down to June 30th; but they had made no payment in respect to the principal of the debentures, nor had they done what they were bound to do under the agreement—issue to Lord Galloway debentures in the Company in lieu of the debentures he held in the Syndicate.

Mr. Bramwell Davis, Q.C., who appeared for the Lamina Accumulator Company, said they were anxious that Lord Galloway should receive these new debentures, but they could not get the liquidation of the old Syndicate to complete the matter.

Mr. Cutler, Q.C., appeared for the Lamina Accumulator Syndicate, and said that, before completing, the liquidator required certain small accounts to be paid.

Mr. Justice Kekewich, by consent, ordered the motion to stand over for a fortnight, the Company undertaking not to create any prior charge pending the issue by them of the debentures in question.

A Motor-Car Accident Action.—Issues were ordered on June 28th by the First Division in an action in which Alex. Lang, watchmaker and jeweller, Larkhall, sues the Scottish Motor Omnibus and Car Company (Limited), 66, Cadzow Street, Hamilton, for payment of £1,000 damages in respect of personal injuries. The pursuer states that the defenders have established a constant service of motor-cars between Hamilton and Larkhall for the use and accommodation of the travelling public. On Thursday, December 23rd last, the pursuer was a passenger by one of the defenders' motor-cars run by them from Larkhall to Hamilton. When near High Merryton farm steading, the car was driven in such a manner that it suddenly swerved and was then capsized, with the result that the pursuer was thrown violently on the road and sustained serious injuries. The pursuer avers that the defenders were at fault in entrusting the charge of the car to a lad who was inexperienced and unskilled in the art of driving such a car. The defenders admit that the accident was due to the driving of the car by the lad, but they say that they appointed an experienced and qualified driver, and it was he who allowed the lad to control the car on the occasion in question. They deny liability, but in order to avoid litigation they offer the pursuer 20 shares of £1 each of the Scottish Motor Hiring Company (Limited), in full settlement of his claim.

The British Motor Company (Limited) *v.* Stokes.—In the City of London Court on June 28th Mrs. Caroline Stokes, Park Street, Southend, was sued by the plaintiffs, of 40, Holborn Viaduct, for £5, calls on shares. Mr. Aldous, for the defendant, said that the signature to the application for the shares was a forgery. The plaintiffs could only prove that the application came by post in the ordinary way. They did not know the defendant's signature. They were consequently nonsuited, and ordered to pay the defendant's costs.

The Great Horseless Carriage Company (Limited) *v.* Pallett.—The plaintiffs, of 40, Holborn Viaduct, in the City of London Court, on June 17th, before Mr. Commissioner Kerr, sued Mr. Richard E. C. Pallett, 83, Paris Street, Stoke Newington, for £17 12s. for calls on shares. The defendant objected to pay on the ground that there had been fraudulent misrepresentation on the part of the directors. This was denied by the solicitor for the plaintiffs. As a similar point bad been raised in the High Court in a case which was going to the Court of Appeal, this action was adjourned.

The Great Horseless Carriage Company (Limited) *v.* Flanagan.—In the Queen's Bench Division (Dublin), before Mr. Justice Gibson, Mr. M'Auley (instructed by Messrs. Maguire anp Riordan, Belfast) applied on behalf of Mr. Patrick Flanagan, who resides in Belfast, for leave to put in a special rejoinder to plaintiffs' reply. The action is for £215 for calls on shares A defence was put in alleging that the defendant was misled by the prospectus, which he stated was false and fraudulent. The plaintiff's reply stated that the Company had been wound up, and that consequently the defendant could not rely upon these alleged fraudulent particulars in an action for unpaid calls. Mr. Justice Gibson asked if the action was brought by the liquidator. Mr. M'Auley replied that it had been brought by the Company alone. The liquidator did not appear in it until the delivery of the reply, and the defendant wanted to plead that this winding up was only part of the swindle. Mr. Justice Gibson said he would not like to give leave *ex parte*, but he would allow the defendant to serve a short notice. Counsel, however, should reflect as to what form the notice would assume, and meditate anxiously over the views of the House of Lords in Derry *v.* Peek.

Police Court Proceedings.

The Motor-Vehicle and the Horse.—Before the Milverton Bench, on June 22nd, John Sharpe, Grosvenor Street, Coventry, and Frederick Henry de Veulle, engineer, of Coventry, were summoned by Alfred Shuttleworth, coachman, Kenilworth, for driving a light locomotive at Stoneleigh at a greater speed than 12 miles. Mr. Masser explained that complainant was a coachman in the employ of Mr. Charles Stringer, Park Hill, Kenilworth. On June 9th he was exercising one of his master's horses along the turf on the side of the road from Coventry to Kenilworth, when at the bottom of Burnt Post Hill, between there and Gibbet Hill, he heard the noise of a motor-car behind him, and the loud blowing of a horn. He looked round and saw a motor-car coming in the middle of the road at the rate of from 17 or 18 miles an hour. The horse became restive, and got into the road, while the motor-car came on, and ran into the horse's legs. The legs of the horse were badly injured, and the wheel of the motor-car was buckled. The horse succeeded in getting its legs out of the machine, and bolted, but was shortly afterwards pulled up by the complainant. Mr. Maddocks, in defence, dwelt upon the prejudice that existed against motor-cars, but urged they had as much right to the road as a horse, so long as they did not exceed the regulations. He pointed out that the complainant never raised his hand for the motor-car to stop, and that the horn was blown 60 or 70 yards before the motor-car came up, so that there was ample time for the rider of the horse to give warning if he wished to do so. As to the question of speed, he would like to know where it was that the motor-car was going too fast. Was it when 60 or 70 yards away from the horse, or at the time of impact? Had it been at the time of the impact the consequences must have been much more serious to the horse and to the persons on the car. As to anyone judging the pace of a machine coming on at a distance of 60 yards, it was absolutely ridiculous. After further evidence, the Bench decided that the car was going at more than 12 miles an hour. Defendant was fined £2, including costs. The case against Sharpe was withdrawn.

Not Proven.—William Brown, motor-car driver, and Richard Ashley, engineer, were charged, on June 25th, at Hamilton Police Court (Glasgow), with furiously driving a motor car, whereby it overturned on the Haughhead Brae, and nine persons were injured. On the motion of Mr. Miller, respondents' agent, trials were separated, and Ashley was placed at the bar. After evidence, Sheriff Davidson dismissed the case, holding that the accident was due to displacement of gearing, which, he suspected, was caused by excessive speed, but this had not been proved. The charge against Brown was withdrawn.

Driving Without a License.—At the Burgh Police Court (Dunoon) on June 22nd, Daniel MacPhun, motor-car proprietor, Sandbank, was charged with running a motor-car for hire between Dunoon and Sandbank on Thursday, June 16th, while the said car was not licensed for passengers by the magistrates, contrary to Section 272 of the Burgh Police (Scotland) Act. Objection was taken to the relevancy of the summons, and after Provost Doig and Mr. Cleery, the assessor, had retired to consider the point raised, it was intimated that in order to make the charge relevant, Section 270 of the Act should also have been quoted. The Burgh Prosecutor craved a case. At the Court held for the licensing of hackney carriages and stage coaches, MacPhun refused to accept his license because a condition was attached that he should not be allowed to run his car along Argyll Street but start from the Burgh Buildings. Thomas Wilkinson, the driver of the car, was fined *7s. 6d.* for driving without a license.

Not Guilty, yet has to pay Costs.—Before the Thorpe justices on June 20th, John Block, foreman fitter in the employ of the Motor-Van and Motor-Car Company, was summoned for illegally driving a motor-car at such a pace as to endanger the public safety, at Clacton-on-Sea. It was alleged that defendant drove the car round the corner of Pallister and Station Roads at a dangerous pace, knocking down a labourer named Chaplin, who was considerably bruised, and had to be medically attended. Defendant did not slacken the pace when rounding the corner. Mr. Prior, for the defence, contended that the man Chaplin stepped in the way of the vehicle, which was being driven by a skilful and experienced hand, at the rate of six miles an hour. Chaplin was in a dazed condition through drink, and it was due to his own negligence that he was injured. Having heard the evidence, the Bench dismissed the case on payment of the costs, £1 *0s. 6d.*

Alleged Furious Driving.—At the Southwark Police Court, on the 9th inst., Mr. Walter Charles Bersey, Manager of the London Electrical Cab Company (Limited), of Judson Street, Lambeth, was summoned before Mr. Fenwick to produce the driver of a motor-cab, numbered 17,070, to answer a charge of furious and wanton driving. Mr. H. E. Edmunds, solicitor to the Cabmen's Union, appeared on behalf of the driver, Charles Walter Evans, badge 31. Waterman, 291 M, gave evidence that just before midnight on the 20th of June the defendant Evans drove over London Bridge to the South Eastern Railway Station, and that he went up the railway approach at a rate of from 12 to 14 miles an hour. A man was nearly run over at the crossing, and the witness signalled the driver to stop, but he refused to do so until he returned from the station into the street. When told he would be reported he said the witness must be "hard up for a job." Mr. Fenwick adjourned the case for the attendance of a witness, but would first hear the defendant's witnesses, to save the expense of bringing them again. Thomas Nugent, instructor at the electrical yard, said it was impossible for the cab in question to go more than 8 miles an hour, and as a matter of fact it broke down on the return journey. Wm. Randall said it was the slowest cab out of the 16. The hearing was adjourned.

A Mischievous System of Business.—On the 6th inst., at Guildhall Police Court, before Mr. Alderman Alliston, Edward Alexander Bremner, 31, clerk, giving an address in Eaton Terrace, St. John's Wood, was charged with stealing cheques belonging to his employers, the Motor Manufacturing Company (Limited), Holborn Viaduct, to the amount of about £63, and forging them. It was stated that it was part of prisoner's duty to fill up cheques for signature. Those in respect of which he was charged were payable to Messrs. Robbins and Sons, of Bristol. It was alleged that he forged them and opened an account in the name of Robbins at the Bank of Great Britain, St. Andrew's Hill, giving a false address and a fictitious reference. Mr. Wilkinson, a clerk from the bank, said he believed inquiries were made in the usual way. The Alderman.—Yours is a most mischievous system of conducting business, and open to fraud. You allow this man to open an account with you without getting a proper reference or a proper address. After a short remand the prisoner was committed for trial.

Bankruptcy Court.

Re W. D. RAMSAY.—This was a sitting before Mr. Registrar Brougham, on June 24th, for public examination. The debtor, described as of Cornwall Road, Westbourne Park, stated that he was formerly an explorer, then a butcher, afterwards a hosier, and finally a general commission agent. For some years prior to 1877 he was prospecting and gold mining in New Zealand and Northern Queensland. In 1896 he formed a company, which was registered with a capital of £60,000, under the style of Ramsay's Horse, Carriage, Cycle, and Motor-Car Repository, but as only £350 was subscribed the company did not go to allotment. The accounts, recently filed, showed unsecured debts £683 10*s.*, and debts fully secured £2,000, with assets nil.—Further time being required by the Official

Receiver for the examination of the accounts, the examination was adjourned.

Re ALBERT SMITH.—A sitting of the London Bankruptcy Court was held on June 21st, before Mr. Registrar Linklater, for the public examination of Albert Smith, company promoter, 38 and 39, Parliament Street, Westminster. The accounts presented by the bankrupt show ranking liabilities, £1,194 4*s.*, and assets, "Cash, 12*s.* 11*d.*" Replying to Mr. Pope, the bankrupt said that in March, 1896, he assisted in the promotion of the Peerless Metal Company, and in addition to being appointed as secretary, he received £1,000 cash and £7,000 in shares for his services. He subsequently transferred all the shares to Mr. Wm. Mills, who had provided the funds for the flotation. Then, in June, 1897, they attempted to promote the Peerless Metal and Martino (Limited), the idea being to amalgamate the Peerless Metal Company with a Birmingham business carried on by Messrs. Martino and Son. That flotation fell through, the subscriptions being insufficient to justify proceeding to allotment. The examination was eventually ordered to be concluded.

NEW BATTERY FOR IGNITION AND SPARK COILS.

MESSRS. SHIPPEY BROTHERS, of 13, King Street, Cheapside, are placing on the market a "new type of copper oxide battery," which has been designed by Professor Gordon for oil and gas motor work. The outer jar is a "spun steel shell," enamelled by a special process and very light in weight. The motor-type measures 4½" × 6". The cell is fitted with a compound composition cover, making it nearly watertight, and being insulated from the generating elements by insulating washers fitted both above and below a metallic perforated cylinder which contains the copper element, and around which is placed a zinc cylinder, connection being made by a stout copper wire passing through an insulation bushing on the cover; the copper connection is made by a metal rod which suspends the perforated cylinder, which is furnished with a phosphor-bronze thumbscrew connector. The chief claims for the "Gordon Battery" are (1) long life; (2) high efficiency; (3) economy in cost; (4) absolutely non-freezing; (5) labour saving; (6) low internal resistance; (7) freedom from local action and freedom from gaseous odours. The construction of the cell is strong and simple, and it seems well adapted for its purpose. It furnishes a comparatively large current, which is nearly constant. It is claimed that its life is 120 ampère hours for one charge of the exciting materials, which consist of copper, zinc, and "electro sodium." A sample of this interesting cell has been submitted to us for inspection, and we shall report upon its capabilities in our next issue.

THE DUCHESSE D'UZÉS: THE FIRST "CHAUFFEUSE" IN FRANCE.

(From *La France Automobile.*)

THIS great lady, free from all those prejudices of caste which annihilate many qualifications and caprices, the Duchesse d'Uzés is a type very uncommon at our end of the century. She has passed before the Prefect of Police an examination which has made her the first *chauffeuse* in France, and that is a title which she has added to all those by which public attention already signalled her out. The heroines of Fronde that Cousin loved so much had not more courage than this good Frenchwoman, who undertakes all kinds of generous or benevolent works. And charity has not a more indefatigable zealot than this Parisian, whose hotel in the Avenue des Champs Elysées is known to all the unfortunate. And Diana herself was not fonder of hunting than this sportswoman, who perpetuated the complete traditions of hunting last year at the Castle of Bonelles. But she is, above all, an artist, for the pursuit of which neither politics, benevolence, nor sport has sufficient power to keep her during her moments of leisure; she writes, paints, sculptures, with an astonishing talent, under the pseudonym of "Manuela," and, in short, it is to these intellectual pursuits that this admirable *chauffeuse* adds the sweetest and less deceptive dreams.

Madame Anne de Rocheshouart Mortemart is a Parisian of Paris. From her father she inherits that old blue blood which, so says Xavier de Montépin, gave them the right to keep their heads covered in the presence of the King; on her mother's side she belongs to the rich commoners of Cliquot; she is also much interested in the poor through Louise Michel, who is her friend. At 19 she married the Duc Emanuel d'Uzés, who was a representative of the Assemblée Nationale, and who left her a widow at 30. Her eldest son, Duc Jacques d'Uzés, died several years ago in bravely exploring the Congo. She has another son, who is heir to the old de Crussol family, descendants of the notary Géraud Bastet, and two daughters, who are the wives of the Ducs de Luynes and do Brissac.

The Duchesse d'Uzés, interviewed by an editor of *Gil Blas* on the subject of automobile locomotion, is reported to say:—

"I am astonished to see the stir that has been made about this thing, which is so simple in itself. For more than six months I have been in possession of an automobile carriage, of which I will not mention the stamp, so that none can reproach me with pushing forward my builder, with whom I am quite content. Now, you know, one cannot conduct a vehicle to Paris without having passed a difficult examination; it is true that a large number of *chauffeuses* make game of the police arrangements, but they expose themselves

MADAME LA DUCHESSE D'UZÉS.

to disappointments that I should not care to incur. Allow me, moreover, to remark, in passing, that in spite of all, I shall not have the right to go out with my carriage for a fortnight, until I am in possession of the parchment authorising me to do so. What are my impressions, you ask me? They are delicious. At first it was the pace that pleased me, to pass quickly, quickly all other carriages sufficiently adroitly so as not to touch, then also the pleasure of being able to run along beautiful provincial roads, between avenues of trees of different perfumes which accord sensations calculated to give pleasure to artistic souls who adore nature. And I assure you that all these ideas gave me strength and the necessary coolness to carry through my examination, which seemed too short, much too short. In conclusion I tell you that my example will be followed, I am convinced, by the greater number of the aristocratic Parisian ladies."

We regret to add that this estimable lady has lately been fined for furious driving in Paris.

The Northumberland Agricultural Society's Show.—A parade of motor-vehicles took place at this Society's Show, held in Newcastle on the 13th, 14th, and 15th of this month. Messrs. Toward and Company's No. 1 steam-car, which ran at Liverpool, was present, as also were a steam delivery van and steam tractor by the same firm. Messrs. Atkinson and Philipson's No. 4 steam wagonette also took part, and one or two Daimler cars helped to make a fair show. We intend giving a full description of Messrs. Toward and Co.'s steam tractor in one of our early issues.

COUNTRY ROADS.*

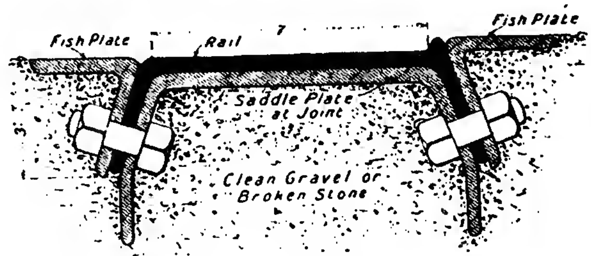
One class of work which promises to give an ever-widening field for the work and study of the engineer is that of improving the means of transportation in the country districts, and it is the object of this paper to review briefly some of the possible improvements. In the first place, the country roads demand attention. You are all, no doubt, well aware of the necessity for a general improvement in this direction, and those who have had personal experience in the matter are also aware of the difficulties encountered in getting such improvements started and carried out in a proper manner. These difficulties arise, to a great extent, from the cost of the proposed works. In fact, the "good roads" movement has suffered in some respects from too much zeal and enthusiasm on the part of many of its advocates, who insist upon a uniform standard of excellence and the highest class of construction, overlooking economic considerations and local conditions. Special emphasis has been laid upon the advantages of stone roads, and various arguments have been presented to show their advantages over other types of construction. Stone roads are excellent in their way and in their place, but there are many localities where the expense would be almost prohibitive, and would not be warranted by the amount of traffic to be accommodated.

It does not follow that good roads cannot be built in such places. Suppose yourself to be in charge of a district where a movement is started in favour of getting something better than the common country road, which is dirty in summer, muddy in the spring and autumn, and comfortably passable only when well paved with packed and frozen snow. Bearing in mind the traffic on the roads, you prepare plans for a system of stone roads, and also prepare a statement of the advantages of such roads, their durability, the easy traction over them, and the small expense required for maintenance. The local authorities, perhaps, simply refuse to consider any such proposition. They will not, and perhaps they cannot, find the means, and they may even hint that the proposition is unreasonable or impractical. You may be satisfied in your own mind that your arguments and estimates are well founded, but the fact remains that you cannot carry your plans into execution. Are you therefore to abandon your work on the ground that it is stone roads or nothing? Not at all, for here comes in that principle of economics which is at the base of many good engineering works, namely, "Do the best that can be done under the existing or limiting conditions."

You look around and consider the available materials, the traffic, and the expenditures which the authorities will be willing to make. Stone suitable for road work—and this does not include every kind of stone—may be obtainable only at a great distance and high cost. Furnace slag may be obtainable at less cost. Gravel of some kind may be near at hand, or clay suitable for burning. Perhaps you can afford to put up a plant to wash the gravel, and so get an excellent material. Or it may be that you cannot get, or afford to get, anything better than the dirt used on the roads whose condition it is desired to improve. Under any of these conditions the engineer will rise to the occasion, and if he cannot get what he considers the best material, he will do his best with such material as he can get. And it must be remembered that fairly good roads can be made with earth or dirt, if they are built with proper care, and then properly and continually maintained. If the farmers and country people in general could be roused to the extent of building good dirt roads, they would probably be surprised at the satisfactory results obtained at small expense. Ample drainage and careful maintenance are necessary, and where a district provides good dirt roads it will usually be found advantageous to employ specially instructed men to give regular attention to the maintenance of the roads.

This question of maintenance is one which must be taken into account with any character of road, no style of construction being sufficiently permanent to admit of its being left to take care of itself. Whether built of hard stone, soft dirt, or any intermediate character of material, it will eventually wear into ruts and holes, the time depending upon the quality of the material and construction and the amount of the traffic. When once such ruts or holes have been formed the deterioration of the road will proceed rapidly, unless repairs are promptly made. In reconstructing roads, improvements in the grades and alignment may often be introduced, as in railway reconstruction. The roads should be planned and laid out by an engineer, built by contract, or by day labour under the direct supervision of the engineer, and then cared for by a permanent gang of men properly instructed and employed solely for this purpose, under the direction of the engineer. The expense of such maintenance need not be great, and would result in continually keeping up much better roads than if the roads were left to wear out until they got in such condition as to make it necessary to dump cart-loads of dirt or gravel to fill holes and low spots.

The next consideration is the use of steel rails along the country roads to facilitate wagon traction and reduce the wear of the roads. Two different types of steel rail construction have been designed for this purpose; in the first the rails resemble rolled joists, with the top flange slightly concave, and in the second they are of inverted trough section. Both are merely theoretical as yet, though the trough rails are in experimental use. The H rails, as proposed, are about 4½ inches high and 3½ inches wide, weighing 24 lbs. per yard, and these would be connected at intervals by tie rods or bars to maintain the gauge. The cost is estimated at about 1,000 dollars —£200—per mile for the metal, exclusive of the macadam or gravel roadbed in which it is proposed to embed the rails. In the other plan the rails are inverted troughs, with a flat top and flat sides, a rib or bead along the outer side of the top serving to guide the wheels. The joints are of special form, with inside saddles and outside splice bars having their ends inclined so as to bring wheels upon the rails. The light type will require about 50 tons of metal, and cost 1,000 dollars—£200—per mile; the heavier 2,000 dollars to 3,500 dollars—£400 to £700—per mile. In addition to this there is the cost of grading and track laying. A short stretch of track of this kind was laid in 1896 in a dirt road near Joliet, with 4 inches of gravel between the rails, and this has lasted well under heavy traffic, including traction engines. Travel on this was easy at a time when other roads were almost impassable.



Very high claims have been made for reduction of traction and increase of loads with such track, but it is not safe to estimate on more than double the load which a horse can draw on fairly good macadam, or perhaps three times the load on a fairly level road. The character of the traffic must of course be taken into account, the advantages of such a trackway being most evident where the road has a continued and heavy traffic. It is questioned also whether it would have any special advantages over a well-built macadam road, except where specially heavy hauling is done, or where the gravel or stone wears out rapidly. It is evident that a good foundation must be provided to keep the rails in proper surface, and the heaving of the ground by frost must be taken into consideration.

In this connection reference may be made to the plan tried near Monmouth, of laying a strip of brick paving on a dirt road. The paving is a single course of brick, 7 feet wide, on 6 inches of sand, held in place by wooden curbs and stakes, while on each side of the paving is about 30 inches of the broken limestone used for macadam roads in that district, harder stone not being available. The cost was about £800 per mile, as compared with £740 for macadam 9 feet wide. In view of the easier traction on the brick, it has been suggested that a still cheaper arrangement could be made by laying two brick trackways 20 inches wide and 3 feet 6 inches apart, embedded in 8 inches of macadam. Either of these systems is applicable to suburban as well as country roads.

So far the subjects considered have referred only to means for improving the ordinary methods of transportation by wagons and carriages; this, however, is not the limit of possibilities in the improvement of transportation.

In many localities there exist some special traffic which may be developed by improved transportation, and, if private interests take up such a matter, the engineer may be called in to advise upon the

* Excerpt of a paper read by Mr. E. E. Russell Tratman, C.E., at the annual meeting of the Illinois Society of Engineers and Surveyors held at Peoria, U.S.A.

best means of transportation. Such special traffic may come from mills, factories, large farms, &c., and the provision for this traffic will include provision for the general local traffic of the district, which, while unimportant in itself, may form a valuable addition to the general receipts. In suburban and country districts, where there is considerable passenger traffic, this may be developed by means of regular lines of omnibuses or motor-carriages operated by steam, oil, or electricity, running between different towns and villages and neighbouring railway stations. In other districts a heavy traffic in raw material and manufactured or agricultural products may be greatly facilitated and economically handled by means of traction engines. Neither of these methods of transportation, however, has as yet received much attention in this country, at least for general traffic purposes, owing largely to the average poor condition of our roads.

The next step to which reference will be made is that of building a railway or a tramway. The former has the smaller scope for developing the purely local traffic of a country district, and is not in general a safe thing for small interests to handle. It is apt to be an uneconomical investment if operated in the usual manner with an infrequent service of ordinary locomotives hauling trains of cars. On country branches or feeder lines, however, a step towards greater economy and efficiency may be made by introducing light steam-cars, with engine and car combined, and giving a better and more liberal service.

The character of line which is specially adapted to the requirements of the freight and passenger traffic of a country district is the tramway, following the main road in general, but cutting across country when desirable, and stopping at any house, farm, factory, or road-crossing to take up or set down passengers, parcels, and general freight. The capabilities of such a line are almost unlimited. Lines of this character are already very numerous and their number is steadily increasing. With this increase comes an improvement in the construction and equipment, due partly to the requirements for increased speed. By far the majority of such lines are operated by electricity on the overhead wire system, but independent motor-cars, operated by steam, compressed air, gas, oil, or storage batteries, or a combination of these, are in use to some extent and have the advantage of requiring no power plant, except for compressed air and batteries, though the latter may be charged at some existing station.

Where the line is built upon the highway it is essential that the rails should offer as little obstruction as possible to the wheels of ordinary vehicles, while at the same time sufficient clearance must be left for the flanges of the wheels. The rails may be of the regular flange or railway section, or of girder section, from 56 lbs. to 85 lbs. per yard, but the tendency is to use heavier rails than those used on steam railways in proportion to the weight of rolling stock and amount of traffic. On many of the smaller lines the cars are small and light, carried on four wheels, but on lines with heavy traffic and high speeds there are large cars with four-wheel bogie trucks. With the high speeds employed on some of these lines special care must be given to the sharp curves which are often necessary, and on one line a right angle curve of 40 feet radius has the ends eased off to 200 feet radius at the tangent points, the transition being made in a distance of 15 feet.

In laying out a line of this character attention should be given to the possibility of improving the grades and curves of the highway during the construction of the line, and also to the possibility of avoiding circuitous routes and bad grades by buying right of way on an improved location, taking care not to lose chances of local traffic merely to shorten the route. Bridges and viaducts will often be required, and may be of wood or steel according to the location and the cost, but care should be taken to have thoroughly safe and substantial structures.

A New Club.—As will be seen from an announcement we make elsewhere, a new Club is in process of formation in South London for, *inter alia*, the discussion of subjects relating to automobilism. A strong committee has been formed, and we understand that numerous applications for membership are coming in. As its name indicates, the Club is mainly composed of foremen engineers, draftsmen, and others engaged in the actual construction and working of motor-vehicles. Such a Club will be able to do a great deal of good in perfecting designs and popularising the movement. At present it is in able hands and we wish it every success.

OBITUARY.

MR. JOHN PHILIPSON.

WE regret to record the death of this eminent coachbuilder, which took place on the 24th ult., at his residence in Newcastle-on-Tyne. The deceased gentleman was the senior partner in the firm of Atkinson and Philipson, Newcastle, one of the most important firms of carriage builders in Great Britain. Mr. Philipson was born in Newcastle in 1832, and was educated locally. He was apprenticed to his father and served his time at the bench as a practical body and carriage maker, going for further experience to London, to the firm of Messrs. Briggs and Co. About 30 years ago he succeeded his father, George Hare Philipson, J.P., in the business. During a remarkably active life he was associated with the principal literary and scientific societies in the North of England. As an inventor he added in a practical manner to improved construction, and his services were in constant demand at several international exhibitions. He was made an honorary member of the Carriage Builders' National Association, and was nominated as President of the Institute of British Carriage Manufacturers for the year 1895. He worked very hard and indefatigably to secure the abolition of the carriage tax. His efforts were highly appreciated by everybody connected with the coach-building industry, and on January 22nd, 1891, his labours in this direction were recognised in a handsome illuminated address, which at that time was presented to him by his friends. The address was accompanied by a cheque. The presentation was made at the annual meeting of the Institute of British Carriage Manufacturers, at the Hall, Baker Street, London. Mr. Edward Rogers, of Bristol, was in the chair. The address stated that the testimonial had been subscribed by representatives of the British carriage-building industry and its accessory trades, "as a mark of our appreciation of your exertions in promoting the interests of the industry in the matter of the repeal of the carriage tax, and which, although not entirely successful in obtaining the total repeal of the tax, have contributed largely to secure the important modifications which have been obtained." The address proceeded: "The agitation of the repeal of the tax, which commenced upwards of 40 years ago in your own city of Newcastle, has at your hands, by the energy and impetus you have given to the movement, and by your large expenditure of time and money in promoting the work, been brought, in its entirety, nearly to a successful issue."

Mr. Philipson was a J.P. for Newcastle, and much esteemed as a magistrate. He leaves a large circle of friends to mourn his loss. We might mention, in conclusion, that the deceased gentleman took a great interest in automobilism; and, although not believing in the total suppression of the horse, he recognised that for, at any rate, purely commercial purposes, the motor-vehicle would surely displace the horse-drawn one.

NOTES OF THE MONTH.

AN interesting series of articles on the petroleum industry is appearing in *Knowledge*, from the peu of Mr. Geo. T. Holloway, F.I.C.

M. ALEX. T. HOLLINGSWORTH, the managing director of *Engineering*, has joined the board of Weldon's (Limited), the well-known proprietors of various journals devoted to female interests.

IT is stated that a contract has been given to the Gloucester Railway Carriage and Wagon Company (Limited), by the London Electrical Cab Company (Limited), of Lambeth, for the building of a number of their cabs.

The Deutsche Gold and Silberscheide Anstalt of Frankfort-am-Main, in conjunction with Messrs. Brown, Boveri, and Co., of Baden, are reported to have decided on the construction of large works in Germany for the production of calcium carbide.

THE *Machinery Market* contains in its July number not only an excellent article on the acetylene gas industry, but also gives an equally excellent plate photograph and biography of Professor V. Lewes, R.N., the well known chemist, and the introducer of calcium carbide to this country. Professor Lewes may, with strict truth, be regarded as the father of the industry.

SOME coal cars, each capable of holding 80,000 lbs. (about 36 tons), have recently been built for the Illinois Central Railroad. Each car measures 38 feet 6 inches over end sills, its inside dimensions being 35′ 7″ × 9′ 4″ × 3′ 6½″ high. It runs on two four-wheel bogies, the wheels being 33 inches in diameter, whilst the axle journals are 5 inches in diameter by 9 inches long.

THE *Austral Wheel* for May contains an account of a remarkable motor-cycle owned by Messrs. Suttou Brothers, and which "has just accomplished 400 miles on four gallons of oil." We should like to see that motor. According to the best French practice, the consumption of spirit (gasoline, petrol, or naphtha) is about ·8 pint per mile, and hence a run of 400 miles would require at least 40 gallons.

MR. WALTER C. BERSEY was married to Miss Christina Mackenzie on the 6th inst., at South Hackney Church. After the ceremony the guests were conveyed in about 25 electric cabs to the Hotel Cecil for refreshments and the reception. The bride and bridegroom, however, preferred the ordinary pair-horse brougham. Needless to say the occasion was quite a gala day for South Hackney.

WE notice that the Yarmouth fly-drivers are making energetic but futile efforts to prevent the encroachment of the motor-vehicle upon what they consider their own preserves; as "heavy ratepayers and large employers of labour," they, of course, want to stifle all competition, and allege all sorts of dangers as likely to arise if the hated motor-vehicle is permitted to ply for hire in that select paradise of the cheap tripper.

THE first motor-vehicle mail service between different towns was started in Scotland in the middle of last month. A motor-vehicle has been substituted for a mail-gig between Inveraray, the county town of Argyllshire, and Ardrishaig, a flourishing township on Loch Fyne, at the entrance to the Crinan Canal. The distance between the places is about 25 miles, and there are four postal hamlets to call at on the way. The vehicle travels at the rate of 10 miles au hour.

THE largest locomotive in the world is, observes M. Henri de Parville, the "Giant," of French type, on the Mallet compound articulated system, that was constructed by the Belgian State Railway Administration for the sharp gradients near Liége, having been shown at the Brussels Exhibition of last year. This engine, carried by six pairs of wheels, weighs in running order 108,000 kilos. = 106 tons, which weight is entirely utilised for adhesion; but the arrangement is such that each pair of wheels only loads the rails with 18,000 kilos. = 17¾ tons.

THE Londou Road Car Company have placed upon the route from Hammersmith to King's Cross a new omuibus with wheels which have been fitted with roller bearings, as supplied by the Roller Bearings Company, of Westminster. The hubs are of iron, into the sockets of which wooden spokes are driven, and the bearings, consisting of a series of steel rollers controlled and prevented from cross winding by a bronze cage, enable the car to be moved easily by one man. A uoticeable feature of bearings of this class is the great reductiou effected on the starting resistance, an important matter in an omnibus or tramcar.

THE motor-vehicle is sufficiently an article of public convenience to be recognised by dramatists. Lately, at a certain transpontine theatre well known for its powerful and thrilling tragedies, the villain, instead of "dissembling" in the orthodox way and escapiug in his victim's carriage, brings on his own motor-vehicle, which he conveniently keeps in the back garden. After accomplishing his fell designs against the virtuous daughter of his benefactor, he escapes on his motor-car. Recently, too, in Paris at the Varieties a real motor was driven round the stage in the "Tour du Bois," and amidst great applause.

THE noise and also the disagreeable odour of gas and petroleum engines have, it is reported, been suppressed in a very satisfactory degree by M. Chevalet, who places inside of, or on the top of, the cast-iron chamber in which the products of the explosion are generally received a few scrubber rings, such as are used in gasworks. A considerable diminutiou of the noise was effected by a scrubber 40 cm. (15¾ inches) diameter placed over a 3½ H.P. petroleum-engine, and also upon a 1 H.P. gas-engine. With the latter class of motors it is not necessary to sprinkle with oil the shavings ou the plates of the scrubber, but with a petroleum-engine this precaution should be taken. Disagreeable odour is thus almost completely suppressed, if a naturally inodorous oil be used for the sprinkling; and this oil may serve for lubrication, after having been freed, by settlement or decantation or by filtering, from the solid matter which it may have drawn along when traversing the plates and shavings of the scrubber, &c.

CYCLING as a "sport" is exhausted and ceases to attract, for the simple reason that a bent-backed man clothed iu curious garb running round and round on a track is uot of itself an exciting thing, neither does it prove anything of use. It moreover encourages a low class of gambling. Still, those who are interested in promoting "contests"—races, records, and other childish delights, dear to the heart of the average cyclist, cannot afford to see their "sport," as they call it, languish, and so they have hit upon a novel and distinctly elevating source of attraction, viz., the slaughtering of live oxen in the "grounds." Thus, at a recent cycle meet at Wood Green, two professional gentlemen, Messrs. Paul Tetzel, of Chicago, and Edward Harper, of London, competed for the international beef-dressing championship aud £400. Over 2,000 spectators witnessed the contest. The American proved the winuer, dressing a couple of bullocks, fit to be placed on the market, in 18 m. 33 s. Harper occupied 22 m. 22 s. to do the same amount of work. We shall now have to keep note of our kindred sport of beef-dressing. This exhilarating pastime, says the *Scottish Wheel*, cau be cordially recommended to the notice of our cycling clubs who wish to introduce novel features into their club fixtures.

IT is, however, satisfactory to note that this disgusting, brutalising, and outrageous spectacle is not likely to be repeated, as it is in itself illegal. But to think that at the end of this nineteenth century such an exhibition should be possible in order to attract visitors to a cycle show is in itself striking evidence of the innate brutality of the mob. We wax virtuously indignant at the horrors of the Spanish bull ring and the callousness of the Latin people to animal suffering, but are these latter any worse than those "2,000 spectators" at Wood Green who witnessed the slaughtering contest?

WALSALL is an interesting town, the inhabitants whereof are much addicted to the manufacture of saddlery and other things used by horses. It rejoices, or rather did, in being represented in Parliament by Mr. Sydney Gedge, a shining light of no mean order. Mr. Gedge, as befits one in his position who has been converted from the worship of the horse to that other belief which sees commercial salvation for the country in the motor-vehicle, naturally is zealous on behalf of the latter, and so presided at the lunch given by Mr. H. J. Lawson lately at the Whitehall Rooms. Walsall is indignant and sorrowful; its confidence has been abused. It is not as though an enemy had done this thing, but their own guide, their own familiar friend and representative, to thus in effect depreciate a native industry and help on the cause of automobilism is too bad. The outraged feeling of the free and independent voters of Walsall is finding free expression in the local Press.

As many inquiries reach us as to the price of petroleum, we give the following quotations recently received by the London County Council from various firms. The Council specified for the supply of petroleum illuminating oil having a flash point of not less than 105° F. (Abel test):—Middleton Bros., 3⅝*d.* and 5⅛*d.* a gallon; Anglo-Caucasian Oil Company (Limited), 3⅞*d.* a gallon; Young's Paraffin Light and Mineral Oil Company (Limited), 4½*d.* a gallon; Mineral Oils Corporations (Limited), 4½*d.* a gallon; Pinchin, Johnson, and Co., 5*d.* a gallon; T. Walton and Co., 5¼*d.* a gallon; J. F. Percival and the Kerosene Company (Limited), 5⅜*d.* a gallon; Livett Frank and Son, 5½*d.* a gallon; and R. W. Medhurst, 7½*d.* a gallon. The chemist of the Council who examined the samples submitted with the tenders, reported that the sample of the oil sent in by Young's Paraffin Light and Mineral Oil Company (Limited) had a flashing point of 128° F. (Abel test), and that the oil appeared to be the safest of those offered to the Council. The lower priced samples did not possess the flashing point stipulated for. Under these circumstances the tender of Young's Paraffin Light and Mineral Oil Company (Limited), for the supply of petroleum oil at 4½*d.* a gallon for one year from July 1st, 1898, to June 30th, 1899, was accepted.

Worm-gearing for Electrical Motor-Vehicles.—The advantages claimed for worm-gearing, as opposed to spur-gearing, are:—(1) That the former allows the use of high-speed, and therefore lighter and cheaper, motors; (2) the motor can be at a distance from its driven axle, on which only the weight of the worm and gear need bear directly; in the case of a double truck, the motor driving one axle can be supported on springs over the other axle; (3) the saving in cost on the smaller motor would allow of wrought-iron magnets and laminated pole-pieces, thus increasing the torque; (4) greater clearance can be obtained between the motor and the road-bed; (5) since worm-gearing is not a reversible combination, it forms an efficient brake when current is cut off; (6) repairs to small motors are easier and cheaper. The one disadvantage noticed is that a disabled car cannot be towed without detaching the worm-gear. The author suggests rolling friction as a possible improvement in worm-gearing, and predicts that double-reduction gearing, which superseded the more efficient single-reduction gearing, will in turn give place to worm-gearing, the loss in efficiency being outweighed in both cases by advantages gained in other respects.—*Science Abstracts.*

THE AUTOMOBILE CLUB OF GREAT BRITAIN.

THE Automobile Club of Great Britain has been very busy since our last issue. Many of its members who are specially interested in the automobile movement visited the Paris Automobile Exhibition in the middle of June. Mr. Frederick R. Simms was very energetic in forming this party, which included, amongst others, the Chairman (Mr. Roger Wallace, Q.C.), Mr. Frank Butler (Hon. Treasurer), Mr. Alfred Bird, Mr. Worby Beaumont, Mr. P. Drummond (of Stirling), Mr. Herbert Capel, Mr. J. H. Knight, Mr. E. Townsend, Mr. C. Twist, Mr. A. L. White, Mr. A. Mulliner, Capt. Sampson, J.P., Mr. Lyons Sampson, and the Secretary (Mr. C. Johnson).

The President of the French Club was so good as to make these gentlemen honorary members of the Automobile Club de France during their sojourn in Paris. Nothing could be more delightful, after a day's hard work examining the Exhibition, than to take the Club motor omnibus to the villa of the Club in the Bois de Boulogne and to dine under the trees there.

The run of the Automobile Club to Virginia Water was a great success (except as regards the dinner itself). The Club ran three motor-wagonettes for its members. These were supplied by the Daimler Company.

(1) Club wagonette No. I, driven by Mr. A. H. D. Altree. Passengers: Mr. and Mrs. Lyons Sampson and friend, Mr. and Mrs. Worby Beaumont, and Mr. and Mrs. Staplee Firth.
(2) Club wagonette No. II, driven by Mr. E. M. C. Instone. Passengers: Sir John Leng, M.P., Lady Leng, Mr. and Mrs. T. Bousquet Browne, and the Secretary.
(3) Club wagonette No. III, driven by G. R. Sewell. Passengers Sir J. R. Somers Vine, C.M.G., Mr. H. Somers Vine, Mr. Berger Graham, Mr. Alfred Thompson, Mr. Leonard, Mr. H. P. Wolff.

There were the following carriages also:—

(4) Britannia electric carriage (the Honourable J. H. H. Berkeley).
(5) Britannia electric carriage, No. 2.
(6) Benz, $2\frac{9}{10}$ H.P. (Mr. Frank Butler).
(7) De Dion tricycle (Mr. R. Phillips).
(8) Benz Ideal (Mr. H. Hewetson).
(9) Benz, $2\frac{9}{10}$ H.P. (Mr. W. P. C. Wills).
(10) Arnold (Mr. R. W. Buttemer).
(11) Daimler Victoria (Mr. C. Cordingley).

Considerable astonishment was created at Henley by the sight of the motor-carriages of the Automobile Club standing close to the water's edge on the lawn specially reserved for the Club close to the enclosures of the Sports Club, Bath Club, &c.

Some of the carriages drove from London to Henley and back in the day, and their occupants sat comfortably in them and viewed the racing. At the back of the enclosure there was an excellent Club tent in which luncheons, &c., were served to members and their friends on the three days of the regatta. One Henley is so like another that *habitués* are ever on the look out for novelties. The Automobile Club enclosure was the novelty of the regatta, and as such excited much comment and interest; but it was remarkable to notice that, whereas a few months ago motor-vehicles were treated with scorn and contempt, they were at Henley the cause of serious examination and polite inquiry.

Mr. Lyons Sampson had invited a few other members of the Automobile Club to drive with him to Hurlingham. It was somewhat of a departure to see the occupants of the carriage dressed in top hats, frock-coats, &c. However, they certainly looked smart, and demonstrated the fact that a yachting costume is not indispensable to carriage exercise, because there are no horses attached to the vehicle. The authorities of Hurlingham on this occasion gave the motor-wagonette a place next to the coaches.

Mr. Herbert de Stern (who has recently been elected a member of the Automobile Club) has just given a large garden party at the historic Strawberry Hill House, which is now his property. He drove down on a Daimler, and from eight to ten owner-members of the Automobile Club drove their motors to his party.

The Committee of Sandown Park Racecourse have reserved an enclosure for the Automobile Club for the Eclipse Stakes meeting on the 15th and 16th inst.

Perhaps one of the most enjoyable functions of the season in connection with British automobilism will be the entertainment which Mr. Frank Butler (the Honorary Treasurer) is giving to the Automobile Club at his well-known house boat, the "Dolce far Niente," at Shiplake, on the 23rd inst. Mr. Butler has asked a large and distinguished company to meet the Club. A marquee is to be erected on the meadow behind Mr. Butler's houseboat, and over 300 guests have been invited to luncheon. Signor Bocchi's orchestra will be present.

Some of the members will stay at Henley on the night of the 23rd inst., and will run from Henley to Oxford and back on the 24th, and to London on the 25th.

Preparations are in progress for the Club Tour to South Hants and Cowes Regatta. We are asked to request members who wish to join in this tour to communicate with the Secretary.

Among the recent candidates for membership of the Automobile Club are Mr. Henry Edmunds (St. Stephen's and Whitehall Clubs), Mr. Harold Wade (Sports Club), Mr. G. A. Schenley (R. Yacht Squadron), Mr. W. A. Smith (National Liberal Club), Mr. Francis H. Medhurst, B.Sc. (St. Stephen's Club), Mr. W. E. Hipkins (Derby Club, Derby), Mr. Roland Browne (Devonshire Club), Mr. J. A. Holder (Conservative Club, Birmingham), who has just acquired an 8 H.P. Daimler carriage.

DIARY OF THE FORTHCOMING ARRANGEMENTS OF THE AUTOMOBILE CLUB OF GREAT BRITAIN.

Friday, July 15th, and Saturday, 16th. Run to Sandown Park Races and back for Eclipse Stakes.—An enclosure to contain six motor-carriages will be set aside on the racecourse for the Automobile Club.

Saturday, July 23rd. Run to Shiplake. Luncheon by invitation at Mr. Frank Butler's houseboat. Supper at Henley. Sleep at Henley.

Tour to Henley and Oxford.—Saturday, July 23rd, Sunday, 24th, and Monday, 25th.

Club wagonettes and private motor-vehicles which have not proceeded to Henley earlier in the day in answer to Mr. Butler's invitation, will leave the Club on Saturday, July 23rd, at 3 p.m., and will proceed *viâ* the Bath Road, Twyford, Wargrave, to Henley. Supper will be served at Henley at 9.30 p.m. The Saturday nights and the Sunday nights will be spent at Henley. On Sunday, July 24th, there will be a circular tour to Oxford and back. The start will take place at 10.30 a.m., and the route to Oxford will be *viâ* Nettlebed (4¾), Shillingford, Dorchester (14), Sandford, Iffley, to Oxford (23¼ miles). Luncheon will be served at Oxford at 1 o'clock. The start on the return journey will be made at 4 o'clock, and will be *viâ* Abingdon (6½), Stevenon (12¼), Blewbury (16¾), Streetly (22), Pangbourne (26), Reading (32), Twyford (37), Henley (41¾). Supper at Henley at 9 p.m. on Sunday night.

Monday, July 25th. Return to London. NOTE.—One of the Club wagonettes will leave Henley at 7 a.m., so as to land members in London between 10 and 11 on Monday morning.

August Tour. Cowes Regatta.—Saturday, July 30th, to Wednesday, August 3rd, or Thursday, 4th.

It is proposed to start from the Club on Saturday, July 30th, at 11 a.m., for Guildford (29¾) miles, Farnham (30¾), Alton (50). Sleep at "Swan Hotel," Alton.

Sunday, July 31st. Alton to Portsmouth (31 miles). Sleep at Southampton.

Monday, August 1st. (Bank Holiday). Club launch will run to witness the Royal London Yacht Club Regatta at Cowes. Sleep at Southampton.

Tuesday, August 2nd. Club launch will run to witness the Royal Yacht Squadron Regatta at Cowes. Sleep at Southampton.

Wednesday, August 3rd. Start back for London.

Thursday, August 4th. Complete journey for London.

(*The return journey may be commenced on Tuesday, August 2nd.*)

REVIEWS OF BOOKS.

"Les Automobiles sur Rails." Par G. DUMONT, Ingénieur des Arts et Manufactures. (Paris: Gauthier-Villars et fils, Quai des Grands Augustins, 55, 1898).

THIS work gives a quasi-technical account of that branch of automobilism covered by its title, but, having regard to the already extensive literature on the subject, and also to what we may term the inceptive development of automobilism, we question whether any useful purpose is served by describing systems of traction, many of which in the course of a few years will be relegated to the category of vain efforts. At the same time M. Dumont has done his work well within the limits at his disposal. He does not tell us much that is fresh, but his explanations are to the point. He describes nearly all the existing systems, but not with sufficient detail to be of value to the designer. The illustrations are on too small a scale to be of any use—a common defect in French technical literature. There are some useful tables giving attained results in various systems. As a record of street railway work in Europe the book has some value, but more than this we cannot say.

"Electro Dynamics: The Direct Current Motor." By CHARLES ASHLEY CARUS-WILSON, M.A. Cantab., M.I.E.E. (Longmans, Green, and Co., 39, Paternoster Row, London, 1898.) Price 7*s*. 6*d*.

IT is rarely one comes across an author who, so to speak, plunges at once into his subject. Usually, and especially so where electricity is the subject, a lot of orthodox and elementary matter is prefixed, and the advanced student is carefully taken through the interesting but somewhat jejune experiments associated with the logs of a dead frog or the skin of a defunct cat, in order to impress upon him the difference between static and voltaic conditions of electricity.

Professor Carus-Wilson, without assuming that his reader is, like himself, an expert in the higher branches of applied electricity, nevertheless requires a rather extensive knowledge on the part of those who would benefit by his teaching, and we rather question whether it is wise to take so much for granted. Thus, not a few students will find some difficulty, we should think, in grasping at once the full significance of the "induction factor" of a dynamo—not that we object to the use of this new term, but its precipitation upon one is somewhat sudden. It is, however, after all, an obvious term in dynamo design; it is an important factor; it represents the product of the number of surface conductors of the armature, the number of polar divisions of the latter, and the number of useful lines per pole, divided by the number of units in 1 volt. Further on this is defined as the induced volts by the revolutions per second of the armature. By varying the current in the magnets different values of the induction factor are obtained, and if those be plotted on a sheet of squared paper the "induction curve" is obtained, and if the ordinates of this be multiplied by revolutions per second we get the well-known "characteristic" curve. This first chapter is decidedly, at least to us, novel. It is followed by one in which the conditions for uniform motion are discussed. Hysterisis is defined as an expenditure of energy in the form of work—also to us a new definition, but we see no reason to question the reasoning by which the Professor reaches this conclusion. The torque on a motor-shaft is shown to consist of five elements, including hysterisis. In Chapter III the various equations of the induction factor for various specified conditions that obtain in practice are discussed, and we then come to the discussion of shunt and series wound motors. Here the student will find a mass of accurate information of an exceedingly instructive and valuable kind. The method of utilising two motors connected by a differential gearing, so that by varying the induction factor of them both inversely motion to a shaft is imparted, strikes us as exceedingly good and having wide possibilities. We are not surprised to learn that a German firm has already applied it.

The different methods of connecting motors are described, and many practical lessons deduced. Perhaps one of the most important conclusions reached is that series-connected motors for railway work are objectionable unless the driving wheels are coupled by connecting-rods. Considerations of space forbid us to notice the remaining chapters on "Efficiency," "Control," "The Force Factor." We can, however, especially commend that one on "Acceleration." This difficult subject is most admirably treated, and the same remark applies to the chapters on "Time Curves" and "The Design of Railway Motors."

We have read this work with advantage. Its great merits are that it puts electric traction in its most recent developments before the student, not alone in the theoretical aspect, but chiefly and mainly in its practical application. Indeed, it is a mistake to speak of this work as a theoretical treatise. As we have said, the Professor supposes that his readers have a fairly good mathematical training. Such will have no difficulty in following him. His style is by no means that of the teacher, but he remembers the weaknesses of students, and important deductions are printed in heavier type. Perhaps to many the most valuable feature of the work is the plethora of examples taken from actual and recent practice. After studying this work we feel that electric traction, unlike steamship propulsion, admits of very accurate determination—a comforting reflection for shareholders. It is undoubtedly the best book we know of on the subject.

"Science Abstracts." (London: Taylor and Francis, Red Lion Court, Fleet Street, 1898.) Price 3*s.* each.

SUCH is the rapid advance of scientific research that it is difficult for a busy man engaged in technical work to keep himself posted up in what is being done in other fields. Most men who endeavour to do conscientiously find that they have to subscribe to numerous technical journals and to belong to one or more scientific societies, in order to obtain a sufficiency of technical literature for their own private consumption. Although there is a vast quantity of matter dealing with scientific research published every week, yet much of it is mere literary embellishment or "padding" out of which one, often with difficulty, extracts the facts. It was, therefore, a happy thought to appoint a body of physicists engaged in various branches of pure and applied science and to entrust them with the task of wading through this mass of literature, and, to use a newspaper phrase, "boil it down" and presenting it to the scientific public in the shape of extracts. This has been undertaken by the Councils of the Institution of Electrical Engineers and the Physical Society respectively. The "abstractors" comprise many of the best known men in the physical world, and they have as editor Mr. J. Swinburne. The scientific public has thus every guarantee that the work is well done. The first number was issued in January, and the high level of general excellence then exhibited has been well maintained in each succeeding issue; the publication is, we should say, a monthly one. Physics, of course, covers a large number of sciences; in other words, it means natural philosophy. It will thus be seen that these abstracts appeal to a very large body of readers and workers. We ourselves find them very useful, and can recommend them to all who have not much time to spend in reading or studying. To students they will be especially useful. The price is, however, somewhat high, but this no doubt will be reduced as the sale increases. We welcome this new contribution to scientific literature, and trust it may have a prosperous career.

"The People's Guide to the Workman's Compensation Act." By R. M. MINTON-SENHOUSE, Barrister-at-Law, and G. F. EMERY, L.L.M., Barrister-at-Law. (London: Bemrose and Sons (Limited), Old Bailey.) Price 1*d.*

VARIOUS opinions obtain as to the necessity and effect of this Act, but that it is one in which working men—using this much-abused word in its ordinary restrictive meaning—are vitally interested is beyond question. Perhaps it is for that reason that probably not one "working man" out of a thousand understands any more about it than that it increases the employers' liability in some vague and undefined way. No excuse can now be made for any workman not understanding what the State has done for him by this Compensation Act. For the sum of one penny we have here a plain exposition of the Act divested of legal technicalities and well indexed. By the aid of this tiny work one can tell at a glance whether any stated employment is covered by the Act, but we should not advise any one to take the Act too literally, as until its intention has been interpreted by the judges—and most of our modern legislation is unintelligible until it has gone through this judicial ordeal—the framers of Acts not always knowing what they do mean—it will be well to hesitate. We may expect that the litigation arising out of this Act will be pretty extensive, so would-be litigants will not have to wait very long. In the meantime they can study this pennyworth of legal lore with advantage and let us hope with profit.

"Acetylene Gas and Calcium Carbide." By G. F. THOMPSON, Consulting Engineer. (Liverpool, Sixteth Street; London, E. and F. N. Spon (Limited): 1898.) Price 3*s.* 6*d.*

THE author of this work is a well-known expert in many branches of engineering and his description of acetylene gas, its manufacture, application, &c., may be taken as bringing our knowledge up to date and also as possessing the great merit of being authoritative. That this new illuminant, or, rather, that this new compound, calcium carbide, has a very great future before it is unquestionable. Acetylene is not, we think, likely to supersede gas or electricity in towns, but in isolated positions, such as country houses, lighthouses, ships, and lightships, especially the latter, its adoption to every other form of illumination is merely, allowing even for the Chinese-like conservatism of the authorities, a question of a few years. Mr. Thompson's book will do much to extend the use of this gas. He describes the process of its manufacture and its use in plain but not too technical language, and also the various systems of generators employed. Those whose business it is to keep themselves *au fait* with developments in lighting may not find much in this work that they did not know, but the lay reader who is desirous of learning "all about" acetylene cannot do better than read Mr. Thompson's excellent little work, which we trust will have a large circulation. With acetylene as with so many other products in their early applications, there is a good deal of prejudice on the part of the public to remove. Mr. Thompson clearly shows how this gas may be used with absolute safety provided ordinary common sense is employed, which, needless to say, is not always the case. After using coal gas as an illuminant for nearly a century, have we not the housemaid who *will* seek for a leak with a lighted taper, and can we expect that this always interesting, though at times trying, domestic will exercise greater intelligence with acetylene? She may—if the School Board will include Mr. Thompson's book in their curriculum, in which science in a very mild but very popular form is rendered easy of assimilation by the rising generation.

"Carnet du Chauffeur pour 1898." Par LE COMTE DE LA VILLETTE. (Paris: Rebierre et fils, éditeurs, 15, Rue Grenier, Saint-Lazare, 1898).

THIS is an automobilist's pocket-book which will no doubt appeal to the amateur a good deal more than it does to the professional engineer. It is dedicated to the members of the Automobile Club of France, of which body the author is technical secretary. There is a calendar giving times of rising and setting of sun and moon, with other astronomical information. We trust we shall not be hurting any one's feelings if we say that the insertion of ecclesiastical data in an automobilist's calendar strikes us as rather incongruous. The calendar is followed by a number of log sheets; then comes a table of octroi duties, and a list of depôts throughout France where petrol can be obtained. There is also a list of constructors, police regulations, hints for automobilists on repairs, &c. The principal vehicles are described and instructions given for working them. With the reservation above, we have nothing but praise for this useful handbook, and compliment its author on its, if somewhat tardy, appearance.

"Lubricants, Oils, and Greases." By ILTYD I. REDWOOD. (New York: Spon and Chamberlain; London: E. and F. W. Spon, 1898.) Price 4*s.* 6*d.*

WITH the more scientific treatment of machinery, with the idea of obtaining the greatest efficiency, lubrication is a factor of increasing importance. What we may term the physics of lubrication is comparatively a new field of research, and so little is known of the laws of the subject that the Institution of Mechanical Engineers some time ago appointed a special committee to investigate and report. This committee did much good work, and although Beauchamp Tower, Dewrance, and some few others have also worked in this field, we are still without a satisfactory theory of lubrication. The latest writer is Mr. Iltyd Redwood who, as a chemist, is more concerned with the composition of various lubricants than with their practical use. Engineers as a class rarely bother themselves about the chemical composition of the materials they employ, and much of the contradictory experience of which one hears so much can be attributed to the absence of exact information regarding the composition of the material employed. Every engineer knows, or rather thinks he knows, how to select a good lubricating oil, but the tests, or what passes for such, have little practical value unless they also include a fairly complete analysis. Mr. Redwood has, therefore, rendered a good service in putting into the hands of engineers a treatise which while mainly chemical is yet written largely from the point of view of the user. He divides lubricants into two classes—oils and greases, the former including mineral, fatty, and "other" oils, while the latter is represented by compounds of oils and fats that are solid or seem solid at the ordinary temperature. This is hardly a scientific classification, but it is a practical one. We should rather prefer to have three classes—animal, vegetable, and mineral.

The description of mineral oils is rather brief. Speaking of the tests for a mineral lubricant he says that the specific gravity and viscosity tests count for little. This is so, unless the viscosity is measured at a high temperature. He shows us how viscosity can be obtained by means of wax as an adulterant. He neither puts much faith in "testing machines," neither do we, unless these express the lubricating value of an oil in terms of work. Thus a shaft will absorb so many foot-pounds with one lubricant, and so many foot-pounds with another. This really is the best test. The chapter on fatty oils is very good for the information it gives of various compositions. What is termed compounding seems to us to be but a euphemism in many instances for adulteration. In the chapter, "Test of Oils," there is again much valuable information, and with the aid of a few reagents the engineer should have but little difficulty in determining whether his oil is adulterated. There is a useful chapter on the action of oils on various metals. In conclusion, this is a work which automobilists will do well to read, as the use of a suitable lubricant is of the utmost importance in fast-running light oil-motors.

"Duncan's Manual of Tramways, Omnibuses, and Electric Railways." 21st Edition. (London: T. J. Whiting and Sons, South Place, E.C., 1898.) Price 3*s*. 6*d*.

As this work is so well-known and, we may add, so much appreciated, any lengthy review would be superfluous. We have only to say that the work is in its 21st edition and is quite up to date. Those of our readers interested in motor-vehicle schemes will find this work exceedingly useful.

Les Sports Modernes. l'Automobile. Paris, 24, Boulevard des Capucines; London, Goupil and Co., 25, Bedford Street, Strand. Price 2 francs.

Automobilism is, at any rate in France, essentially a modern sport. Our artistic and cultivated neighbours have found out that horse-racing, hunting, and the like, are barbarous and degrading pursuits, tending to brutalise rather than refine, and as "sports"—save the mark—now obsolete, or fast becoming so. Automobilism, on the other hand, is free from animal associations, it requires intelligence and skill of a cultivated kind, and hence it is essentially the relaxation of educated persons. For this reason the English mobs used to bowl when they saw a motor-vehicle, and for this reason our bucolic magistrates exhibit not infrequently an intensely splenetic discrimination against automobilists who come before them to receive Justices' justice. For this reason, too, the literature of automobilism is not likely to be appreciated by those who seek what they term "sporting intelligence" in the columns of the halfpenny evening papers. Automobilism is, as we say, in France a sport, and hence it is very fitting that a journal should be established that would deal with automobilism from the sporting point of view. *Les Sports Modernes* has been established for the purpose of dealing, as its title implies, with modern sports, and very properly has devoted its first number to automobilism. This first number is an excellent example of French illustrated journalism, quite eclipsing any of our weeklies. We do not know how it is that the French printers can produce such well-coloured illustrations and English printers seemingly cannot, or, at any rate, do not. In the number before us are several well-executed coloured and plain illustrations of great artistic merit. The articles are mainly historical and descriptive, and are well written. The technical matter is well done—not too technical but sufficient to give amateurs some good practical information. The various types of motor-vehicles are well described and illustrated, as are the more prominent automobilists. We gather that it is *de rigeur* in France for *chauffeurs* to affect a special costume, of which a cap, generally of the Russian naval pattern, is the principal article. When the German Emperor was in England he made the German naval cap fashionable amongst yachtsmen and others who are not, but who like to look like, naval or mail steamship officers. We observe that British automobilists are affecting the use of the German, Russian, or British naval cap. This is not good taste, and we also observe that such well-known automobilists as Comte de Dion, M. Daimler, M. Bouton, Sir David Salomons, Professor Redwood, to mention but a few names, do not, as might be imagined, offend in the manner indicated. A distinctive costume for automobilists, including a cap, may or may not be desirable, but a naval cap on a landsman is, at all times and under all circumstances, an incongruity that we protest against vigorously. In *Les Sports Modernes* is a special article on the "Costume of an Automobilist," and illustrated examples are given. A *chauffeur*, we learn, wears in the summer time a tourist jacket, knickers, and gaiters, the whole surmounted by a Russian naval cap. In the winter a long fur coat is worn; in this costume the *chauffeur* resembles a Russian Customs officer. A chief engineer of an automobile is dressed somewhat like a British bandsman in a quasi-military costume and military cap; his assistant is habited like a commissionaire, but with a plain military cap. It will thus be seen that the philosophy of clothes occupies the attention of our contemporary as well as the philosophy of automobiles.

The Engineering Magazine.—The June issue contains, among other interesting matter, a capital article on "Great Naval Guns," by L. J. Prindle, which is well worth reading. An equally interesting but more amusing article is "Unprofitable Engineering Projects in Western America," by A. G. Allan. From this we learn that the methods of exploiting, so graphically described by Dickens 30 years ago, still flourishes exceedingly, and if anything are improved upon. There is something distinctly humorous in the idea of selling a "dry canal" and "giving away a garden tract," the said tract consisting of granite boulders. A. Horrick describes "The Ground Current of Electric Railways," and shows the methods adopted for preventing electrolysis. As relating to one branch of automobilism, "Dredging on the Mississippi," is a readable account of the difficulties experienced in maintaining open channels in that river.

Cassier's Magazine.—In view of the war between the United States and Spain, Cassier's is especially interesting, the present number being a purely naval one. It comprises the following articles, all well written, well illustrated, and the whole well printed:—"The Ram in Modern War Fleets." In combat and collision. In the British fleet. In the French, Italian, and German fleets. With 49 illustrations. By William Ledyard Cathcart. "Modern Ships of War." A brief review of different types. With eight illustrations. By Lieut.-Commander Richard Wainwright, U.S.N. "The Spanish Armada." Its defeat in 1588. With 17 illustrations. By Charles N. Robinson. "Some Practical Notes on American Battleships. As seen by 'The Man Behind the Gun.'" By E. W. Eherle, U.S.N. "Battleships of the United States Navy." A review of the ships now in service. With 10 illustrations. By George H. Shepard, Engineer Corps, U.S.N. "Mechanism of Modern Naval War." The increasing complexity of modern naval vessels. Illustrated. By Charles H. Cramp. Current Topics—"Modern Warships in Conflict," "Auxiliary Steam Machinery Aboard Ship," "The Stevens Rotating Armourclad," "An Early Dutch Ironclad" (illustrated), "Should Twin Screws of Ships Turn Inwards or Outwards?" "Armourclad Torpedo Boats," "The First British Man-of-War," "Ventilation in Warships." Considerations of space prevent us dealing with these any further than to mention them, but we may say that the article on the "Spanish Armada," by Captain Robinson, R.N., the well-known naval editor of the *Army and Navy Gazette*, is distinctly good reading, and is the best account of this great naval episode we have seen.

Revue de Méchanique is as usual brimful of high-class matter. Perhaps the article which is of especial interest to automobilists is on "Superheated Steam," by M. Sinigaglia. M. Rateau continues his exhaustive analysis of the theory of turbines and luxuriates in mathematics in his task.

We have also received:—*Science Abstracts, The Journal of the Society of Arts, The Indian Engineer, Industries and Iron, The Practical Engineer, Transport, Coach-Builders' and Wheelwrights' Art Journal, The Journal of Acetylene Gas Lighting, Knowledge, Machinery Market Review, Phillips' Monthly Machinery Register,* *The London Chamber of Commerce Journal, Indiarubber World, Cyclist, Scottish Wheel, Irish Field, The Yachting World, The Engineering Magazine, La Revue de Méchanique, La Locomotion Automobile, La France Automobile, L'Industrie Velocipédique et Automobile, L'Automobile Illustré, La Moniteur Automobile, La Revue des Transports Parisiens, Les Sports, L'Energie Électrique, Der Motorwagen, Samokat, Horseless Age, American Wheelman, Transactions of the American Society of Mechanical Engineers, Transactions of the American Institute of Electrical Engineers, Journal of the Western Society of Engineers, The Motocycle, The Scientific Australian, The Austral Wheel, Australasian Coach-Builder and Saddler*, &c., &c.

CATALOGUES.

ERNEST SCOTT AND MOUNTAIN (Limited) have issued a catalogue of their specialities in engines, boilers, dynamos, &c., which, for fulness of information and copious illustration, leaves little to be desired. The work forms, in fact, a kind of trade text book, so excellently are the various machines described. The branches of engineering followed by this firm are many and varied, and range from electric lighting and welding plant to coal cutting machinery and forced draught fans. The information relating to these various appliances is extremely full and plain, so that an ordinary clerk would have no difficulty in placing an order without the aid of any engineering knowledge. Altogether an excellent catalogue and most useful book for the office.

MAKERS and designers of motor-vehicles will do well to obtain the catalogue and price list of Messrs. W. E. Cary, of Manchester. This firm makes a speciality of all parts used in vehicle construction, and have a deservedly high reputation for the excellence of their springs and axles. In the arrangement of their catalogue a system of various-coloured lists for the various articles is adopted, with the result that one can at once find a description and price of any article without having to turn over a multitude of pages. We notice some new designs for motor-vehicle axles.

MESSRS. JULIUS HARVEY AND CO., of 11, Queen Victoria Street, E.C., well known in the motor trade on account, amongst other things, of their success with Post Office work, have sent us an illustrated list of steam motor-vehicles, and are prepared to quote and supply not only these, but also oil or electric motor-cars of every description.

PETROLEUM COMMITTEE'S REPORT.

AFTER an inquiry extending over four Sessions the Select Committee on Petroleum have now concluded their labours. Those members of the Committee who had agreed with the Chairman in opposing the raising of the flash point were at the final meeting on the 13th inst. in a majority, and could have rejected the report by a majority of two. They still felt unable to support it so long as it contained the recommendation which was inserted some weeks ago. In view, however, of the practical value of other recommendations, especially as to storage and transport of petroleum, and in order that the work of the Committee should not prove futile and without result, two of the majority withdrew from the room to avoid voting when the final question was put, and the Chairman did not vote, which enabled the advocates of a high flash point to carry the report by a majority of one.

The following is a summary of the recommendations agreed to :—

1. That the present law affecting petroleum spirit, not being adequate for public safety, should be amended in the manner specified in the report.
2. To adopt a flash point of 100° (Abel close test) as the dividing line between petroleum oil and petroleum spirit.
3. Legislation to control the storage, transport, and sale of petroleum generally and admixtures of the same with other substances, certain heavy oils being exempted.
4. To provide for an efficient system of testing.
5. To provide for adequate supervision and administration by local authorities.
6. That official inquiries be made into the causes of accidents arising from the storage, transport, or use of inflammable liquids.
7. Statutory powers to enable the Secretary of State to issue orders affecting the manufacture and sale of lamps.
8. To spread information among the public as to the nature of petroleum and the management of petroleum lamps.

The Committee added to these recommendations the following conclusions :—

"That to place such legislative restrictions on petroleum oil below 100° (Abel close test) as are placed on petroleum spirit would have the effect of preventing the use of such oil for domestic or trade purposes; that the effect of such legislation would be to materially raise the cost of petroleum to the consumer; that it is in accordance with the evidence that, if immunity from accidents is to be secured, it will be necessary to prevent the use of oil below 100°; that the number of lamp accidents has not increased out of proportion to the vast increase in the number of lamps used; and that if freedom from accidents is to be secured ordinary care must be exercised in the use of petroleum, whether of 73° or 100° flash point."

CORRESPONDENCE.

*** *We do not hold ourselves responsible for opinions expressed by our Correspondents.*

*** *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion or containing queries.*

*** *Correspondents are particularly requested to write on one side of the paper* ONLY, *to place the subject of their letters as a headline at the top of the sheet, and their names and addresses at the foot. Attention to these matters saves much time and ensures the insertion of the letter.*

A COMMENT ON THE LIVERPOOL TRIALS.

To the Editor of THE AUTOMOTOR.

SIR,—The appearance of Messrs. Thornycroft's six-wheeled vehicle at the Liverpool trials is an interesting circumstance, though the articulation limits it to forward movement only. At the same time, its steering capabilities in that direction are obviously superior to those of the "Lifu" lorry, No. 1, with its truly portentous wheel base. Why, in the latter case, the driving-wheels could not be placed "amidships" and trailing steerers provided, it is difficult to see: unless a *furniture wagon* is to be regarded as the model for motor-vehicles, rather than our well-tried friend the *locomotive*.—I am, &c.,

ALFRED J. ALLEN.

London Institution, E.C., *June 27th.*

INSURANCE AND THE STORAGE OF PETROL.

To the Editor of THE AUTOMOTOR.

SIR,—Since writing the letter which appeared in your last number on the "Storage of Petrol," I have at last managed to exact a reply from the two insurance offices I am interested in. They both will allow me to keep 40 gallons of petrol in the two tanks, authorised by the Local Government Board, *in my house*, without detriment to my policy or increase of premium.—I remain, Sir, yours faithfully,

F. M. GOWAN.

26, Clarendon Square, Lesmington.

[Should the attempt that is being made to raise the flash point of common petroleum succeed, the latter will become a "dangerous substance," and hence the insurance companies will probably raise the premium on all policies covering the storage of petroleum of all kinds that flashes under 100° F.—ED.]

TANGYE'S REVERSING GEAR FOR UNI-DIRECTION MOTORS.

IN applying a gas or oil engine to the propulsion of vessels or motor-vehicles, we can hardly do without a separate reversing gear, except in the first instance, when we can propel the boat by means of a reversible screw, as carried out by Messrs. Tolch and Co., the arrangement of which latter we presume to be known to our readers.

In other cases we find special means for reversing devised, among which the "White" gear is noticeable as being comparatively simple, compact, and efficient.

Referring to the accompanying illustration, the engine crank-shaft, A (*see* Fig. 1), engages the shaft, B, which may be the propeller shaft, or say, the countershaft when in a motor-vehicle, by means of four mitres, *a*, *b*, *c*, *d*, of which two, *d*, *d*, run loose on their respective axles, c_2, c_2. The latter are in one with the bush, *c*, which in turn runs loose on the prolongation, A^1, of the engine-shaft, A.

The axles, c_2, revolve with the brake blocks, f_1 and f_2, which latter may be, at the will of the operator, expanded so as to press radially against the ring, *e*, *e*, which is a fixture, or they may be caused to produce friction with their inner ring surfaces on the rims, a^1, a_2, b^1, b_2, of the mitre wheels, *a*, *b*; they may finally be brought in such a position relatively to the fixed ring and the aforesaid rims, so as to clear both when rotating.

These operations of the brake are effected by means of the lever, n^1, of

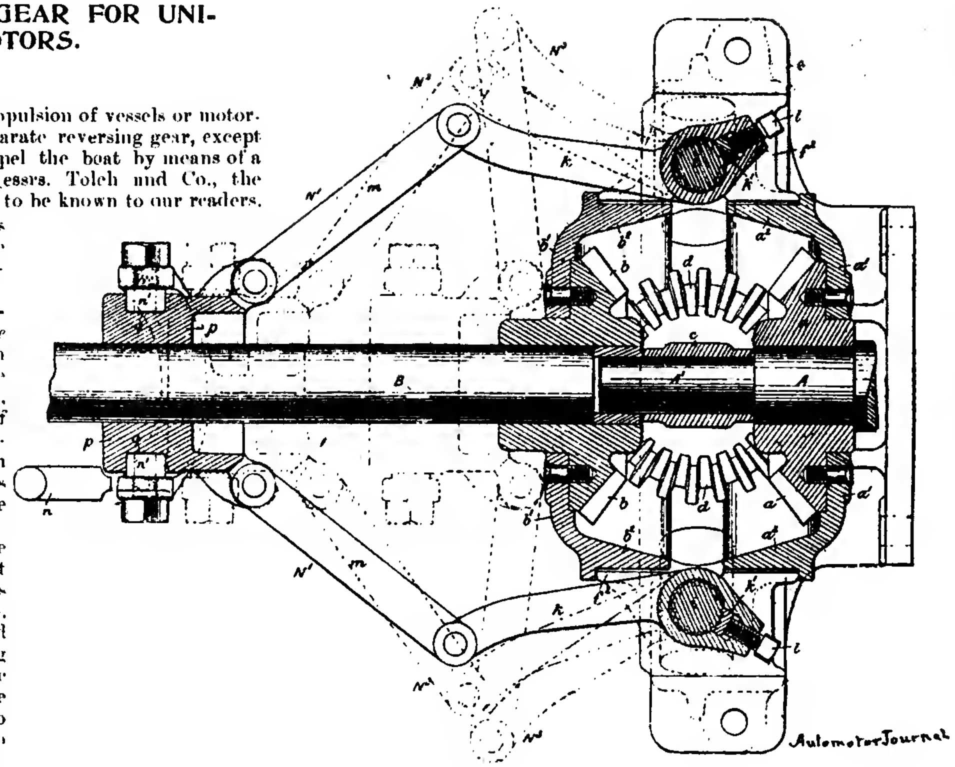

FIG. 1.

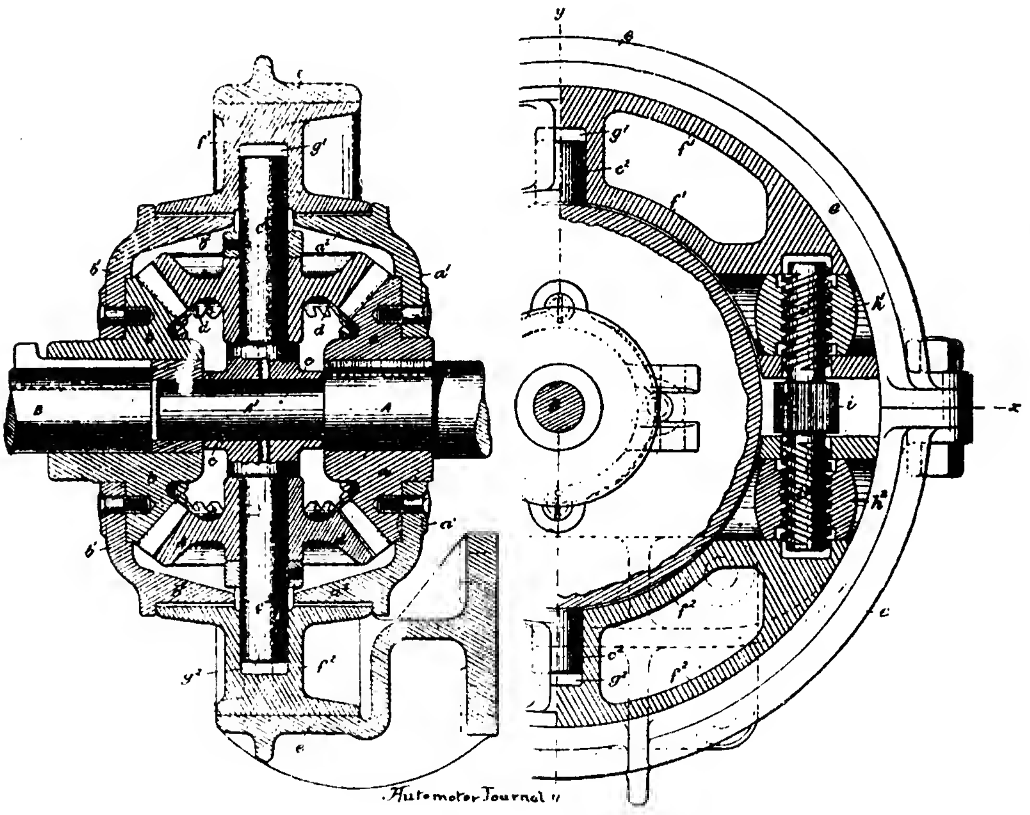

FIG. 2.

the clutch collar, *p*, the latter running loose on shaft, B, which lever, through N^1, *m*, and *k*, can be moved so as to turn the double screw, i^1, i_2 (*see* Fig. 2).

This screw carries right and left hand thread, the part between the threads is serrated, so as to allow of easy adjustment of lever, *k*, by means of a serrated key. When the screw is turned it will either bring the two nuts, h^1 and h^2, nearer to each other or farther apart, it will therefore also expand or contract the brake blocks, f^1, f^2, in which the nuts are let in. When P is in the left hand position (*see* Fig. 1) the brake is applied externally, making cc_2, c_2 stationary, and, as it were, part and parcel of the ring, *e*; in this case B will turn with equal speed, but inversely to A.

In the position at the extreme right (shown in dotted lines), the brake is brought to bear on a_2 and b_2, therefore A will directly rotate B through the medium of a_2, f_2, f_2, b_2, in the intermediate position the brake establishes no connecting bridge, so that the vehicle or the boat is not being propelled whilst the engine runs.

To transmit more or less speed in one sense of rotation or other, the brake blocks are moved more or less inwards or outwards. This device, as already remarked, we consider compact and mechanical, but we must express our doubt as to the above-mentioned capacity to vary speed, such a variation could only be effected whilst considerable slip goes on; this taking place under pressure means waste of power, besides undue wear when of long duration. Furthermore, we know by experience that clutches of this or similar type are, as a rule, either very efficient in "slipping" or in "biting," and the gear in which these two opposite qualities are combined must possess very great merit.

FOREIGN NOTES.

The Concours des Poids Lourds will be held at Versailles in October next, and the vehicles will traverse the same routes as last year.

In order to gratify the wishes of those who like to go as fast as they can on their motor-vehicles, and to do this without risking a prosecution for excessive speed, it is proposed to establish an automobile drome in Paris.

An English branch of the Panhard and Levassor Company has been formed, with a capital of 2,500,000 francs, to sell these vehicles in England. There will be four directors, two French, MM. Pierron and Bouhey, and two English.

A Commission composed of MM. Sartiaux (as President), E. Hospitalier (Vice-President), Beau, Eschwège, Fontaine, Hérard, Mildé, De la Valette (members), and with M. Geoffray as Secretary, has been appointed by the French Automobile Club to study the question of the supply of electric current to automotor vehicles.

At a recent meeting of the committee of the Automobile Club of France a letter was read from a firm of accumulator manufacturers. In this letter the firm, whose name did not transpire, offered to set aside a sum of £1,000, to be given to the maker of any accumulator which could be proved to be better than their own. The committee resolved to write to the firm in question, stating that they were willing to accept the £1,000, and to make it a prize for the best accumulator in the secondary-battery competition, which it is proposed to hold next winter.

The "Fleuri Automobile" is an annual event projected by the *Journal des Sports*. It, as its name implies, is a procession of garlanded motor-vehicles, and its purpose has been to do for motor-vehicles what the May day procession does for horse-vehicles—that is, to create and foster public interest in them. The idea is a good one, and this year the procession was unusually successful, as in Paris just now there are a great many motor-vehicles, attracted thither by the Exposition of Automobiles in the Tuileries Gardens. Nearly every type of motor-vehicle was represented, and all covered in flowers. The procession was a great success, and there was not a single hitch with the machinery of any of the vehicles.

The great and increasing popularity of automobilism in France among the females of what a lately deceased statesman used to term the "leisured classes" is to be explained by the fact that it makes no demand either upon muscular exertion or conventional rules, and, lastly, is select because expensive. Cycling has ceased to be—indeed, it never has been—a very fashionable or favourite exercise with the wealthy and healthy females, because it involves considerable muscular effort, and to indulge in it with safety necessitates the use of a bifurcated garment, which many women with strong hereditary prejudices object to wear. Cycling, too, is cheap, and the possession of a cycle is not evidence of the social or financial standing of the owner, whereas a motor-vehicle and membership of the A.C.F. is at least evidence of superior, if not of excessive, means. That automobilism is fashionable may be gathered from the fact that the halfpenny London papers, which are read by members of the toiling masses, naturally devote columns to automobilism in Paris.

In our last issue we commented upon the fact that the British War Office has not yet learned to appreciate the utility of motor-vehicles. It will no doubt make some experiments in a few years' time, after every other military Power has decided to adopt motor-vehicles. The French military authorities are carefully examining the question of the employment of motor-vehicles, and at the recent manœuvres several of the latter were tried. General Jamont is the first commander who has reported on the innovation, and his experiences in Morvan have been so satisfactory that the Ministry of War is about to acquire a number of motor-vehicles for scouting purposes. Others to carry six men have also been ordered for service with the artillery.

A circular of the French War Ministry inviting owners of automobiles to present themselves for military service with their vehicles is evidently destined (says the Paris correspondent of the *Daily Chronicle*) to alter the condition of the French army. Even in time of peace the experiment will be generalised in manœuvres and by the commissariat department. The saving of time and economy in horses appear incalculable, according to the report of Lieutenant Gerard, whose suggested method for quickly furnishing the military authorities with necessary data is that now applied to all vessels, including pleasure yachts, by the Ministry of Marine. The circular signed by General Billot virtually enjoins registration, by which automobiles of all kinds are made subject to the call of the War Office.

According to the Paris correspondent of the *Morning Post*, the French Courts have relieved Comte De Dion, the well known sportsman and automobilist, from the legal guardian appointed in 1879 to manage his affairs. Comte De Dion has in recent years given proof of a business talent of which he showed little promise 20 years ago. In 1887 he and two partners founded a tricycle and motor-vehicle factory, which now employs 450 workmen and clears a profit of 100,000 francs a month. In the circumstances it is not to be wondered at that the Court made no difficulty in granting Comte De Dion's request to be relieved of his judicial trustee. We congratulate the Count not so much for his resumption of his civil responsibilities, but more for the extraordinary business capacity and prudence he has developed.

The Liverpool Corporation and Automobilism.—As one result, partial or otherwise, of the recent heavy motor-vehicle trials in Liverpool the Corporation has placed an order for a steam refuse van with the Lancashire Steam Motor Company, of Leyland, the builders of what will historically be known as the "No. 5," which, on the whole, made an admirable performance at the trials in question, and which also, as shown by the table published in our last issue, exhibited great economy in fuel consumption. The new van is to carry from 4 to 5 tons, and will no doubt embody the experiences gained during the trials. We should like to conclude with the usual stereotyped congratulations for everybody concerned for doing what any respectable municipal corporation should have done at least two years ago. We however must be just and impartial, and so we cordially congratulate the Liverpool municipal authorities on their sagacity and remarkable enterprise in following the example set by the municipal authorities of a small village on the banks of the Thames called Chiswick.

The Paris Cab Trials.—According to *L'Eclairage Electrique*, the cost per kilometre of electrical vehicles at the time trials in Paris was about 0·05 franc, on the basis of a charge of 0·30 franc per kilowatt-hour, at which price it is sold in the section of the Place Clichy. Each vehicle, in fact, expended current to the extent of 2½ to 3¼ francs' worth on the route of 60 kilometres, the current consumed varying from 9·73 kilowatt-hours up to nearly 14 kilowatt-hours in different vehicles. Petroleum vehicles cost very much more. The minimum consumption of petrol by the Peugeot vehicle was 13 litres per day. Petrol cannot be bought for less than 0·6 franc per litre. Thus the journey cost would be 7·8 francs, or practically 78 pence for 39 miles, being practically 2*d.* per mile—an amount heavy enough for two persons, being equal to a third-class railway fare. The expense in repairs, &c., of the electric accumulators has been given as 3 francs per day per vehicle. Added to the cost of the energy, this implies a cost of about 6 francs, as against 7·8 for petrol—not a wide difference after all, but sufficient to show the success of electric vehicles in city work, and establishing this form of energy as cheaper than others.

THE LONDON STEAM OMNIBUS COMPANY (LIMITED).

That motor-omnibuses will in the near future be the chief form of public conveyance in our streets there is little doubt. But, in our opinion, this greatly to be desired end will hardly be helped forward by the statements set forth in the prospectus of the London Steam Omnibus Company. Why it should be deemed necessary to issue such a badly-drafted document we cannot understand. Plain facts and figures arranged fairly and with discretion should surely have more weight with investors than the reiteration of absurdly-worded comparisons between the existing omnibus and tramway companies and the 400 *proposed* steam and petrol omnibuses of this new Company. We thoroughly believe in the future of motor omnibuses, and we therefore regret the form in which the London Steam Omnibus Company's prospectus is issued. The directors are all experienced and practical men, and the Company will undoubtedly possess the right to build vehicles of a type to suit the requirements of our suburban traffic; but to capitalise the Company upon the estimated immediate earnings of 400 steam and petrol omnibuses, which have still to be built, is an insult to the common-sense of even the simplest investor. The directors have certainly not been pessimistic in accepting as a basis for estimating dividends the calculation of the accountants that the takings of the Company will amount to £353,600 per annum, such revenue being arrived at by multiplying Mr. Sidney Straker's estimated 400 omnibuses (which he says "should in due course be able to be placed upon the road by the Company") by the average takings of the London General Omnibus Company, viz., £17 per week per omnibus. How Mr. Straker arrives at his calculation that the Company will have funds available to place 400 omnibuses upon the road ("probably 200 of steam and 200 of petrol") we fail to see, even allowing that the entire capital be subscribed, considering the onerous terms of purchase, and as he states his figures are based upon the official report of last year's heavy trials of the French Automobile Club. In this report (*see* The Automotor, p. 135, Vol. II, January, 1898) it will be found the prime cost of a De Dion and Bouton steam bus to carry 16 passengers is 22,000 francs. Allowing, therefore, that the suggested 200 be purchased, these alone would swallow up about £176,000. The terms of purchase referred to are as follows:—

As the consideration for the granting of a license to use certain patents under certain conditions the purchasing Company (the London Steam Omnibus Company) shall allot and issue to the licensors, the British Motor Company (Limited), or their nominees, 21,000 fully paid-up shares of £10 each in the capital of the purchasing Company in ordinary and founders' shares, there being allotted and issued one founder's share for every 20 ordinary shares or cash in lieu of such ordinary and founders' shares, or partly by such fully-paid shares and partly in cash, provided that all subscriptions for shares in the capital of the purchasing Company prior to completion as mentioned in Clause 2 (undertaking to grant license within 50 days of purchasing Company going to allotment), shall be applied as to one-half thereof to working capital for the working of the business and the construction and purchase of omnibuses, and as to the other half thereof to the licensors in reduction of the said purchase-money, and any balance (if any) then remaining unsatisfied shall be satisfied by the allotment and issue on the terms as to founders' and ordinary shares as aforesaid of fully-paid shares in the capital of the purchasing Company to the nominal amount of such balance.

As to the question of value of this license, for which £210,000 is to be paid, in the first schedule to the agreement the British Motor Company are careful to protect themselves by not guaranteeing the validity of any of their patents for which they are granting licenses. The licenses to be granted hold good only so far as the licensors are empowered to grant licenses. Which may mean nothing. Further on they even more clearly protect themselves from guarantee as follows:—"The licensees shall not at any time hereafter dispute or question the validity, utility, or novelty of the said inventions, or any of them, or any letters patent granted in respect thereof, and nothing herein contained shall be deemed or construed as a guarantee or warranty on the part of the licensors of the validity, utility, or novelty of the inventions or letters patent, or that the same, or any of them, are in force or of effect or subsisting." Truly a nice waiver clause to have in an agreement undertaking to pay £210,000 for an article which may turn out presently to have been absolutely valueless at the time of sale. In the face of the price asked, and the many statements as to these wonderful patents, the least the subscribers should receive should be an absolute guarantee of the validity of each patent licensed. Apart from the value of the patent rights and the financial soundness, or the reverse, of the proposed scheme, and ignoring the bombastic padding and extraordinary get-up of the whole prospectus, which savours more of a Richardson's show play bill than a business proposition for business people, a few of the figures and facts set forth are well worth study as giving some idea of the possibilities of the future of automobilism for the people. Thus the recital of the carrying and earning power of the leading omnibus and tramway companies fairly takes one's breath away. There can be little doubt that sooner or later a very large proportion, if not all, of these vast numbers will be conveyed by automotor-vehicles, but considering the unavoidable slowness of the makers in turning out motor-vehicles, we hardly think anything beyond a small percentage of the passengers can possibly be taken away by motor-omnibuses for some years to come, and we feel perfectly certain that such astute gentlemen as preside over the affairs of the present omnibus companies are not likely to allow their business to be entirely appropriated when they can so easily adopt steam and other motive power to their own systems, when they consider they are justified in that step. We certainly believe, if the aims of the London Steam Omnibus Company are carried through to a commercial success, that it will be a great lever to force on the existing horse-omnibus corporations to substitute mechanical traction for the present objectionable method. And, therefore, irrespective of patent rights, if the capital of the London Steam Omnibus Company is subscribed sufficiently to enable the commercial possibilities of mechanical passenger traction to be successfully demonstrated, we shall be glad to congratulate the shareholders upon their investment, the management upon its ability, and not begrudge the promoters of the concern the price obtained, although to our mind it is very far in excess of any sum that should under any conditions be asked, considering the many difficulties and weak points to be overcome, the heavy capitalisation thereby created giving little promise of shareholders *ever* realising a return on their investment. The British Motor Company, if their protestations as to the enormous value of their patents be genuine, should not hesitate to take all their interest in *deferred* shares instead of taking pound for pound *in cash* with the Steam Omnibus Company of all the moneys subscribed by shareholders for the practical purpose of bringing those patents into an earning condition.

The vendors are quite generous when they state that, "with a view to showing their confidence in the future of the business, and in order that the cash subscribers may receive out of the profits of the purchasing Company a dividend on their shares before the vendors' shares rank for dividend, the licensors hereby agree that the fully-paid ordinary shares (if any) allotted to them hereunder shall be deferred as to dividend in the manner and to the extent following, that is to say: No dividend will be payable on the vendors' shares until the business has earned a net profit of more than 6 per cent. upon the capital subscribed and paid up. The vendors' shares are then entitled to dividends until they have received 6 per cent., when all the shares are entitled to rank equally for dividend. After the Company has paid a dividend of 6 per cent. upon its entire issued capital, the distinction between the two classes of shares will thereafter cease."

This is all very well after a sum of over £100,000 in cash (which, at the discretion of the directors, might even be increased to £210,000 in cash) has been provided for. What is wanted is that the "confidence" should be carried a step further, and this £100,000 odd be allowed to remain in the coffers of the Company. If the *whole* of the subscriptions were to be available for working capital, and the vendors or licensors were willing to take the *whole* of their interest in deferred shares, even allowing such shares to take a much larger proportion of profits after the preferred shareholders (otherwise those who find the cash to enable the chestnuts to be taken out of the fire) had been paid a fair percentage, then we should deem it right to recommend our readers to subscribe to what might presently be a very valuable security. As the arrangements and capitalisation now stand, however, we consider the scheme to be of a highly speculative nature, and one hardly to be recommended to widows and clergymen.

The engineers appointed by the Municipality of Paris to conduct the examinations for proficiency in automobilism are MM. Walkenaer and Boschet.

"THE AUTOMOTOR" TESTING LABORATORY.

As we are so frequently consulted by our readers and subscribers, both lay and professional, with regard to new inventions, apparati, materials, &c., used in automobilism, we have decided to undertake the testing of such, and for that purpose are making suitable arrangements. These tests will be carried out by competent persons under the superintendence of our technical editor. The conditions on which we undertake to carry out such tests and our charges for making the same, may be learned by application to the office of THE AUTOMOTOR, 62, St. Martin's Lane, Charing Cross, London, W.C. Communications should be endorsed "Testing Department."

Test of Lubricating Oil.

Messrs. Wells and Co., Oil Works, Manchester, have forwarded us a sample of lubricating oil intended for the cylinders, &c., of motor-vehicles, which we have examined with the following results:—

The colour is orange yellow; the oil is very translucent, and when seen by reflected light has a deep bloom or fluorescence. At the temperature of 16° C. its specific gravity is 25 on the Baumé scale, or ·905 as compared with water. Its viscosity, even at high temperature, is very good. The oil flashes at 215° C., or 420·8° F. At this temperature the colour gradually deepens, but the fluorescence is still maintained, and no nitrous fumes are given off. Within the range of temperatures stated no acid reaction was perceived. The oil is a blended mineral oil, and eminently *well suited for the cylinders of motor-vehicles.*

The Lombard Corrugated Rim.

We have received a sample rim from the Lombard Tube Company, Birmingham. This rim has a series of corrugations formed on its inner periphery, which unquestionably greatly increase the ability to resist distortive stresses, and hence a rim of equal strength with existing types can be produced with a decrease of weight. As we have not subjected this rim to any mechanical test, we are unable to state definitely what the exact economical advantage is.

Bickford's Petroleum Burners.

We have had one of these burners (No. 1 B) for some time under varying tests in a water-tube boiler. The burner is of simple construction, and when fitted up and used according to the maker's instructions it is satisfactory in every way. The feature which especially commends itself to us is the provision of a thermal storage in the shape of iron bars fitted over the burner; when these become red hot, as they do in the course of a few minutes, they materially assist in ensuring perfect combustion, and the result is that when the burner is at work there is a nearly pure, non-luminous blue flame without smoke or deposit; this means, of course, that the combustion is complete. To ensure this result in its most perfect form very careful manipulation of the air-supply and the air-pressure is, however, necessary. We obtained the best result when the air for combustion (properly regulated on entering the furnace) was heated by contact with the hot surfaces, &c., and with the petroleum under a pressure of about 8 to 10 lbs. per square inch. Under these conditions there was no visible discharge from the chimney, the products of combustion being pure carbon monoxide. In the boiler in question steam showed at 20 minutes after the burner was in full operation; in another 25 minutes there was 50 lbs. of steam. In a careful test for consumption, in the first hour, allowing for lighting up and imperfect combustion, 9·35 pints of oil were consumed; in the second hour, with everything fully heated, the consumpt was 9·1 pints. The oil was ordinary burning oil, specific gravity ·820, and flashing at 76° F.

While this burner is unquestionably very efficient, it has certain structural defects which, however, may easily be remedied. We think the vaporiser and the two side tubes should be encased, so as to prevent the fall in temperature of the former which occurs when the fire door is opened, or when too much cold air is admitted. The burner also suffers from the defect common to all this type of burner, and which so far has not yet been remedied in any of them, in that it is somewhat noisy, but not excessively so.

For motor-vehicle and steam-launch work we can recommend the Bickford burner, as it is, if properly managed, very efficient. It is easily manipulated, and cheap to make and repair.

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL" by HERBERT HADDAN and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

Specifications Published.

THE following is a List of Specifications recently published, and obtainable at the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform charge of 8*d.* per copy. Owing to the enormous pressure upon our columns it has been found impossible to deal in any other form with the accumulation of patents now being taken out in connection with automobilism. As far as possible, a selection for special mention is made by the Editor from the more prominent inventions:—

Applied for during 1897.

12,924. W. P. THOMPSON (B. Loutzky, Nuremburg, Germany). Four-stroke cycle motor.

13,511. J. R. ARKLE, Meldon Park Farm, Morpeth, Northumberland. Hubs.

17,085. J. RIDGE, Selborne, Hassocks, Sussex. Apparatus for indicating or recording distance, time, and fare.

28,205. H. P. MAXIM, 1, Columbia Street, Hartford, Conn., U.S.A. Running gear and frames.

45. G. H. MIDDLETON and G. MACBETH, 53, Oliver Street, Birmingham. Hubs.

2,378. W. ROWBOTHAM, 27, Vittoria Street, Birmingham. Primary batteries.

8,547. J. E. THORNTON and J. P. LEA, Rokeby, Oldfield Road, Altrincham. Heated compressed-air motors.

8,663. A. HOLMES, Portland Road, Newcastle-on-Tyne. Dynamo-electric machines, or electric motors.

10,042. T. W. NAYLER, Friar Street, Hereford. Mechanism for axles.

10,801. J. SPIEL, 85, Thurmstrasse, Berlin. Incandescent wick burner for liquid fuel.

10,968. W. A. STEVENS and R. A. BARKER, Victoria Works, Maidstone. Governors.

13,032. R. O. Allsop, 37, Norfolk Street, Strand, London. Starting apparatus.
13,309. M. H. Smith, 47, Victoria Street, Westminster, London. Steering apparatus.
13,559. J. Robertson, 412-424, St. Vincent Street, Glasgow. Tyres.
9,276. W. Rowbotham, 24, Harleyford Road, Vauxhall, London. Primary batteries.
9,463. T. Klaus, 103, Route de Versailles, Billancourt, France. Motor-vehicles.
11,861. O. Lindner, 41, Rue Gallait, Brussels. Accumulators.
12,957. A. Muller and H. Tudor, 90, Bergstrasse, Hagen, Germany. Transforming alternating into continuous electric currents, or *vice versâ*.
12,985. G. H. Middleton and G. Macbeth, 53, Oliver Street, Birmingham. Hubs.
13,113. J. Spiel, 85, Thurmstrasse, Berlin. Burners for liquid fuels.
13,402. R. R. Symon and H. A. House, 20, Abchurch Lane, London. Tubulous steam boilers.
13,988. G. G. Hunt, Britannia Works, Wharf Road, London, N. Vaporisers and igniters.
9,107. E. Rossel, 12, Rue des Sarrazins, Lille (Nord), France. Autonotor road vehicles.
9,460. L. Renault, 14, Place de Laborde, Paris. Fluid pressure generators.
9,963. A. H. L. Grivel, 6, Rue des Poissonniers, Neuilly (Seine). France. Carburetted air or internal combustion engines.
10,080. R. R. Symon and H. A. House, jun., 20, Abchurch Lane. E.C. Driving gear.
10,081. R. R. Symon and H. A. House, jun., 20, Abchurch Lane, E.C. Steam or other heat engines.
10,097. C. E. Henroid, 23, Franch Street, Bienne, Switzerland. Internal combustion engines.
11,547. W. H. Casley and A. F. Woodman, 97, Paris Street, Exeter. Hydrocarbon motors.
11,619. P. S. Pilcher, Artillery Mansions, Victoria Street, London. Engines actuated by mixed products of combustion and steam.
14,255. A. A. Common, 63, Eaton Rise, Ealing, W. Power-driven road vehicles.
14,455. H. C. Capel, 168, Dalston Lane, London, N.E. Gas engines.
14,559. J. Simpson, Brachead, Whins of Milton, Stirling. Instantaneous steam generators.
10,519. C. M. Johnson, Broad Street House, London, E.C. Reduction of smell and visible vapour from the exhaust of oil and other explosion motors.
11,334. J. Vaughan-Sherrin, 28, Victoria Street, London, S.W. Electric ignition devices.
11,801. J. Fielding, Upton St. Leonards, Gloucestershire. Vaporising and igniting device.
28,161. V. H. Ernst, 705, Summit Avenue, Jersey City, U.S.A. Steam motors.
10,421. C. Powell, 75, Wiltshire Road, Brixton, London, S.W. Driving gear.
12,117. A. J. Pool, Elmsgreen, Chipstable, Somerset. Explosion engines.
12,225. W. B. Thompson, Thornbank, Dundee. Motor-cars and the traction of vehicles.
13,019. F. J. Gibbs and W. Wright, 70, Lower Hurst Street, Birmingham. Lugs or joining sockets of tubular frames.
13,196. J. Gardner, Marine View, Knott End, Fleetwood, Lancs. Chain gearing.
10,804. W. Baines and others, 5 and 6, Great Winchester Street, London. Motor or power-driven cycles or other vehicles.
10,961. J. F. Sargeant and F. Longhurst, Holly Bank, Bracknell, Berks. Handle bars.
11,375. R. E. B. Crampton, Mansion House Buildings, London. Means for attaching crank axles and pedal spindles.
11,951. M. A. Lamy and C. Richard, 36, Rue la Bouyere, Paris. Internal combustion engine.
11,221. Nave. Electric road-vehicles.
13,003. F. Henriod-Schweizer, Marin, Neuchatel, Switzerland. Self-propelled vehicles.
13,020. F. J. Gibbs and W. Wright, 70, Lower Hurst Street, Birmingham. Parts of motor-carriages.
15,147. A. Heinemann and W. Schafer, 78, Koniggratzer-strasse, Berlin. Accumulators.
15,870. A. Muller and H. Tudor, 31a, Luisenstrasse, Berlin. Electrical propulsion.
16,411. N. Seunier, 96, Rue de Longchamp, Paris. Hydrocarbon motor.
17,127. E. Petreano, 95, Boulevard Beaumarchais, Paris. Gas and hydrocarbon engines.
20,145. A. Lehmann and A. Mann, 46a, Georgenstrasse, Berlin. Accumulator plates.
14,126. F. J. Wich, 15, Clyde Road, Didsbury, Lancs. Speed recorder.
14,288. G. E. Davis, District Bank, Ludlow, Salop. Lamps.
14,766. A. Whittall, 4, Comberton Terrace, Kidderminster. Metallic rims for wheels.

1898.

2,757. G. Bapst and A. Greler, 5, Rue Scribé, Paris. Petroleum or gas engines.
686. H. A. Bertheau, Bibliotheksgatan, No. 1, Stockholm, Sweden. Gas and petroleum engines.
1,671. J. H. Kirk and J. W. Jeffs, Jessamine Villa, Orchard Road, Erdington. Frames.
2,332. J. S. V. Bickford, Camborne, Cornwall. Oil vapour burners.
2,013. E. Capitaine, Frankfurt-on-the-Main, Germany. Lamp for heating the vaporiser and ignition tube of oil engines.
2,195. F. Tentschert, V. Franzengasse 18, Vienna. Motor-engine mechanism.
4,743. Leigh (B. J. X. Gosselin, 12, Rue de St. Quentin, Paris). Gas and petroleum motors.
3,993. A. J. Boult (Société Nouvelle des Établissements Decauville Aine. 13, Boulevard Malesherbes, Paris). Electric ignition devices.
3,483. F. F. Swain, 280, Saint Water Street, Chicago, Illinois, U.S.A. Metallic packing.
4,261. C. A. R. Mansfeldt, 36, Pollard Street, South Shields. Metallic packing.
3,992. A. J. Boult, La Société Nouvelle des Etablissements Decauville Ainé, 13, Boulevard Malesherbes, Paris. Carburetters.
3,991. A. J. Boult, La Société Nouvelle des Etablissements Decauville Ainé, 13, Boulevard Malesherbes, Paris. Motor road-vehicles.

6,947. G. E. Whitney, 88, Falcon Street, East Boston, Mass., U.S.A. Motive-power engines.
155. F. Alsina, 16, Rue Codols, Barcelona, Spain. Apparatus for regulating explosion-engines.
6,721. R. Demeuse, Brussels, Belgium. Motor-cars.
2,156. Holt. Lubricators.
5,712. W. S. Sargeant, Strand-on-the-Green, Chiswick, London. Oil-vapour burners.
6,764. H. H. Lake (A. de Forselles, 1, Boulevardsgatan, Helsingfors, Finland). Vaporising burners.
6,961. J. J. Tonkin and J. Eaton, 25, Cortlandt Street, New York, U.S.A. Steam boilers.
8713. B. McInnerney, 619, S. 16th Street, Omaha, U.S.A. Generators for electrical igniters in gas or like engines.

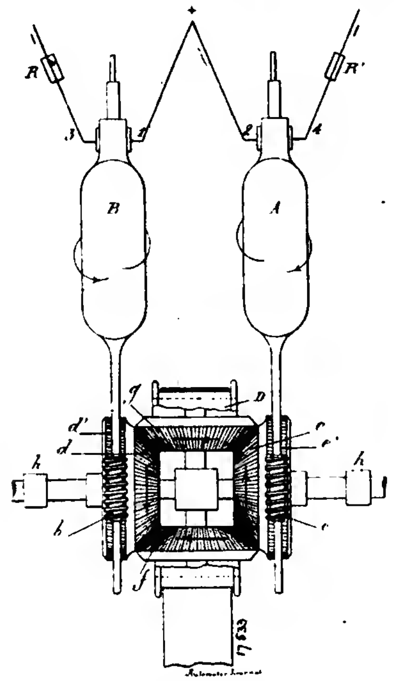
17,533. Differential Gear. G. R. Blot, 16, Rue Drouot, Paris. July 26th, 1897.

Relates to differential gear so arranged as to give facilities for starting, stopping, reversing, or varying the speed of a machine, especially such as are employed to drive motor-cars or vessels.

For this purpose a pair of engines or electric motors, each of which can have its direction of movement, power, and speed independently varied, are connected by suitable gear each to a bevel wheel, these two wheels facing each other and free on one shaft, on which is also mounted between them, free to turn, a drum, sprocket wheel, or toothed wheel, from which motion is conveyed by belt, chain, or gearing to the machine, motor-car, or vessel. Within this drum or wheel, on radial axes, are mounted two bevel pinions both in gear, with both the bevel wheels.

When both bevel wheels revolve with equal speed in opposite directions driving the pinions, the drum or wheel in which they are mounted remains at rest, but when the relative speed or direction of the bevel wheels is varied, then the drum or wheel containing the pinions is driven in the one direction or the other with a speed depending on the relative speeds of the two bevel wheels.

B and A indicate two armatures of electro-motors driven in opposite direction, their commutators having the brushes, 1, 2, connected to the + terminal, and 3, 4, connected to the − terminal of a source of electricity, the velocities of the armatures being varied as required by rheostats, R, R[1]. On the axes of the armatures are



worms, b and c, gearing with worm wheels, d^1, e^1, attached to bevel wheels, d, e, which gear with pinions, f and g, mounted on axes within a drum, D, which drives a belt or might be toothed to drive a chain, or it might be connected by gearing to the machine to be driven. A modified form is also described and shown.

6,947. Motive Power Engines. G. E. Whitney, 88, Falcon Street, East Boston. March 22nd, 1898.

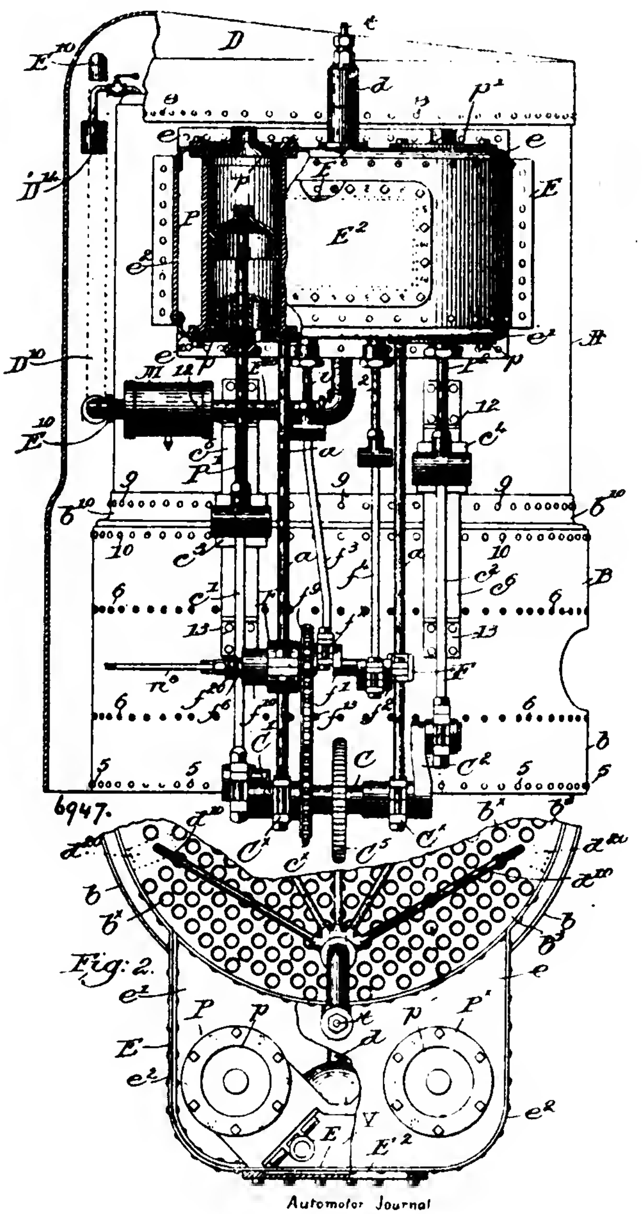
Relates to motive power engine particularly adapted as a motor for a road vehicle, and consists mainly of an upright steam boiler comprising a fire chamber, water leg, and shell, the water leg having inner and outer walls joined at their lower ends and forming the sides of the fire chamber, the outer wall being a continuation of said shell, a lower tube head attached to the inner wall of the water leg and forming the top of the fire chamber, an upper tube head attached to the upper portion of said shell, fire tubes constituting a rigid connection between said heads within the boiler shell, and communicating with the fire chamber, the tubes being composed of a material having a different rate of expansion from that of the material of the shell, and an expansion member interposed between the parts of the boiler which support the tube heads, whereby the difference of expansion between the parts joining the peripheries of the said heads and the tubes joining the interior portions of the heads is permitted without injury. A jacket surrounds the engine cylinder and is secured to the boiler shell, said jacket communicating with the interior of the boiler, an independent steam supply connection between the cylinder and the boiler being provided, whereby the hot water and steam may circulate around the cylinder and valve chest. The cylinder heads are externally removable and adapted to be secured to the cylinder ends.

The engine is mounted externally on the boiler, and comprises its cylinder and main shaft, the beforesaid jacket surrounding and supporting the cylinder and secured to the boiler, bearings for the main shaft, a support for said bearings laterally rigid and adapted to yield vertically, and secured to the boiler shell, and upright brace rods rigidly connecting said bearings and cylinder.

A plurality of tubular branches in the upper part of the boiler lead to a single inlet to the throttle from different points of the upper tube head, and communicate with the steam space, whereby passage of water to the throttle is prevented.

Baffle plates are provided below the tube head and the inner ends of the branches.

A lever connected with the throttle has a fixed fulcrum and a toggle is used, one arm of which is jointed to said lever, the other arm having a fixed fulcrum, and means connected with the joint of the toggle, to straighten or break the latter and thereby rock the throttle actuating lever.



A flue is provided for the escape of the products of combustion, a steam exhaust pipe leading from the cylinder and opening into said flue, and a muffler and pressure equaliser in said pipe between the cylinder and the flue, whereby the exhaust of the steam into the flue is made continuous instead of intermittent, and the steam, or particles of water condensed therefrom is dried and made invisible.

A removable cover is provided for an opening in the jacket adjacent the valve chest, whereby access may be had to either the valve chest or cylinder while the steam in the boiler and in the jacket surrounding the cylinder and valve chest is under pressure.

9,107. Automotor Road Vehicles. E. Rossel, 12, Rue des Sarrazins, Lille (Nord), France. Date claimed, September 11th, 1896. Date of application, April 9th, 1897.

This invention relates to a system of automotor car driven by a petroleum or other engine. The framing of the vehicle is constructed of a double frame of very light steel tubing to which are fixed the engine, A, and the whole of the propelling mechanism contained in boxes, B and C. The carriage body, which is independent of the framing and can be easily dismounted, is secured to the frame by means of six bolts.

The engine, A, preferably of the Daimler oil-engine type, drives, through a friction clutch, E, a central wheel which is in constant gear with four satellite wheels carried by two discs concentric to the central wheel, and capable of revolving about their centre or of being momentarily rendered stationary by the driver by means of a handle, D, placed near the steering handle. Four other wheels are respectively in one with the four wheels previously mentioned, the whole being arranged in such manner that the pitch circles of these latter wheels shall touch the inside of a circle, which is also concentric with the central wheel. Another wheel is keyed upon an intermediate shaft parallel to that of the engine whose pitch circle touches externally the circle, and upon the same shaft is keyed a bevel pinion in gear with a similar wheel keyed on the shaft of the balance gear, T, upon whose opposite ends are keyed sprocket pinions, U, which drive, through endless chains, sprocket wheels, V, fast on the rear driving wheels.

X is a hand lever for acting on brake straps passing round drums, Y, for braking the driving wheels, and Z is a pedal which operates another brake strap acting on a drum, *a*. on the balance gear shaft. On applying one or other of these brakes the clutch, E, is at the same time acted on for throwing the engine out of gear with the driving mechanism. The engine may be slowed momentarily by means of a third hand lever, *b*, acting on the regulator for obtaining speeds intermediate of those afforded by the four combinations of the train of gearing before described. The hand levers, *b*, D, X, are grouped around the steering handle, *d*, as shown, so as to be within reach of the driver, who is thus enabled to instantly and easily execute any manœuvre necessary for the proper working of the vehicle.

The steering handle, *d*, acts on the steering wheels, which swivel on independent pivots through connecting rods and an elbow lever. The fore part of the vehicle is supported upon a single cross spring, *i*, fixed to the lower member of the framing by a horizontal axis, *j*, parallel to the longitudinal axis of the vehicle. The two ends of the spring are connected to the axle by straps, *k*. The axle is connected in the horizontal plane to the framing of the vehicle by two connecting rods, *l*, having ball and socket joints, so that the axle is free to oscillate on axis, *j*, the motion being limited by the spring, *i*, through the straps, *k*, and the axle being guided in a vertical direction by the two universal jointed connecting rods, *l*.

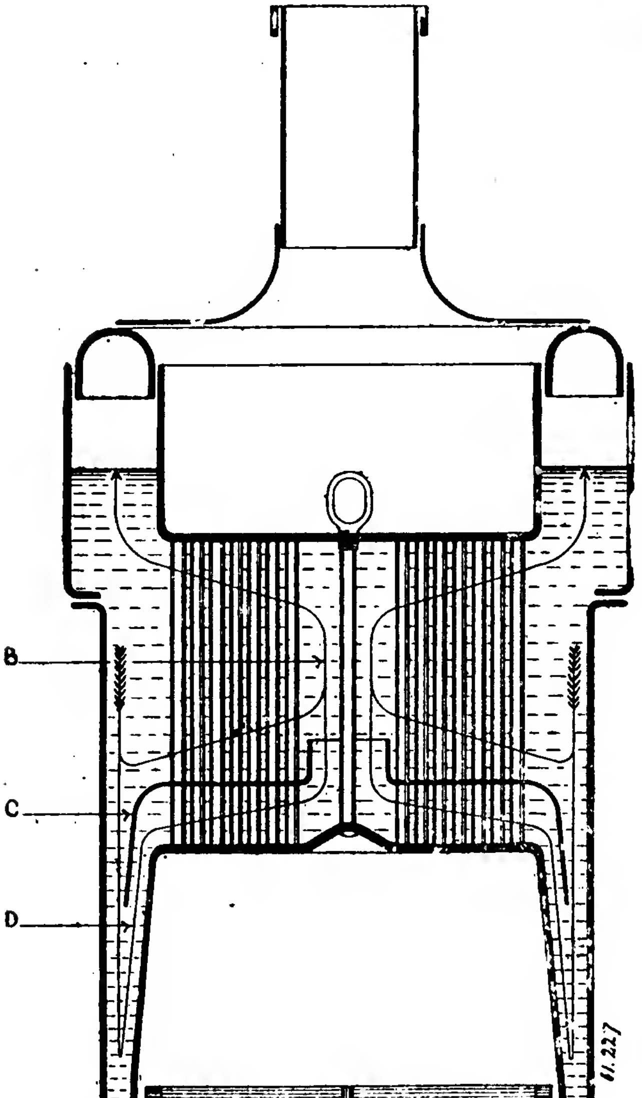
A petroleum tank, e, is placed at the front of the vehicle which is is in direct communication with a constant level carburetter from which the engine is supplied; *f* is a tank containing water for cooling the engine cylinders, for which purpose a small centrifugal or other pump, *g*, driven from clutch, E, by a friction pulley, *h*, is employed for producing a circulation of water around the cylinders and expelling the heated water into the double tubular framing of the vehicle, which serves as a cooler and whence the water is returned to the tank, *f*, and to the engine. A winch handle, *m*, serves for starting the engine through the sprocket wheels, *n*, *o*, and endless chain, *p*.

11,227. Steam Boilers. L. J. Todd, 25, Brooke Road, Stoke Newington, Middlesex. May 5th, 1897.

This invention relates to that class of steam boilers in which there is a firebox in the lower part, from the roof of which fire tubes are carried upwards to a smoke-box, which may be either wet or dry, at the top of the boiler.

The fire tubes are arranged in the furnace roof in an annular manner, so as to leave a large space in the centre of the boiler free from tubes. Then, in the water space of the boiler, a little distance above the top of the furnace, is placed a circulating plate, pierced with holes for the tubes to pass through, and which turns upwards with a large opening into the central space which is free from tubes. When a dry smokebox is used, a deflector is placed in the upper part of the open central water space.

The circulating plate may either be flat, or may be coned upwards from the circumference to the central or other discharge hole; and if desired, may be made to partly surround the sides of the furnace, in addition to covering the top of the same.

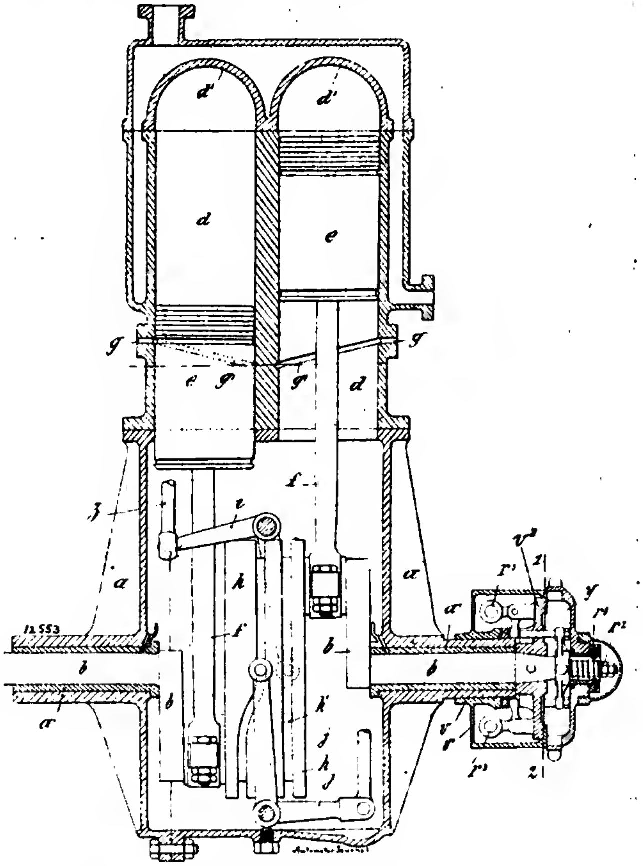


With this boiler a circulation of water, directly over the roof of the furnace crown towards the central or other open space, commences whenever the fire is lighted. And as the heat increases the circulation becomes more rapid, until, with a hot fire, a violent stream of water washes over the furnace top, and pours up the central or other space, until, when meeting with its deflector, it is thereby compelled to spread laterally amongst and throughout the tubes. The lower part of the tubes are thus first washed transversely with a rapid current advancing towards the central or other open space, and are then again washed transversely by the same current returning from the central or other open space towards the outer part of the boiler.

12,553. Petroleum and Like Motors. E. Rossel, 82, Rue des Sarrazins, Lille (Nord), France. May 20th, 1897.

The motor comprises in principle a frame, *a*, formed by two halves of a box united by a tight joint, and together forming an hermetic box or case, in which are provided two bronze sockets or bearings, a^1, through which passes the driving-shaft, *b*. This box is partially filled with oil, which whilst the motor is acting is projected upon the internal walls by centrifugal action, thus ensuring the lubrication of the driving-shaft, the pins, the connecting-rods, and of the different distributing parts, and likewise the partial lubrication of the cylinders and pistons, such lubrication being further provided for by means of a special arrangement which is hereinafter described.

Upon the frame, *a*, are fixed the cylinders, *d*, closed at their upper portions by spherical ends, d^1, which are in one piece with the admission and discharge valve chambers. These valve chambers, the



spherical ends and the upper portion of the cylinders, in which the explosion of the explosive mixture takes place, are entirely surrounded by a water-jacket, in which the circulation is maintained in any convenient manner, and in suitable conditions for keeping the cavities around which it passes at the most appropriate temperature for ensuring the efficient working of the motor.

In the cylinders, *d*, slide the pistons, *e*, provided with segmental parts, and which transmit their motion to the driving-shaft, *b*, by means of the two connecting-rods, *f*.

The lubrication of the cylinders and pistons is completed by means of one or more lubricators communicating with the tubes, *g*, and distributing their oil all round the piston through an inclined transverse groove, g^1, formed upon the inner face of the cylinders; this oil completely lubricates the cylinder, as it is carried along by the two further grooves or channels formed upon the two extremities of the pistons.

The motor is of the four-cycle type, and has two cylinders with cranks placed at 180°. The admission valves of this motor are automatically actuated, and the escape valves are governed by the assemblage consisting of the rods, *z*, the levers, *i*, *j*, and the pulley, *k*, which latter is fixed upon the crank-shaft.

The suction of the explosive mixture is effected by the piston itself; in descending it produces a vacuum above it—the valve rises under the influence of the atmospheric pressure, and allows the mixture arriving by a pipe to pass. During its return, the piston compresses the explosive mixture and closes the admission valve, which is held upon its seat by a spring of suitable tension.

Immediately after this compression the explosion is effected by means of a platinum tube raised to incandescence by a burner of any appropriate description. This tube is fixed by a union upon a second tube of steel, which is screwed in the wall of the valve chamber and opens near to the admission valves in proximity to the inlet for the mixture of fresh gas.

During the second return stroke, the gases are expelled through a valve, and are conducted through a tube into discharge receivers suitably arranged in order to prevent noise and to completely reduce the pressure of the gases before discharging them into the open air. These discharge valves are raised by the two vertical rods, *z*, which are actuated by the two bent levers, *i* and *j*, whose oscillatory motion is produced by the groove, h^1, formed upon the circumference of the pulley, *h*, and by means of the two parts sliding in the said groove. As this groove passes twice round the pulley before returning to its point of departure, the vertical rods only act upon the valves upon every second revolution.

A centrifugal governor placed upon the driving-shaft, *b*, actuates a lever which acts upon the horizontal rod placed in front of the cylinders, and causes by its displacement from left to right the rise of the extremity of pawls, which thereupon engage in the notches formed in the corresponding parts, and force these parts to turn around their respective axes upon the rising of the vertical rods, and thus prevent these rods from causing the discharge valves to open.

The centrifugal governor is regulated for a predetermined normal speed by means of the spring, r^1, and nuts, r^2. When this normal speed is exceeded the balls, r^3, separate from the axis and push from right to left the sleeve, *v*, which slides upon the socket, a^1, of the frame acting upon the lever, *s*, which prevents the discharge valves from rising.

Upon the back of the plate, v^2, carrying the governor, and which is keyed upon the driving-shaft, is arranged a pawl movable around its axis; this pawl tends, under the influence of a spring, to gear with a ratchet-wheel, *y*, having four internal teeth. This wheel, which is loose upon the driving-shaft, is capable of receiving, either by means of a handle or by means of a chain and pinion, a rotary motion in the same direction as the motor; this motion is transmitted to the shaft by the pawl, and, when an explosion takes place, the motor starts and the pawl, which turns with the driving-shaft, disengages itself under the influence of centrifugal force, whilst the wheel, *y*, remains at rest.

One device for the regulation of the admission valves comprises a pinion fixed upon the driving-shaft and driving a wheel on a shaft parallel to the driving-shaft upon which second shaft moves a sleeve having two cams upon which the vertical rods constantly bear by means of the rollers, and an articulated lever which lifts the rods of the admission valves.

The cam sleeve is displaced by the action of the governor. When working at a normal speed, the cams raise every second revolution each of the admission valves. If this speed is exceeded, the governor displaces the cam sleeve, the rollers bear against the cylindrical portion, the rods are no longer raised, no explosive mixture is introduced into the cylinders, and the motor resumes its normal speed.

7,479. Variable Speed Apparatus. J. W. Hall, 1, Wiltshire Road, Brixton, Surrey. April 8th, 1896.

The apparatus consists of a disc fitted on the end of a short shaft which rotates in suitable bearings, and round the face of the disc are fitted several force pumps or cylinders, the connecting rods of the pistons or plungers of which are operated or driven by the engine shaft either direct by a crank, or by gearing. The pumps draw the working fluid from a casing which surrounds the disc and delivers it into a central hole in the short shaft, and motion is given to the vehicle by suitable gearing from this shaft. When the outer end of the hole in the shaft is open, the pumps will deliver their fluid without resistance, and therefore the disc and shaft will remain at rest, but when it is closed by a valve, the pumps will be unable to deliver their contents, and therefore the disc and shaft will be compelled to rotate, and so give motion to the vehicle, the rate of speed depending on whether the shaft hole or pump delivery is wholly or partly closed.

On the end of the short shaft opposite to that which carries the disc is fixed radially to the shaft preferably three or more cylinders which rotate with the shaft, the connecting rods of their pistons being connected to a crank which is fixed, the cylinders revolving instead of the crank.

These cylinders are of greater collective capacity than the total capacity of the pump cylinders, according to the number of times it is desired to gear the revolutions of the disc and shaft below the speed of the engine shaft.

The valves for the distribution of the working fluid to the large cylinders can be worked by an eccentric on the fixed crank-shaft above mentioned, and the passages for the flow of working fluid from the small to the large cylinders can be made through the body of the short shaft.

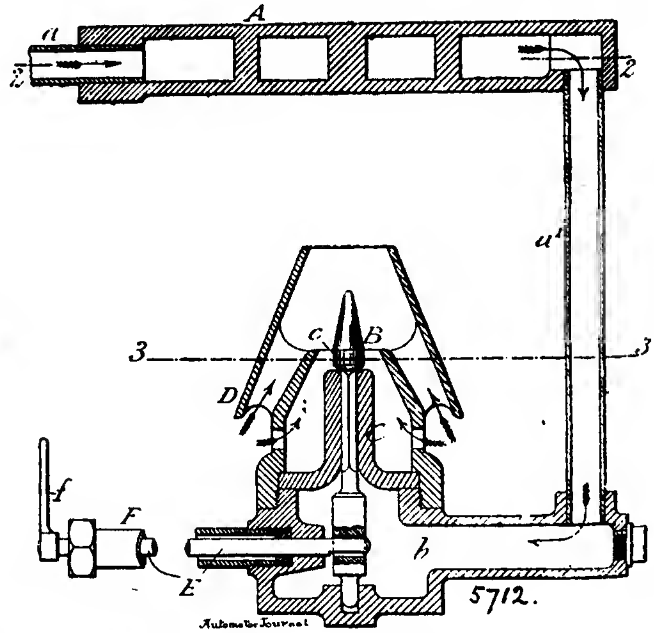
For the purpose of completely stopping or partly slowing down the motion of the vehicle an arrangement may be used to allow the working fluid to pass away from the pump cylinders without doing work on the vehicle, or the valves of the large cylinders may be so fitted as to allow the fluid to pass them without doing work, and when the hill climbing gear is not in use.

This invention may be used for gearing up instead of or in addition to gearing down.

5,712. Oil Vapour Burners. W. S. Sargeant, Strand-on-the-Green, Chiswick, London. March 8th, 1898.

Relates to a burner for the combustion of oil vapour generated by the heat of the burner itself.

A is the vaporiser supplied with a regulated quantity of oil, which enters by the pipe, *a*, and becomes vaporised as it takes a zigzag



course, the vapour descending from an outlet at the opposite end by a pipe, a^1, to a space, *b*, below the burner, B. This burner comprises a central tube, C, through which passes the squared or longitudinally grooved stem of a valve, *c*, and the tube, C, is surrounded by a shield, D, having inlet for air entering as indicated by the arrows. In the lower part of the valve stem there is a slotted hole, in which is engaged the eccentric end of a spindle, E, which extends along a tube, F, and through a stuffing box, and terminates in a handle, *f*, by which it can be turned.

The vapour ascending from the space, *b*, up the tube, C, issues between the valve, *c*, and its seating, and, being ignited while it mixes with the air, forms a flame which heats the vaporiser, A, and, passing upwards around it, serves to heat a boiler or other body situated above the vaporiser.

By turning the handle, *f*, the valve, *c*, can be raised or lowered a little, so as to increase or diminish the flame as may be required.

CONTENTS.

THE PARIS-AMSTERDAM-PARIS MOTO-VEHICLE COMPETITION.

ORGANISED by the Joint Committees of the French and Belgian Automobile Clubs, this procession of motor-vehicles from Paris to Amsterdam and back has involved much labour and difficulty in bringing to a successful issue. At one time it seemed as though the idea of such a competition would have to be abandoned, owing to the difficulties in selecting the routes and the generally indifferent nature of the roads in Belgium. However, thanks to the indefatigable labours of the Committees, roads were repaired in places, and arrangements for accommodation, stores, supplies, repairs, &c., made. In the early stage of the idea it was proposed to race to Amsterdam, but clearly a race in the ordinary acceptance of the word was out of the question, as being not only attended with considerable risk in consequence of the state of the roads, but it was also at variance with the legal regulations obtaining in many towns as to the speed of vehicles, these regulations being much more drastic in Holland and Belgium than in France, and also extremely primitive in their character. Thus the question of what constitutes excessive speed is not determined by the number of units of length passed over in a unit of time, as with us, but by comparison with the performances of a local cart-horse. Thanks, however, to the influence that the two Clubs were able to exert in high places, the local authorities considerably relaxed their regulations and in other ways facilitated the success of the competition. It was found, too, that while many automobilists were desirous of participating in the competition, yet they were not disposed to indulge in racing; hence the competition was resolved into two parts—the one comprising those who wished to cover the ground in the least time, and the other those who desired to make it a tour. In the first (that is, for the race) there were 62 entries, and in the second (for the tour) there were 32.

The vehicles entered were divided into three separate classes, and these were subdivided into groups. Class A was for vehicles entirely propelled by mechanical means, and having at least seating capacity for two people. This class included three groups, the first being those vehicles having a seating accommodation for two persons, the second those seating four or five persons, and the third those carrying six or more persons.

Class B comprised motocycles. These vehicles had to be mechanically propelled, with or without the adjunct of muscular effort; the weight empty, without passengers or stores, being limited to 200 kilos = 440 lbs. In this class there were four groups: the first including motocycles weighing less than 220 lbs. empty, and fitted for one passenger; the second, motocycles also weighing less than 220 lbs., but fitted for more than one passenger; the third, motocycles weighing from 220 to 440 lbs., and carrying one person; and the fourth for motocycles of this weight, but fitted for carrying several persons.

Class C comprised those vehicles which could not be included in the two previous classes.

Such a great distance between the two capitals necessitated the race, or, more correctly, the procession, being divided into stages; the programme finally arranged was:—Leaving Paris on July 7th, the first stage was Champigny, Villiers, Jorsequy, Coulommiers, Montmerail, Champaubert, Epernay, Reims, Rocroy, Fermoy, Givet, Giergnon, Ardenne—distance, 199·6 miles. The second stage, on July 8th, was Ardennes-Nymèque, a distance of 165 miles. The third stage, on July 9th, was Nymèque-Amsterdam—distance, 68·5 miles. The fourth stage, on July 10th, included excursions in the neighbourhood of Amsterdam, but on this date the first stage for the return journey was arranged—it was Amsterdam-Liège—distance, 179·0 miles. The sixth stage was, on July 11th, Liège, Luxembourg, Verdun—distance, 164 miles; and on the 12th the final stage was Verdun, Chalons-sur-Marne, Melun, to Paris (Porte Maillor)—distance, 193 miles, the total distance being 943 miles corrected.

The following table contains the particulars of the vehicles arranged according to their classification. The first part relates to the vehicles entered for the race, and the second part those which were entered for the tour:—

Unlike the Paris cab trials, the present competition possessed little of interest to the constructor, although it must be admitted that the successful accomplishment of such a long and trying journey is a valuable test of endurance and good workmanship. Several of the vehicles had been specially built with a view to breaking the record, and were fitted, as will be seen by a reference to the accompanying table, with exceptionally powerful motors. The roads were generally of an inferior description, especially near the French frontier, and not a few accidents resulted in consequence of this.

Possessing, as we say, but few features of technical interest, it is not our intention to describe each day's proceedings or to analyse the performances of the various vehicles. The net results are contained in the following table, which refers entirely to those vehicles taking part in the race:—

Order of arrival.	Official number.	Net time corrected.	Mean speed.
Class A—		h. m.	m.p.h.
1	1	33 04	26·82
2	3	33 25	25·74
3	11	34 8	25·2
4	6	34 58	24·66
5	14	35 19	24·36
6	4	35 45	24·00
7	19	36 20	23 64
8	21	38 26	22·38
9	49	38 41	22·20
10	17	39 30	21·60
11	50	43 58	19·56
12	2	46 50	18·48
13	8	48 58	17·58
14	47	52 30	16·38
15	51	57 27	14·94
Class B—			
1	69	39 36	21·78
2	43	41 20	20·82
3	39	52 42	16·32
4	41	54 19	15·84
5	27	58 51	14·64
Class C—			
1	29	50 14	17·16
2	71	54 3	15·84

It will be seen that the speeds attained were really very high, the highest being more than twice that allowed by the British law, while the lowest is also higher than is permitted by the latter.

The following is a list of the winners in the race, together with the amount of the prizes:—

CLASS A, GROUP 1.—*Vehicles carrying two or three persons.*

It was a condition for obtaining a prize that competitors in the race should attain a speed of, at least, 15 miles per hour for ordinary vehicles, and 12 miles per hour for motocycles.

There were the usual crop of accidents, but nothing really very serious or involving any personal injury. One or two vehicles received damage through collision. One was upset in a ditch, and the contents of the petrol tank igniting set fire to the vehicle. A rider of a motocycle, by a curious mischance, steered his machine into a horse-pond and fell off; his machine pursued its course and emerged at the other side, being, however, captured before doing any harm through being out of control.

As usual the wheels gave the most trouble. Many vehicles suffered from insufficient axle surface and had hot bearings, others had trouble with their tyres, especially if these latter were solid. Of all the vehicles fitted with solid tyres, but one, we understand, succeeded in accomplishing the whole journey, this was No. 118, which was a large vehicle carrying six persons, and weighing upwards of 3,300 lbs., its mean speed was 16·7 miles per hour. It gained the prize in its class, and ran most successfully; it is fitted with that kind of tyre known as the "Ideal" in this country and as the "bande Kelly" on the Continent.

As an interesting fact it may be stated that more than 3,200 gallons of petrol, costing 22,500 francs, were consumed during the competition. On the whole the race must be considered a satisfactory demonstration of the speed and staying qualities of well-built vehicles. In the present state of public opinion, both in France and England, as regards speed it must be confessed that the results of the Paris-Amsterdam-Paris race were of a negative character as such speeds as were attained are in most places illegal. Perhaps the most useful information disclosed by this race is the great improvement that has taken place in matters of detail. The machines are much more reliable and easier to manage and under better control than those of earlier models.

As will be seen, M. Marcellin, the well-known rider, was the winner in the class of motor-tricycles. We understand he used the new Dunlop motor-cycle tyre, and went through the whole journey without a single puncture.

The Flash-Point of Petroleum.—At the recent meeting of the London County Council the Public Control Committee reported at length upon the reference from the Council as to the prevention of petroleum lamp accidents. They agreed with the recommendation of the Select Committee upon the subject, and urged that the Government should introduce during the present Session a short Bill for raising the flash-point named in the Petroleum Act of 1879 from 73° F. to 100° F. (Abel close test). This was, however, adjourned, as the Home Secretary had stated in the House of Commons that he was not yet prepared to introduce any fresh legislation without full consideration.

New Russian Oil Company.—The Baku Russian Petroleum Company (Limited) has been registered, with a capital of £1,500,000, divided into 75,000 preference shares and 75,000 ordinary shares of £1 each. From the Company's prospectus it appears that of the share capital a present issue of 650,000 preference shares and 650,000 ordinary shares is offered to the public for subscription. The Company is formed to purchase and amalgamate as going concerns and to further develop the petroleum properties owned by Messrs. G. M. Arefelloff and Co. and Messrs. Boudagoff Brothers and Co., and situated in the Baku district of Southern Russia, in the townships of Sabunchi, Balakhany Romany, and Bibi-Elbat, and at Pouta, Bulbuli, Kerged, Bina, Karadi, Khirdalan, in the same neighbourhood, and at Sundzbensky, near Crosney. The properties of Messrs. Arafelloff and Co. cover an area of about 160 acres, excluding surface leases, of which a large proportion is freehold, and the remainder leasehold. Messrs. Boudagoff Brothers' properties cover an area of 100 acres, freehold. The oil is mainly obtained by pumping, but it is said that during recent years fountains have spouted from time to time on the properties, and fountains, if continuous, must greatly augment the yield. In addition to the oil lands, the Company will acquire pumping stations, reservoirs, pipe lines, storage tanks, buildings, and three refineries, the details of which are set out in the reports accompanying the prospectus.

2 M

THE PARIS MOTO-VEHICLE EXHIBITION.

This exhibition, held under the auspices of the French Automobile Club, was undoubtedly the most successful and comprehensive that has yet been held in connection with the automobile industry. Former exhibitions of motor-vehicles both in England and in France have been sadly lacking in completeness and have not been sufficiently representative. The present exhibition was in every respects what such a display should be. It was well organised and admirably managed and was in short thoroughly representative of the most modern developments in automobilism. We do not attempt to describe it in detail, as rapid and hasty descriptions of complicated mechanism are of but little use to anyone unless accompanied by drawings. It is sufficient to say that all or nearly all the leading Continental makers exhibited numerous examples of their skill; and a very fine collection of motors and vehicles was on view. While there is no great development in the methods of obtaining power for propulsion, yet there is a very noticeable advance in the direction of improved design. The mechanisms generally have less of a "toy" or model-engine look, and are better finished. Thus cams are correctly formed, as are the teeth of spur wheels. Axle bearings, too, have larger surfaces; the means of lubrication are also better. In brief, great improvements in small but important details are the characteristics of this exhibition of motor-vehicles. It was very rightly insisted upon by the organising Committee that only practicable vehicles should be shown, *i.e.*, each vehicle had to be practically tried before it was accepted; thus the visitor had the full and comforting assurance that he was examining real working vehicles. Of the four agents used as prime movers—hydrocarbon spirit, *i.e.*, petrol, hydrocarbon oil, *i.e.*, petroleum, electricity, and steam—the far greater number of motors employed the first. As is well known the spirit motor is the favourite on the Continent, and the light and inflammable spirit employed is used with a most remarkable immunity from accident. Electricity comes next, and as is well known to our readers this motive power has been selected for the Paris cab services. Steam is extensively employed in country districts for heavy automobilism, and such firms as Scotte and De Dion, having their hands free as regards weight, have produced some splendid examples of heavy road vehicles. Petroleum oil motors are hardly used at all either in France or England for vehicles. We observe that few, if any, British firms were represented. This, no doubt, can be explained by the impossibility of manufacturing vehicles for Continental use, the high tariff effectually shutting out British motor-vehicles, as they do so many other articles of British make. In conclusion we must congratulate the Automobile Club of France upon the most complete and instructive exhibition of automobiles yet held.

The Paris Cab Competition.—With reference to the very full report of this, which we were glad to be able to place before our readers in our last issue, we think it only right to state, and we do so with much pleasure, that we were very largely indebted to our excellent contemporary *L'Industrie Electrique*, of which that distinguished engineer and automobilist, M. Hospitalier, is the director. It was by a pure inadvertence that we did not make this acknowledgment in the body of our report.

BROWN'S MOTO-VEHICLE.

Mr. W. H. Brown, of Devizes, is well known as an enthusiastic and successful automobilist, and has designed and built more than one vehicle. Gaining experience he has improved upon his previous designs, and his latest model we illustrate in the accompanying drawings. As will be seen, the vehicle is a kind of steam wagonette with seating accommodation for four persons, but contrary to usual practice the machinery is kept in the rear, and is cased in, so that any noise from the gears or oily smell from the engine is reduced very considerably. The present form of carriage is the outcome of considerable time and experiment. The passengers are seated sideways, which has the advantage of being more sociable and enables the driver to get a good view of the road behind as well as in front, and this in crowded traffic is most important. The boiler is of the vertical multitubular type, oil fired; it works at 150 to 200 lbs. per square inch, and steam can be raised from all cold to 150 lbs. in 18 minutes after lighting.

The engine has two high pressure cylinders, each $2\frac{1}{4}$ inches

Fig. 1.—Brown's Steam Moto-Vehicle.

diameter by 3 inches stroke, and is fitted with link motion reversing gear, and when the car is started is adjusted to cut off the steam at about $\frac{3}{4}$ stroke. The engine runs at 312 revs. per minute, and drives the car at 12 miles per hour. Two speeds are fitted, and although more might give a slightly higher average speed, Mr. Brown does not think it would compensate for the extra weight and complication.

The engine drives direct through the two-speed gear on to the jack-in-the-box gear which transmits the power through pitch wheels and chains to the road wheels, which are of wood, and fitted with solid rubber tyres. The car is fitted with two powerful band brakes and two tyre brakes, beside which the reversing gear is an excellent emergency brake.

The oil tank holds about 12 gallons of oil, and the supply of water is equal to a run of about 18 or 20 miles on an average road. The working expenses are about a penny per mile.

A most important feature in a steam-car is that when the car is stopped the engine is at rest also, thus avoiding the vibration so apparent in oil motor-vehicles. Mr. Brown finds that an average speed of 10 to 12 miles per hour can be maintained on an average road without any difficulty.

THE PARIS CAB COMPANIES.

THE Paris correspondent of the *Financial Times* of the 18th ult. gives the following particulars of the two best-known cab companies in Paris, viz., the Compagnie Générale and the Urbaine. Both of these are very big concerns, whose shares are dealt in daily on the market. The first named, the Compagnie Générale, is in a fairly prosperous condition, and the net profits for 1897 were higher by nearly £14,000 than those of the previous year. The dividend declared at the last general meeting was at the rate of 28 francs 80 cents. per share. The 500 franc shares are at present quoted at 837 francs, so that the dividend represents a little over 3 per cent. The Company owns 8,246 cabs, which are valued at 596 francs each, or just under £24; and 12,166 horses, priced at 300 francs, or £12, each, though, of course, they cost more than that to the Company. The cost of horse keep is 1 franc 26 cents. per day per beast, and, says the writer, the poor beasts do not look very fat on what they get. The Company possesses land and buildings valued at 30,368,052 francs, or over £1,214,000. Its capital, according to the last accounts submitted, amounts to 29,456,000 francs, or £1,178,240, plus a debenture capital of 16,257,000 francs, or £650,280, and it possesses a reserve fund of over 4,761,000 francs, or £190,440. Its outstanding liabilities do not exceed 5,500,000 francs, whilst the total net profits for 1897 were close on 2,000,000 francs, or £80,000. The directors have been experimenting considerably during the past two years, with a view to adopting motor traction for all their cabs. After various experiments the directors have now secured what they believe to be an almost ideal electric motor, which, it appears, gives the most excellent results. Before, however, adopting it altogether, the directors are having 100 cabs fitted with the new motor, and if, as they expect, the results are satisfactory the whole of the Company's rolling stock will be transformed by the year 1900 and horse traction done away with. Considerable capital will, of course, be required to effect this, but the directors can obtain it without difficulty by the issue of debentures and by the sale of a considerable portion of their property, which, under the altered circumstances, would not be of further use. Then, again, the amount annually spent in the purchase and keep of horses will be at their disposal. At the last general meeting the shareholders gave the directors authority to issue debentures for this purpose to the extent of 10,000,000 francs.

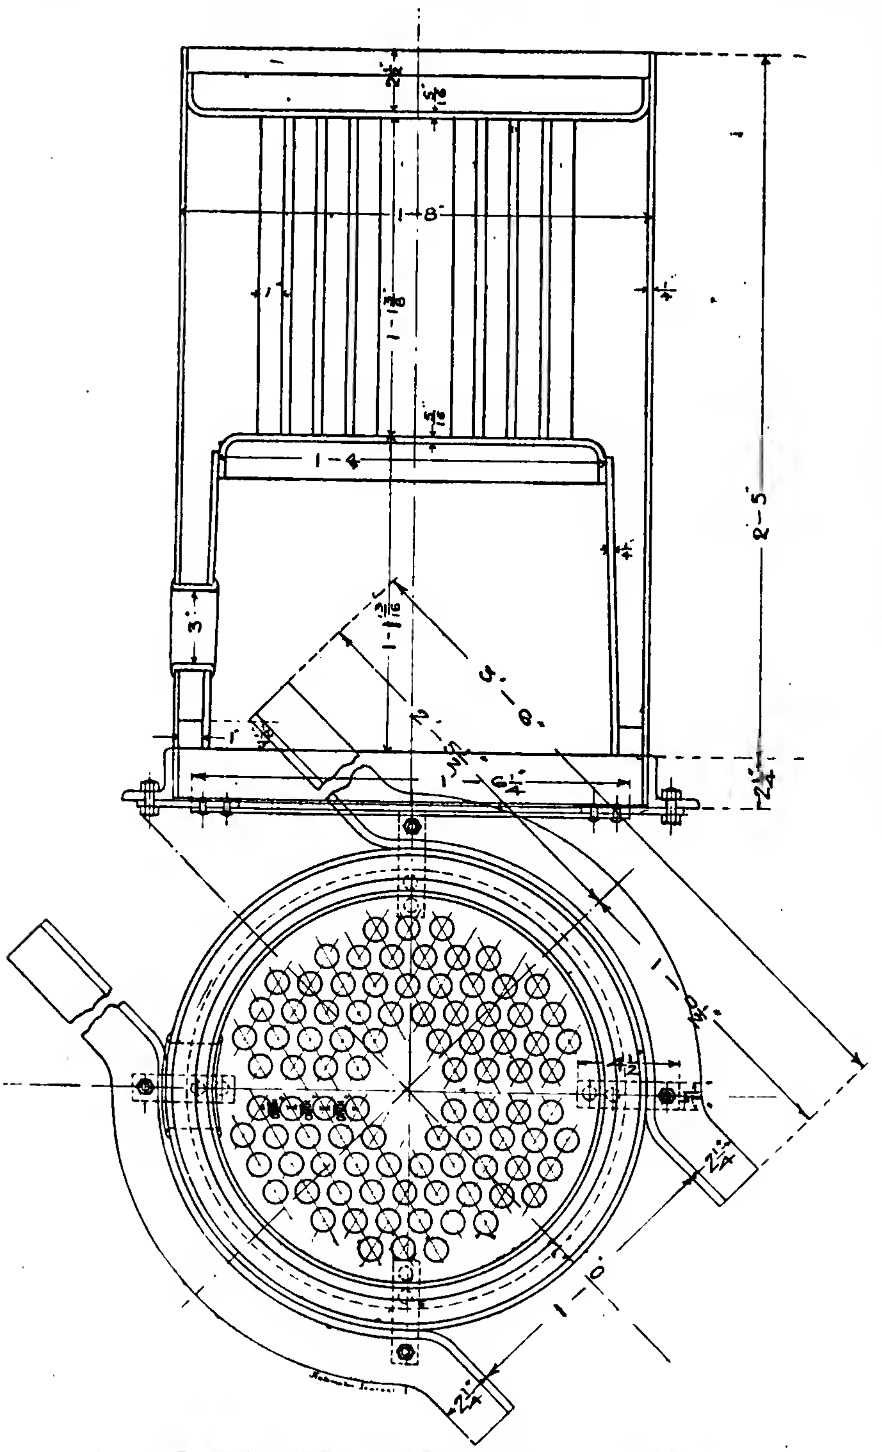

FIG. 2.—BROWN'S STEAM MOTO-VEHICLE (Elevation and Plan of Boiler).

negotiations fell through.

As a result of its display at the recent Exposition of Automobiles in Paris, the Hartford Manufacturing Company, of Connecticut, has, we are glad to say, secured an order for eight electric carriages.

AUTOMOBILISM IN FRANCE AND ENGLAND.

The following is a translation of a letter lately written by Sir David Salomons, Bart., President S.P.T.A., to M. Paul Giffard, editor-in-chief of *Le Velo* :—

Dear Mr. Giffard,

I am certain that your nation will not hesitate to recognise that few people are so well disciplined, and demand less administrative tutelage, than the inhabitants of Great Britain.

I have observed this fact on several occasions, which the French newspapers relate with surprise, that the police are commended by all the English people; equally so, the fact that a word or gesture of a policeman suffices to keep all classes of people in order. All this is due to our laws and the kind of education we receive.

In France the Government does everything for the people. It controls their hospitals, organises popular fêtes by means of subsidies, protects every branch of trade that seems feeble—in a word, assists the French as if they were quite unable to walk alone.

In England the citizen is given up to himself and does not receive from his Government either assistance or encouragement. It is then very natural that from his earliest infancy he learns to be independent; thus, later on, he possesses confidence in himself and the necessary initiative for the battle of life. This explains why with us each individual does his best to maintain order instead of waiting for others to maintain it for him. But you will say, where do these remarks come in in the question of rules concerning the movements of automotors in France? Yet these things are connected in a very evident manner.

In England there are certain rules that you know of as well as I do, limiting the weight of vehicles and many other details, with the sole aim of preventing the automotor-carriage from becoming a public danger. Thus it is that in case of accidents the owner is liable for damages without prejudice to any previous penal system. Under these conditions nobody in England would think of putting on the road a vehicle that was in any way dangerous, much less to confide the direction of a carriage to a conductor who was not perfectly experienced. Apart from that we are absolutely free in all that concerns the new mode of locomotion; no examination is necessary and no conductor's permit is required.

In France, on the contrary, most absurd restrictions are imposed on the public both with regard to carriages and conductors. The English method is much preferable for this reason, that it is the individual possessor who directs an automotor who is considered responsible for the security of the public, whereas in France the system of examinations and permits take from the individual this responsibility up to a certain point.

In reality, the examination of carriages is absurd the instant it is not made each time the vehicle leaves the coach-house; it is thus necessary for an engineer in connection with the prefecture to be appointed to survey each departure of a carriage. You will soon see where that will end.

As I have all my life been used to driving horses, I can by experience personally certify that it is easier to drive an automotor than to hold in a "noble beast." Moreover, no difficulty is made in France with drivers, although, to be logical, each carriage and horse should be examined, considering that a "horsy" accident is much more serious than an automotor accident. The number of people killed or injured by horses every day in London is considerable, but probably it has been thus since the beginning of the century and we do not pay much attention to it here. Is not the title "Noble Beasts," inaugurated by the *Velo*, instructive?

I well know it will be remarked that the number of carriages drawn by horses is very much more considerable than that of automotors, but this seems to me the best argument in favour of much more liberty for the new vehicles. At the commencement of railways accidents were much more frequent than at the present time, although the number of passengers has increased enormously. Thanks to this fact no ridiculous restrictions have been enacted.

It is to be hoped it will be the same with automotors, and I feel convinced that before many years have elapsed the fear of carriages without horses, by which some people are affected, will have disappeared, and that accidents will be very rare. This is the idea which guided our legislators when the new law with regard to the regulation of automotor traffic in England was voted by Parliament.

I trust you will interpret my remarks in the spirit in which they are written, that is to say, not as a critic of French customs, but as the ideas of a man who has much respect and affection for the country who has given to the world many, if not all, the lessons of civilisation, and which can be considered as the cradle of art in modern times.

Yours very sincerely,
David Salomons.

THE ACETYLENE EXHIBITION.*

At the official opening of this exhibition in the East Conference Hall at the Imperial Institute, London, Major-General Sir Owen Tudor Burne, G.C.I.E., K.C.S.I., the chairman of the Council, presided, and was supported on the platform by Sir Frederick Abel, K.C.B., F.R.S., Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Professor Vivian B. Lewis, Mr. Boverton Redwood, F.R.S., Professor J. M. Thomson, LL.D., F.R.S., Sir Robert Herbert, Sir Henry Trueman Wood, M.A., and other gentlemen.

Addressing the fairly large assembled company of Fellows of the Imperial Institute and their guests, the Chairman, in a short and pithy address, narrated the history of the present exhibition, which was initiated on the suggestion of Sir Frederick Abel, who, feeling assured of the growing commercial importance of acetylene, and being cognisant of the mystery attaching to the illuminant in the minds of the general public, thought that a public exhibition of the means of generating the gas, and of its illuminating powers, such exhibition being officially and impartially conducted, would be the best means of dispelling that mystery and of showing the benefits attaching to this new gas as an illuminant. Through its secretary, Sir Henry Trueman Wood, M.A., the Society of Arts organised an acting council, of which the chairman was president, the galleries of the Imperial Institute were placed at its disposal, and the London County Council kindly lent them the use of their Testing House in Harrow Road, and also of the invaluable services of their officers, Mr. Pemberton Stubbs and Mr. Duffield. Every single apparatus in the exhibition had undergone severe, continued, and impartial test at the hands of these gentlemen before being allowed to be installed on the premises. The safety of each apparatus shown may therefore be taken as certified by its very presence in the exhibition building; its efficiency will be the subject of daily test and observation during the exhibition, and a full report thereon will be made in due course. The chairman proceeded to explain in simple language what calcium carbide is, and how on its decomposition on coming in contact with water this acetylene gas is evolved, and concluded a most interesting speech by inviting those present to accompany him through the exhibition galleries to examine the collected exhibits, and also to see the generators in actual operation in the open building erected for that purpose in the grounds.

According to the regulations which have been prepared by the committee, the generators are classified under three heads, namely: (1) Those in which the gas is generated by water being allowed to drop or flow in a small stream on to the top of the carbide; (2) those in which the water rises around the carbide; and (3) those in which the carbide falls into the water. Further sub-divisions are made in relation to automatic and non-automatic generators. The term "automatic" covers those generators which have a storage capacity for gas less than the total volume which the charge of carbide is capable of generating, and which depend upon some special contrivance for stopping contact between the water and carbide when the consumption of gas ceases. The term "non-automatic" includes those generators in which a holder of sufficient capacity is provided to receive the whole of the gas made from the largest charge of carbide which the apparatus is capable of taking.

The rules which govern these sub-divisions are :—(*a*) in the automatic types the pressure must not exceed 100 inches; (*b*) when the apparatus is first charged the air in the generating chamber must not exceed one-fifth of the capacity of the apparatus; (*c*) the generation of gas to be speedily arrested when closing the outlet-cock; (*d*) the decomposition of the carbide not to give rise to excessive heating. To the non-automatic generators sub-sections (*a*) and (*d*) also apply, and, in addition, it is provided that the air space in the generating chamber should be as small as possible, and that in the event of the delivery pipe from the generating chamber to the holder becoming choked the gas can escape either by blowing a

* Unavoidably held over from our last issue.—Ed.

seal or by driving back feed-water end escaping through the tank. All the generators sent in were tested hy the London County Council, and only those which passed the test were admitted to the exhibition. There are two sets of exhibits, one of which comprise apparatus, which is shown at rest in one of the galleries, whilst the other embodies generators shown in operation in a specially-erected building located in the grounds, the gas produced heing utilised in an adjoining gallery.

Pressure on our space forhids us to do more than give a brief enumeration of the various exhibits. Among these, however, are many worth inspection, tho principal exhibits being as follows:—

The International Industrial Syndicate show the Buffington system of acetylene generator. This consists of a carbide holder, above which is a water tank fitted with an automatic valve, both heing attached to and connected up with the gasholder. Water is allowed to trickle on the carbide, and the gas on being formed passes into the receiver. As the gasholder rises the water is automatically cut off, and as the gas is consumed water is admitted to the carbide chamber, and the generation of gas recommences.

The British Pure Acetylene Gas Syndicate exhibit a generator invented hy M. Pistel. This generator is easily manipulated and is of simple yet efficient design. Messrs. Thorn and Hoddle, of New Tothill Street, Westminster, have an installation especially suitable for those engaged in photographic work. The Midland Acetylene Syndicate show an automatic generator which only is in action when the gas is required. Messrs. Exley and Co., of Huddersfield, also have a good automatic arrangement in their generator. The Calcium Carbide Company, of Cheapside, show en excellent plant, very suitable for country houses. The Lines Acetylene Gas Company, of Dale Street, Liverpool, have a varied display of generators and apparati.

The Acetylene Gas Corporation, of 100, Queen Victoria Street, London, exhibit Fourchotte's Generator and Holder; the latter consists of a bell-shaped cover, arranged so as to rise and fall when the volume of gas is increased or diminished in proportion to the consumption.

Another good type of generation, that known as the "Beacon,' which is being placed on the market by the Acetylene Beacon Light Company, of Colmore Row, Birmingham. The "Beacon" generator does not require frequent charging; the carhide chamber is made to hold from 30 to 1,000 lhs., and it may therefore be left to take care of itself for several months at a stretch if desired. Another point is that there is plenty of cooling surface, and the tank is enclosed, which prevents the gas overflowing or smell arising from the water.

Another very simple and efficient generetor is that known as the "Thornton-Scarth," which is heing manufactured hy the Thornton-Scarth Automatic Lighting Syndicate (Limited), Vittoria Street, Birmingham. This generator seems to fulfil most of the essentials of a perfect acetylene gasometer, it being a simple, safe, end automatic apparatus. The user has simply to keep the generator supplied with cerbide and water, the rest is automatically done. The gas is produced under the perfect control of the floating holder. If the gas is generated too fast, the holder rises and cuts off the water supply. Then as the gas is used up the holder slowly falls, allowing the water to again drop upon the carhide and so continue the creation of gas.

An ingenious automatic generator is that of Sir Charles Forbes. This consists of a cistern which is filled with water to a given level. The water is admitted to the gas bell, and rises until it reaches a small orifice hored in an inner vertical tube, whence it drops into a cone and is conveyed to the carbide, which is placed in a drawer beneath, therehy liberating the acetylene.

Mr. C. Crastin, of 16, Tollington-road, Holloway, London, shows a very practical generator, which is automatic in its action. There is a carbide chamber on each side of the gasholder, and water is fed in until a given quantity of gas is made, when it is shut off until it is again required, when the supply is automatically turned on. The main features of this generator are small storage space, uniform pressure, and no overflow of water, while the cost of working is a minimum. This plant struck us as heing very neat and compact.

Mr. R. Lucas, of Westcombe Hill, Blackheath, showed an acetylene motor bicycle, but the method employed was not very apparent, and no one was present on the occasion of our visit to explain it. No doubt we shall hear more about it in time.

The exhibition, as a whole, was very successful, and has done much to extend the use of acetylene as an illuminant.

AN ELECTRICAL DIFFERENTIAL GEAR.

At the recent meeting of the Physical Society Professor Carus-Wilson (whose work on electric traction was lately reviewed in The Automotor) exhibited an apparatus to illustrate the action of two electric motors, coupled in such a way as to admit of their rotating at different speeds. The two shafts are placed in line, and each is fitted with a hevel wheel, gearing into an intermediate wheel. The axis of the intermediate wheel is at right angles to the line of the motor shafts, and is free to rotate in a plane at right angles to that line. The motors can be made to rotate at different speeds hy altering the strength of the magnets of either or hoth. The motion of the intermediate wheel depends upon the difference of the two speeds, or upon their mean, according to their relative directions of rotation. A simple graphic construction enables the action to he predetermined for any given load on the intermediate wheel. Calling the two motors A and B, and the intermediate wheel C, lines can he drawn on a base of current to represent the speeds and the torques for each motor. If the motions of A and B are in the same direction, the load or torque is the same on each, and of similar sign. Hence, as the load on the wheel, C, is increased, the speeds of A and B tend to become equal (if A had been running faster than B), and for a certain load on C the speeds of A and B will be equal. If the load on C is further increased, B will run faster than A. Also, there will he a certain value for the load on C, at which the motion of A will reverse. A further increase of the load on C will bring C to rest, A and B then rotating at equal speeds is opposite directions. When the load on C is nothing, let the motors rotate in opposite directions, A running faster than B. The motion of C now depends upon the difference of speeds of A and B. When a load is put on C, the motion of A is retarded, while that of B is assisted, hence B takes less current, and A takes more. The torques on the two motors, due to the load on C, are now of equal amount, but of opposite sign. As the load on C is increased, the speed of A is reduced, and that of B increased, until the two are equal, and C comes to rest. B is now acting as a generator, and sending current into A. If the load on C is simply that due to friction, the process cannot he carried further. But if the load on C is reversed the speed of B becomes greater than that of A, and the motion of C is reversed. In the steering gear designed by the Union Electricitäts Gesellschaft, the intermediate wheel is made to actuate a rudder hy differential action. The motion is reversed hy making the speed of one motor greater or less than thet of the other.

AUTOMOBILISM IN AUSTRIA.

A correspondent of the *Morning Post* writes from Vienna:—Though the interest in motor-cars in Austria is relatively slight, the various touring clubs are seeking to make them popular. An Austrian Automohile Club has been formed, and in conjunction with the Austrian Touring Club it has arranged an International Automohile and Bicycle Tour through the South Tyrol for the latter half of this month. Seeing that the track lies over the Stilfserjoch, along one of the highest roads in Europe (2,814 metres above the sea level), the ride will not only be a test of endurance but of the relative qualities of the various makes. The competitors will proceed from Sulden, hy way of Trafoi, Meran, Bozen, and Toblach, as far as the Strada d'Allemagna, and thence over the Strada d'Ampezzo to Cortina, crossing the Austrian frontier at San Vito, returning to Austrian territory near Monte Croce Pontet, and ending their journey at Penegal, near Bozen. Controlling stations will be established along the entire route with the object of avoiding any undue strain on the part of the competitors. From a military point of view the undertaking is not without importance. The Tyrol is not too plentifully hlessed with railways, and the hicycle and the motor-car will now demonstrate the possibility or impossibility of the passage of traffic along the mountain routes and through the passes of Austria. As a direct consequence, it is not unlikely that the tour will stimulate the movement for the construction of strategic routes throughout the whole of Western Austria.

MUNICIPAL AUTOMOBILISM IN HACKNEY.

At a recent meeting of the Hackney Vestry (a somewhat progressive body in some respects, but hopelessly unenligbtened on automobilism) Mr. Yarrow Baldock proposed a motion to the effect that considering the large and increasing amounts paid by the Vestry for horse-hire and cartage, and with a view to facilitate the work of slopping and dusting being undertaken entirely by the Vestry without the intervention of a contractor, it be referred to the General Purposes and Sanitary Committee as to the practicability and possible economy of employing for the purposes of the Vestry carts and vans driven by electrical or other automatic motors; as to the advisability of fitting suitable motors to the water-carts and other vehicles, all or any, at present the property of the Vestry; and as to the advisability of the purchase by the Vestry, for experimental purposes, of a motor-van or vans of the most approved pattern designed for the collection of refuse and scavenging, either or both. Mr. Richmond contended that Mr. Yarrow Baldock was very premature. They had not even got their electrical station, so he should like to know if they did get these motors where they were going to get their electrical supply from.

The Vestry agreed with Mr. Richmond, and adjourned the consideration of the matter for another year.

It has not occurred to these opponents of economical administration that they are wrong in their premises and deductions. A central electric-light station is by no means a necessity for a service of, say, half a dozen electric motor-vehicles, such as would be used by a Vestry.

Assuming, for the sake of argument, that such a vehicle would consume per day of 9 or 10 hours 10 kilowatts—this is really an outside figure—then it is easily seen that a gas or oil motor of 8 B.H.P., working 10 hours per day, would supply all the necessary current. The motor and batteries could be placed in any ordinary stable, and no expensive fittings would be necessary. We trust Mr. Yarrow Baldock will not be disheartened in his praiseworthy attempt to instruct his colleagues in this matter.

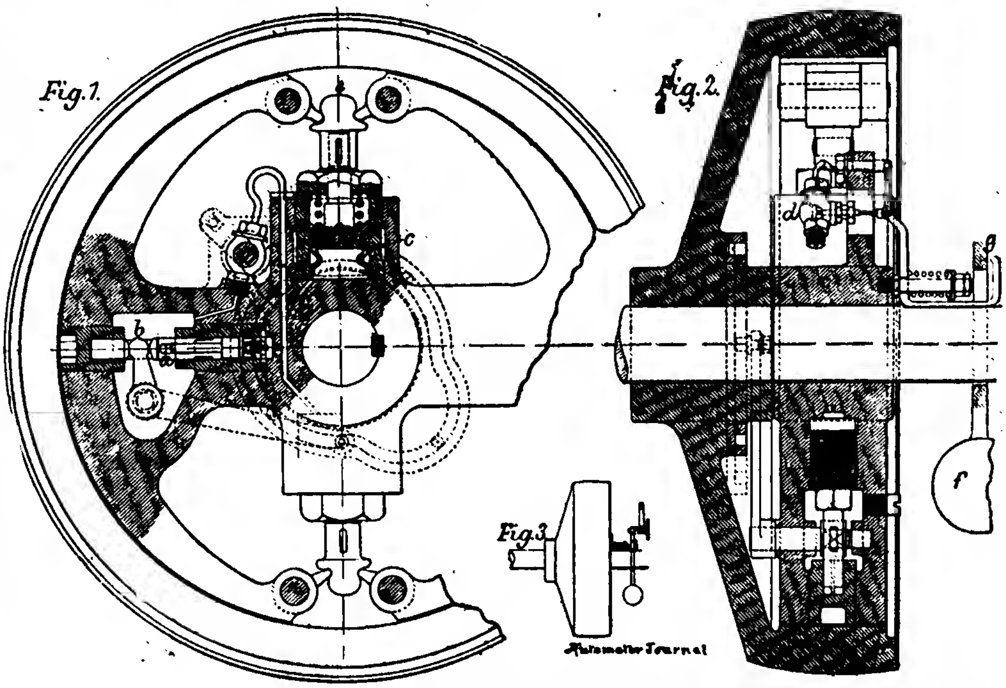
Lights for Vehicles: County Council Bye-law.—In the new bye-law passed at the recent meeting of the London County Council it is provided that every carriage, cart, wagon, or other vehicle which shall be driven or be upon any highway during the period between one hour after sunset and one hour before sunrise shall be provided with a lamp or lamps, which shall be so constructed and placed (such lamp or one of such lamps being on the right or off-side of the carriage, cart, wagon, or other vehicle) as to exhibit a white light in the direction in which the vehicle proceeds, and shall be so lighted and kept lighted as to afford adequate means of signalling the approach or position of the vehicle. This bye-law shall not apply to any carriage which is required to carry lights by any statutory enactment, or by any rule, regulation, or order made under any statutory enactment, and for the time being in force.

HERSCHMANN'S HYDRAULIC CLUTCH.

Although there are a great number of friction clutches in the market everybody who has had experience with such pieces of mechanism knows that they are often found troublesome after little use, and will "slip and heat" when required to engage, and "grip and bite" when required to be out of gear.

Nothing more positive acting than a hydraulic means of operating such pieces of mechanism could well be devised, and with this end in view Mr. A. Herschmann, of 1, Bexley Road, Erith, has designed a clutch which we illustrate herewith.

As will be seen, the engagement is automatic, *i.e.*, the driving side *itself* engages its companion by actuating a little force-pump of simple design, which, as long as there is relative motion, or even slip only, between the two halves, forces oil under leather cups, inflating them like a pneumatic tyre, until they press sufficiently on the toggle joint and so expand the inner parts as to grip the outer half firmly, when pumping action ceases and a most powerful engagement is maintained.



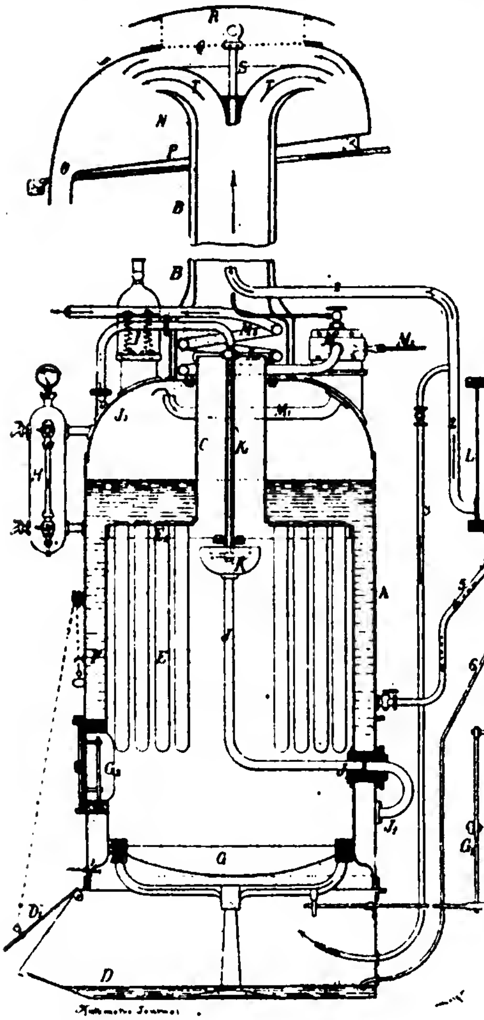
Referring to the drawings, there is an oil pump, shown at *a* (Fig. 1), the plunger of which is operated by a long cranked lever, the other end of which has a pin running in a cam groove formed in the other part of the coupling, as shown. Should the two constituents of the coupling rotate relatively to each other, this pump is worked, and drawing from the reservoir, *b*, it sends oil through a hole in its ram, closed with a valve, and delivers it into a discharge pipe. This discharge space has three branches, two of which communicate with two leather cups, of which one is shown at *c*, whilst the third branch leads back through a spring-mounted valve, *d* (Fig. 2), to the oil reservoir, *b*. Should this valve be closed, the oil is forced underneath the leather cups, and presses outwards the plungers above them. These plungers are connected by a toggle arrangement to the friction arms, as shown at *e*, thus putting the clutch into gear. As soon as this is effected, and the two portions of the clutch rotate together, further pumping action ceases. To release the clutch the valve, *d*, is opened, and the pressure in the cups being thus relieved, the friction arms spring clear of the opposing pulley surface. The valve, *d*, is controlled by the pendulum weight shown at Fig. 2 and also in Fig. 3. When this is moved away from the pulley it catches on the point, *g* (Fig. 2), and pressing it outwards, opens the valve, *d*. The pendulum normally hangs quite free of the clutch and shaft, so that there is no friction and no side thrust whilst the pulley is running. To throw the clutch out of gear a small relief valve is so arranged that when pulled from its seat it releases the hydraulic pressure, and allows the oil to run back into the tank in the inner half. The disengagement, therefore, is as powerful as the engagement, being simply the reaction of the latter.

The clutch is self-contained, dust-proof, and balanced, and requires no heavy shifting levers or anchorage. A centrifugal weight is arranged for special cases which disengages the clutch when a maximum and adjustable speed limit is exceeded.

The clutch is made by Messrs. Alldays and Onions, of Birmingham.

THE SCOTTE MOTO-VEHICLE.

We have in previous articles described the salient features of this very successful type of motor-vehicle. On the present occasion we



The Scotte Boiler.

propose to describe the later improvements that M. Scotte has made, and more particularly his boiler. In the Scotte omnibus, numbers of which have been running in various parts of France with uniform success, the driving wheels are behind, the steering wheels in front, and the intermediate shaft parallel to and between the two axles.

The boiler and engines are in front of the compartment for the passengers, the driver's platform is between the two latter, so as to leave his view unobstructed and to place him close to the various controlling levers. The available space is carefully parcelled out and utilised for coal, tools, oil, &c. Water is carried in two tanks, placed under the seats of the passengers, fore and aft.

The boiler is of the "Field type," and supplied with feed-pump and injector; a recent modification makes it possible to lower or raise the fire-grate for the purpose of keeping fire low when at rest; a rotary movement may also be imparted to the grate disc for the purpose of cleaning it.

Ashes may be damped with the condensed steam from the feed-heater, which entirely prevents the scattering of glowing fuel on the road. This is a matter which we would particularly call the attention of constructors to, as hot ashes on a road would cause much harm to horses and pedestrians. It is by a careful attention to these details that much of the success of M. Scotte is due. He, in his design, does all he can to avoid possible objections.

The boiler has a cylindrical shell dished at the top, to which latter is attached the double-barrelled funnel; it is vertically traversed by the uptake which conducts the burnt gases into the chimney. Below this shell is the ashbox, which has handholes giving access for cleaning.

The well-known Field tubes, which are of the priming or quick-generating type, are suspended from the crown of the firebox, which latter accommodates the circular grate at its connection with the main shell of the boiler.

The grate has fixed as well as jointed firebars, the latter, when rocked by means of a hand lever, effectually prevent clinkering.

A circular band is arranged over the grate so as to protect the rivet heads and the seams from being burnt by the flames.

The usual gauge glasses, pressure gauges, and safety valves are conveniently fitted on the top of the boiler. A water circulator, an exhaust-heater, and a superheater are also provided. The former consists of a strong pipe coupled to the annular water space at the bottom of the boiler, from here the pipe starts and returns with a double bend (so as to leave the connections outside) into the firebox, rising centrally and vertically amidst the Field tubes, and returning and delivering into the crown of the boiler. Where this circulator pipe passes through the uptake a suitable cup protects its joint; the latter, being suspended from a cross on the top by means of screwed rods, allows of adjusting the draught by lowering or raising.

The cup, of course, acts as a deflector, and leads the upgoing gases off and around the Field tubes.

The feed-heater is also intended to act as a water softener; it is simple and easily inspected, and we may add that the exhaust steam from there goes into the chimney, and the condensed steam into the ashbox, a bye-pass pipe branches off from the chimney connection and allows of blowing the fire to vary the draught. Superheating is effected in a coil exposed to the hot gases before they enter the chimney.

The emission of sparks is prevented by bending down the top of the chimney and making it bell-mouthed and enclosed within another protecting hood which has a sloping bottom, wherefrom the cinders drop in a fall pipe and into the ashbox. It will be seen that great attention has been given to these details, many of which exhibit great ingenuity. In conclusion, we congratulate M. Scotte upon the great engineering skill he has displayed in perfecting the motor-vehicle.

Reorganisation of the London Fire Brigade.—At the last meeting of the London County Council the Fire Brigade Committee recommended the adoption of a scheme submitted by the chief officer for the better organisation of the brigade. Captain Wells points out the rapidly-increasing strength of the brigade, and urges the appointment of another superior officer, to be styled "chief superintendent," who should be in charge of a central district to include the following stations:—Headquarters, Watling Street, Bishopsgate, Tooley Street, Waterloo Road, Scotland Yard, and Whitefriars. The "dangerous areas" are principally comprised in the localities protected by these stations, and in order to afford better facilities for mobilisation Captain Wells suggests that they should all be directly connected by telephone with the chief station. Under the new arrangement, whenever the chief officer and second officer were absent at a fire, the chief superintendent—the next senior officer—would be present to take charge, and to arrange for the disposition of men and appliances, a duty which at present devolves upon a foreman.

The Royal Lancashire Agricultural Society.—Among the exhibitors at this popular show were Messrs. T. Coulthard and Co., of Preston, who showed their motor-wagon, and obtained the Society's medal for their water-tube boiler. We congratulate Messrs. Coulthard on their success. In our next issue we hope to describe and illustrate their engines and boilers for motor-vehicles.

NOTES OF THE MONTH.

At a recent meeting of the Middlesex County Council, on the motion of the Chairman (Mr. R. D. M. Littler, Q.C., C.B.), the General Purposes Committee were asked to consider and report what steps could be taken to identify cyclists and drivers of motor-cars guilty of recklessness in the driving of their machines.

From some statistics furnished by the United States Consul at Berlin respecting the carriage pavements of that city, it would seem that wood pavement does not find much favour there. The area of pavements is 6,500,405 square yards, and of this area a little less than 74 per cent. has stone pavements, about 25 per cent. asphalt, and a fraction over 1 per cent. wood. The Consul states that the proportion of asphalt is steadily increasing. The soil consists of coarse, gritty sand, forming apparently an excellent foundation for the heavy 8-inch layer of gravel and cement over which the 2-inch covering of asphalt is spread.

On the last Sunday in July Prince Christian travelled with Mr. H. E. S. Holt from Aldershot to London on a Daimler motor-car. Mr. Holt left town in the morning, and returned with the Prince after lunch; the journey back, a distance of about 35 miles, being covered in a little over two hours. The following Tuesday Mr. Holt went down to his old school, Eton, on the same car, accompanied by the Lord Chancellor and Lady Halsbury, covering the distance there and back at a high average speed. *En passant*, we may remark that Mr. Holt had the honour of taking the first motor-car to the House of Commons last year, the other occupants being Mr. A. J. Balfour and Mr. Chaplin.

Some months ago we described a new departure in nautical automobilism—the Bazin roller boat. We predicted its failure, which duly happened. The vessel is now in Hull for sale. It will be remembered that the "Ernest Bazin" consists of a flat rectangular deck, made of steel, 130 feet long by 44 feet broad, and this rests on six huge floats or rollers 30 feet in diameter. Her boilers and engines are warranted of the very best, the work having been done by the engineers who have the French Government torpedo work. She cost £20,000, and her failure to give the results expected both in regard to speed and motion completely broke the spirit of her designer. Nearly 20 years ago the twin boat "Bessemer"—built, like the "Ernest Bazin," to overcome the effects of pitching and rolling at sea—was also taken to Hull after she had proved a white elephant.

Oil fuel was tried at sea for the first time in the British Navy at Portsmouth on the 29th ult. Some months ago the Admiralty sanctioned an experiment with the system invented by Mr. Holden, of the Great Eastern Railway, on board the "Surly," torpedo-boat destroyer, and in the interval various trials have been carried out in one of the dockyard basins. At these the chief difficulty was to furnish a sufficient feed of oil, but this has been overcome by the provision of an overhead feed tank. There are four boilers on the "Surly," two of which are still retained for coal fuel, but the others have been adapted for oil. In lighting the latter series the elements of combustion are oil and coal, but as soon as a sufficient heat has been generated, bricks replace the coal and are heated from the oil spray. At the trial no difficulty was experienced in obtaining a sufficient spray, and the heat was so well maintained that at times the thermometer indicated 150° F. in the stokehold. Three runs over the measured mile in Stokes Bay were made, and while a speed of 16 knots was hoped for, the runs gave a mean of 14 knots; but as this was only a preliminary trial, the result was regarded as satisfactory. The oil used had a flash-point of 280° F.

We have received from a correspondent a long and interesting account of a tour recently undertaken by himself and friends through North Wales in a motor-vehicle—one of those owned by the Motor Touring Company, of Llandudno. This Company seems to have more work than it can do; the popularity of its tours making great demands upon its resources. To view some of the finest scenery in the country from a well-appointed motor-vehicle is undoubtedly one of the best means of enjoying a holiday we know of. One has all the advantages of any desired speed, safety, certainty, and comfort, together with the knowledge that these are not obtained at the cost of animal suffering. We congratulate our friends, the Motor Touring Company, on the success which has deservedly attended their enterprise. We understand that the motor-vehicles used by the firm are fitted with Benz motors.

The following appeared in the *Daily Telegraph* in a recent issue:—"This season automotors have entered largely into the amusements provided at several fashionable watering-places, but the march of science in this direction has no attraction, it seems, for the inhabitants of Westgate-on-Sea. On the contrary, the invasion of the town by motor-cars has evoked many protests. At a meeting of the Parochial Committee several members urged that the private road of the Westgate Estate should be closed to the cars, which were described as an abominable nuisance. It was stated that some of the vehicles travelled at the rate of 25 miles an hour, and that the noise they made seriously disturbed public worship at the churches and chapels. One member of the committee urged that loose gravel should be sprinkled on the inclined roadways, as he believed the cars could not get over this. The committee adopted the suggestion, and decided to take legal advice as to their powers to exclude or regulate the objectionable visitors."

The Clacton-on-Sea Municipal Council is apparently not impressed with the desirability of encouraging automobilism, and so it forbids an enterprising local firm that has established a service of motor-vehicles to places of interest outside the town from enjoying the same facilities as the local cab and omnibus proprietors; doubtless these latter are large employers of labour and large ratepayers, and as such deem themselves entitled to a kind of "favoured trade treatment." They evidently possess and exert a good deal of "influence" on the local Council sufficient to cause that body to discriminate in a most unjust way against automobilists. From a letter that Messrs. Johnston and Seward, the firm who are running the motor service alluded to, wrote to the local Press, it would appear that the drivers of the motor vehicles are daily requested by visitors to pick them up on the road, and many grumble because they, the drivers, do not stop when requested to do so. Messrs. Johnston and Seward desire to make it publicly known that they are unable to pick up passengers on any of the public streets or country roads until the Clacton-on-Sea Council give them a license to do so. Why a license should be necessary is not very clear. One thing, however, is very clear, and that is the necessity for the existence of an association which will take up such cases of harshness and discrimination on the part of local interested bumbles, and determine the legality of the action of the latter in the High Court. A few lessons in common law are sadly needed by these administrators of municipal law.

A valuable and interesting Paper, entitled "Some Notes on the Disinfection and Deodorisation of Sewage with Chlorine," recently appeared in the *Journal of the Society of Chemical Industry*, the authors being Mr. E. Shrapnell Smith, Hon. Organising Secretary of the late Liverpool Heavy Trials, and Mr. Max Muspratt. The subject is well summarised and clearly set forth by the authors, and in a short space the article conveys a large amount of valuable information upon this very important subject.

DOINGS OF PUBLIC COMPANIES.

National Cycle and Motor Car Insurance.

An extraordinary general meeting of the National Cycle and Motor Car Insurance Company (Limited) was held on July 20th, at the offices, 33, King William Street, E.C., for the purpose of considering the financial position of the Company and other matters. Mr. C. H. Tindal presided.

The Chairman said he desired to put the position of the Company fairly and frankly before the shareholders. When the Company was formed the policy adopted by the directors was that in conjunction with the cycle insurance business they should do a general insurance business, because they considered that while they were getting together a cycle connection they might, by means of a carefully-managed general insurance business, obtain a satisfactory premium income to show to the shareholders at the first general meeting. When the balance-sheet was submitted up to 30th September last year, the premium income, as shown, represented £4,000 odd, and that the Board considered a very satisfactory state of things. After the meeting quite a different phase came over the business. They began to receive claims in a most extraordinary manner, one or two being for large amounts. A number of these claims had arisen before the date of the balance-sheet, but they had never been presented to the directors. While the audit was proceeding, the directors complained, with a considerable amount of vigour, as to the large amount of the secretary's travelling and other incidental expenses, and the auditors suggested that there should be a general float of £100 upon which the secretary (Mr. Wilson) should draw. This general float was arranged, but the secretary went beyond it and overdrew to the extent of £500. Further than that, certain account books were ordered by his colleague, Mr. Ravenscroft, and himself, to be kept and periodically produced by the secretary, but that official would not carry out their instructions. Both he (the chairman) and Mr. Ravenscroft resigned their positions because they could not get their orders obeyed. Colonel Wilson also complained of the secretary's inattention to his duties, and dismissed that official. The secretary was permitted to take risks up to a certain amount. If there were any of an extraordinary character he had to communicate with certain of the directors and get their sanction. The risks selected by the secretary did not justify confidence in him at all. On one occasion Mr. Wilson waited upon him at his private residence as to a special risk, and he (the chairman) said he would only take it if Mr. Sydney Lee, another director, should agree; instead of going to Mr. Lee, the secretary went to Mr. Carmichael, and the risk was taken. In view of the advertising which was done, a large number of applications were expected at the head office, quite apart from the business done by agents. It was true they allowed their clerks, out of office time, to obtain insurers, and a commission was paid them for so doing. In signing the policies, it came to the knowledge of the directors that there were very few head office applications, a bookkeeper in the office, named Ponsford, being apparently a very large introducer of business. After the secretary was dismissed, they found there were a large number of cheques, signed by directors, for the payment of claims, which had been left about and never presented, and that the claims-clerk had been carrying about in his pocket cheques which ought to have been given to insurers. This state of things set them inquiring; so they took 20 policies at random and wrote to the insurers, whereupon they ascertained that in every case, although Mr. Ponsford claimed commission, they had applied direct to the Company by letter. Mr. Ponsford, by the way, was brother-in-law to the secretary, and it was the duty of the latter to open letters. There was commission also being taken to the extraordinary extent of 40 per cent. in the name of Copping, a person whom the directors believed to have no real existence, unless he was another brother-in-law of the secretary. In view of such proceedings, how could the business be expected to go on satisfactorily and show profits? The directors claimed that they had not been remiss in the discharging of their duties. It was with infinite satisfaction that they announced that that day they were instituting proceedings against Mr. Ponsford, which they hoped would clear things up. The cycle business to September, 1897, showed an income of £791, but, of course, in the first year a great deal of time was spent in getting the agents together. Since September, up to May last, the income had amounted to £720, and on the authority of Mr. Jeffries, their present able manager and secretary, he was able to say they anticipated an income for the current year of £3,000. Their claims were comparatively insignificant, and they had proved that the business for which the Company was originally established was a paying one, and with proper management could be made to pay handsomely. Since the dismissal of the late secretary they had had hundreds of applications coming in by post to the head office; and they had lately had an offer—which was still open—of 1,100 policies in one batch. These they hoped to arrange for, and if the business were accepted this would form a groundwork for future operations. They would now, moreover, be able to make a considerable reduction in their working expenses. If the shareholders would come forward and provide the Company with money—rateably in proportion to their holdings, or in any other way—the Board would be able to render a very good account of it, and be able to show that the business was a very profitable one. He would move: "That the directors be empowered to issue £5,000 6 per cent. shares, preferential both as to capital and dividend."

In reply to Mr. Parry, the Chairman said the original nominal capital was £25,000. They went to allotment on a subscription of £12,000. The Board had no reason to think the secretary was acting as he was, and without sufficient reason it would have been impossible to dismiss him. He did not suggest that the secretary used the £500 overdrawn other than for the purposes of the Company, but he did say that official was very extravagant.

Mr. Wilson, the late secretary, then addressed the meeting. He thought investigation was necessary, and would therefore move the appointment of a committee to inquire into the directors' management of the business. He denied that he was discharged from office, stating that he resigned. He then proceeded to ask several questions as to whether certain of the directors derived any profit from the promotion of the Company, whether they were in arrear with their calls, and whether interest had been paid on overdue calls. He declared that Sir Edward Lee sat on the Board for 16 months without qualifying, and that he did not pay for his qualification until he had received his fee cheque. He (the secretary) had worked up a solid business for the Company, and was prepared to justify his position before any Court of Justice in the world. As to the £500, although the directors passed these overdrafts and drew cheques in his favour, there was never sufficient money in the bank for those cheques to pass through. He was compelled to overdraw his account, and every penny was spent legitimately.

The Chairman, in reply, said he had close business relations with one of the promoters of the Company, and might have made some profit indirectly out of the promotion; but he would point out that he and Colonel Wilson subscribed for 3,000 shares to make up the required capital, and they did this on the distinct understanding that they should only pay the money as and when required. He, personally, had paid every shilling due on his shares. It was not likely that they would pay interest on the balance which remained; they could hardly be expected to take a risk and pay interest too.

After further discussion of various details which the shareholders present felt were really matters for a committee, Messrs. Stenning, Liddell, and Davis were, with the concurrence of the directors, appointed a committee, with power to add thereto, to inquire into the affairs of the Company, and the resolution passed further provided that the meeting should stand adjourned until a balance-sheet was forthcoming.

The meeting accordingly stood adjourned.

Electrical Power Storage Company.

The ninth ordinary general meeting of the shareholders of this Company was held on the 14th ult. at the offices, 4, Great Winchester Street, Mr. John Irving Courtenay presiding.

The Chairman, during his speech, said: The balance-sheet which has been sent to you shows, after payment of debenture interest, a net profit for the year of £4,389 6*s.* 5*d.*, which, together with the sum of £242 0*s.* 2*d.* carried forward from last year, makes a total of £4,631 6*s.* 7*d.*, out of which the directors recommend a similar dividend to that of last year, viz., 5 per cent., carrying forward £356 10*s.* 7*d.* During the year buildings have been erected on part of the new premises mentioned at our last meeting, at a cost of £2,028 8*s.* 9*d.* New plant has been provided for this and other portions of the works, at a total expense of £1,910 0*s.* 11*d.*, and we have maintained existing buildings, plant, and tools at a cost of £2,610 12*s.* 1*d.*, so as to keep the whole of these in thoroughly good order. Notwithstanding the severe competition which now exists, I am pleased to tell you that there has been a very considerable

2 N

increase in the amount of business transacted over that of any previous year, and the increased space at our works has enabled us to cope with the demand. Since our last meeting we have received the Royal Warrant of appointment as storage battery makers to Her Majesty the Queen. As you are doubtless aware, the obtaining of these warrants is a matter of considerable difficulty, and the Electric Power Storage Company is the first and only firm to which a Royal Warrant has been granted for any electric appliance. The chief development in traction during the past year has been the starting of a service of cabs by the London Electrical Cab Company, which cabs ply for hire in the streets and carry passengers at the usual fares of horse vehicles. The whole of these are equipped with our Faure-King cells, and each cab carries a battery capable of taking it a distance of 50 miles without re-charging. We have been unable to find any other storage battery at present manufactured commercially in this country or abroad from which a run of more than 30 miles can be obtained from the same weight and dimensions of battery as ours. The service, which was started in August of last year, has been continued successfully ever since, and we have at present in hand for this Company large orders for extensions. The Compagnie Générale des Voitures in Paris and its allied Company have ordered several sets of these Faure-King batteries for their electrical cabs, and they are at present running some four or five experimental vehicles with them, and with great success. With regard to improvements in secondary batteries and patents therefor, it has been the aim of the directors to ensure that this Company shall always retain its premier position in the storage battery industry, and with this object every invention which is brought to its notice is fully investigated, and where samples can be made or obtained, they are carefully tested in the Company's laboratory, and no trouble or expense is spared in order to thoroughly investigate the merits of each particular case. Whenever there is reason to believe that the Company's manufactures would be improved by the adoption and use of an invention, it is our policy, wherever possible, to make such arrangements as to ensure the Company obtaining the sole right for its use. It is a matter of considerable satisfaction to your directors that, notwithstanding the increase in price of raw materials, especially of our staple article of consumption, lead, they are able to recommend the same dividend as paid for the last six years, and for this they are indebted to the steadily increased output of the works and constant attention of the staff to economy in production. I now move the following resolution:—"That the directors' report and balance sheet to May 31st, 1898, be and are hereby approved and adopted, and that a dividend of 5 per cent. on the paid-up capital be declared payable forthwith."

Sir James Pender seconded the resolution, which was adopted unanimously.

New Electricity Supply Syndicate.

The statutory general meeting of the New Electricity Supply Syndicate (Limited) was held on July 25th, under the presidency of Lord Lurgan (the chairman of the Company), who during his speech said:—This Syndicate was formed for the purpose of acquiring Mr. Rowbotham's patents in connection with his primary generator or battery. We are all aware that so far primary batteries have been tried by the thousand, and thousands of pounds have been spent in vainly trying to produce one which will supply electric light or power at a commercial price. I am glad to be able to tell you that by Mr. Rowbotham's invention the difficulty has been overcome. Mr. Harrison has practically had one of these generators or batteries under his control and immediate supervision for several months past, and if you study his report you will find it is quite as satisfactory as that of Professor Thompson, if not more so. Professor Thompson's original report on this generator, which was made months ago, contained some preliminary observations, in which he says, referring to primary cells or batteries:—"I have found no cell that would give one Board of Trade unit at a lower cost than 1s. 3d. per unit." He concluded that report by bringing down his figures to 6¾d. a unit, which he certified to be the cost. I asked him the other day why he did not give the original people a report sooner? He said:—"I could hardly believe the results of my own tests, and I was anxious to be perfectly certain before I issued a report on the subject." Subsequently he brought the price down to 6¼d. per unit, but we have every reason for stating that we shall get it considerably below that when certain improvements and alterations as suggested and designed by Mr. Rowbotham and also by Mr. Harrison have been perfected. If you refer to Mr. Harrison's report you will notice he says:—"If we add this to the cost of 3·25 lbs. of iron, we obtain a total cost of under 5d. per Board of Trade unit." The advantages of this generator are so numerous that I should weary you if I went into details. I will content myself by drawing your attention to some of the most important points and facts connected with it. In the first place the cost of the installation of this generator is less than half that of the present system of installing accumulators, dynamos, and engines. We require less than half the space occupied by engines, dynamos, and accumulators. The action is automatic, and neither engineers nor skilled labour of any sort is required to supervise this battery and keep it in working order. We shall possess the only generator that can efficiently generate electrical energy without the use of moving machinery. The active materials of our generator are cheap, and can be obtained in unlimited quantities. No doubt you will realise the numberless purposes to which this generator can be applied, and the demand that is bound to ensue for it. As I said before, the poorest as well as the richest will be able to have electric light, for the smallest as well as the largest houses can be supplied with these generators; they will work equally well on a small as on a large scale. Then they are applicable to the lighting of ships, and for electric launches, in which latter respect our battery will do away with the necessity of supplying or charging stations. By a very slight alteration in the construction of this generator it will apply to the propelling of all carriages by electricity. It will come in use for electric trams just as well, and do away with the enormous expense of laying the lines with copper as at present. Altogether, I think you will agree with me that the future of this Company is beyond calculation.

The proceedings then terminated.

The Daimler Motor Company (Limited).

An extraordinary general meeting of the above Company was held in the Throne Room, Holborn Restaurant, on Monday, the 8th inst., for the purpose of considering and, if thought fit, passing a resolution for the appointment of a Committee of Investigation in relation to the statements made by Mr. Sturmey in two circulars bearing his name and dated July 21st, 1898, and all such other powers as to the meeting may seem necessary. A fair sprinkling of shareholders attended, and Mr. J. H. Mace (chairman *pro tem.*) presided over the meeting. The objects of the meeting were fully discussed by various shareholders, and from the statements made by several of the directors, including Mr. Sturmey, Mr. Holt, and the Chairman (Mr. Mace), it appeared that the entire bother was more of a personal disagreement among the directors than anything actually wrong in the affairs of the Company itself. After a great deal of discussion as to the appointment or non-appointment of a Committee of Investigation, it was decided not to go into any of the details of the disagreement at the public meeting but to appoint a Committee of three.

The following resolution was then passed:—"That a shareholders' Committee of three members be appointed to investigate the statements made by Mr. Sturmey in his two circulars, such Committee to be endowed with full powers to employ any professional assistance they may require, and to have access to all the books and records, and to call the assistance of the Company's officials and servants; to report fully to the shareholders as to the past management of the Company, and to make such suggestions as they may think necessary for the conduct of the Company's business in the future, such proper expenses as the Committee may incur to be defrayed by the Company."

Under this resolution Messrs. Rawlinson, Avery, and Leake were appointed to act as a Committee, and the meeting then terminated.

The London General Omnibus Company.

The London General Omnibus Company have issued their report for the last half-year's working. The gross receipts for the half-year were £553,223, against £539,438 in the corresponding half of 1897. The increase of £13,785 in the receipts is more than counterbalanced by the increase of £32,473 in working expenses, making the net profit £18,679 less. The chief part of the increase in expenditure is due to higher prices for provender and bedding for the horses, the average cost for each stud having been £128, as against £123 in the corresponding halves of the two preceding years. The average number of omnibuses running was 1,190, against 1,100 last year, and the average receipts for passengers per omnibus per day were £2 10s 1¾d., against £2 12s. 11½d. The total number of passengers carried in the half-year was 89,569,124, against 83,277,814 last year. The total expenses on revenue account in the half-year were £512,194, and in the corresponding period of 1897 they amounted to £479,720. The expenditure on land, stables, and buildings in the half-year amounted to £55,436. The total number of horses owned by the Company on June 30th last was 14,991; on June 30th, 1897, it was 13,740. The omnibus stock has been well maintained, and 67 new omnibuses were built at the Company's coach factory in the half-year and placed on the road. The profit and loss account is as follows:—Amount brought from last account, £15,053; profit on working for half-year ended June 30th last, £41,029; interest and dividends on investments, £4,950; premiums received on 4 per cent. mortgage debentures, £4,458; unclaimed dividends for 1892 forfeited, £147; total, £65,638. Interest on debentures to June 30th, £3,038; carried to general reserve fund, £10,000; dividend for the half-year after the rate of 8 per cent. per annum and bonus of £1 5s. per cent. (equal to 10¼ per cent. per annum), free of income tax, £38,290; leaving balance to be carried forward to next account, £14,309.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

Automobile Association (Limited).—Registered by Cutler and Co., 15, Duke Street, St. James's, S.W. Capital £10,000, in £1 shares. Object, to carry on the business of dealers and proprietors of motor and other carriages, vans, wagons, cycles, and other vehicles, jobmasters, carriers, motor-car builders, carpenters, joiners, engineers, machinists, rubber manufacturers, &c. Offices, 1, Princes Road, Holland Park Avenue, W.

Bell Hall Tyre Syndicate (Limited).—Registered by Hudson and Kearns, 83, Southwark Street. Capital £50,000, in £1 shares. Object, to adopt an agreement; to acquire the letters patent No. 27,225 of 1896, granted to Robert Bell and W. T. Hall, in respect of an invention for improvements relating to pneumatic tyres for cycles and other vehicles; and generally to carry on business as manufacturers of and dealers in cycles, motor-cars, fittings and accessories for the same, &c.

Crewdson, Hardy, and Co.—Capital £55,000, in £5 shares. Object, to acquire and take over as a going concern the business carried on at Middlesborough, Yorks., under the style or firm of Crewdson, Hardy, and Co., and to carry on the business of tube manufacturers, fitting and mechanical and general engineers, cycle and motor-car manufacturers, &c. The first directors are: Sir Raylton Dixon, J.P., John Livingston, and William H. Hardy.

Patent Wheel and Axle Company.—Capital £25,000, in £1 shares. Object, to adopt an agreement with Scott's Patent Wheel and Axle Syndicate (Limited), and to carry on the business of patent wheel and axle manufacturers, motor-car builders, &c. Registered office, 50, George Street, Newport (Mon.).

Pneumatic Direct Propulsion Syndicate (Limited).—Registered by Van Sandau and Co., 13, King Street, E.C. Capital £5,000, in £5 shares. Object, to adopt a certain agreement, and to acquire, work, and develop certain patents and other rights for a system of pneumatic propulsion, belonging to Mr. L. Hopcraft.

Railway Developments (Limited).—Registered by Leggatt and Co., 5, Raymond Buildings, W.C. Capital £100,000, in £1 shares. Object, to carry on the business of railway and tramway proprietors and carriers, to construct and supply motor-carriages, locomotives, or other vehicles, &c.

THE Vallée Motorette, which took part in the recent motor race from Lille to Calais, is likely to be seen shortly in England in goodly numbers, as a Company has been formed, entitled the Vallée Motorette Company, 131, Gloucester Road, Regent's Park, N.W., for the purpose of introducing it to England on an extensive scale.

Liverpool Trials of Moto-Vehicles for Heavy Traffic.

MAY 24TH TO 27th, 1898.

THE following are the unanimous awards of the Judges:—

Official No. 5.—First prize, £100. The Lancashire Steam Motor Company, Leyland.

Official No. 1.—Second prize, £75. The Liquid Fuel Engineering Company, East Cowes, I.W.

Official No. 4.—Third prize, £50. The Steam Carriage and Wagon Company (Ltd.), Chiswick.

DAVID L. SALOMONS.
BOVERTON REDWOOD.
S. B. COTTRELL.
H. S. HELE-SHAW.
HENRY H. WEST.
E. SHRAPNELL SMITH,
Hon. Organising Secretary.

The full report will be issued later in the year.

Those Terrible Moto-Vehicles!—At a meeting of the Leamington Town Council on the 8th inst., Councillor Molesworth referred to the lack of regulation of traffic in Leamington, and said he had been obliged to bring the matter before the Watch Committee. If the traffic was not better regulated there must soon be a serious accident. Alderman Wackrill said any moto-car could be stopped by a person holding up his hand. Alderman Thursfield (deputy mayor) said moto-car drivers ignored requests to stop. He was nearly run over the other day by a moto-car. His horse went dancing all over the place, and when he requested the people in the car to stop they refused and laughed at him. Several members of the Council expressed the opinion that more stringent regulation of the street traffic in Leamington was desirable, and even necessary, and the Mayor said the Chairman of the Watch Committee would see the Chief Constable on the matter.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to The Editor of "The Automotor and Horseless Vehicle Journal," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. King and Co., Limited, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. King and Co., Limited, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

The Automotor and Horseless Vehicle Journal *can be obtained from all* Messrs. W. H. Smith and Son's *bookstalls, and the following Agents :—*

London: Wholesale—Brett and Co., 5, Pilgrim Street, Ludgate Hill, E.C.; Munton and Co., 7, Red Lion Court, Fleet Street, E.C.

Birmingham: J. McCann, 37, Union Street.

Manchester: John Heywood, Deansgate.

Newcastle-on-Tyne: C. C. Ross, 35, Side.

Paris: Homère Moreau, 97, Rue Nollet.

Victoria (Australia): Phillips, Ormonde, and Co., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

Proprietors and Publishers— F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

„	Motor-Car Exhibition at Tunbridge Wells.
„	Heavy Motor-Vehicle Competition at Liverpool.
„ October..	Concour des Poids Lourds at Versailles.
1900	Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

J. T.—Yes. The "Joy" valve gear is well known to us, and you can apply it with confidence to your steam vehicle. Let us know how it works.

S. Smith.—The Lundell motor has two separate magnet poles and one winding.

Petrol.—"Tea Rose" oil, as sold by the Anglo-American Company, has a flash point of 82° F. (Abel close test), and a boiling point of 304° F. Its specific gravity is ·797.

Oil Motors.—Yes. New and Mayne, of Woking. Roots and Venables, of London, make oil motors, using ordinary burning oil of 73° flash point. These are eminently well suited for vehicles.

Student.—In the New York trials of electric cabs 1 effective H.P. was obtained from 300 lbs. of battery, and 1 H.P. from 100 lbs. of battery.

E. S. (Bromley).—(*a*) We shall republish the Petrol List from time to time with additions, and it will also be published in very complete form in our next Pocket-Book. (*b*) We shall be always glad to know of any adulteration as mentioned by you, so that we may record such firms on a black list.

B. L. (Herne Hill).—(*a*) We hardly think so. (*b*) Apply to the Southern Motor-Car and Cycle Company, 59, Brixton Road, London. They can carry out what you want and they also supply Benz vehicles on much improved principles. See our July number, p. 399.

T. R. D. E. (Kelso).—Regret impossible to supply you with No. 1, Vol. I, separately; should be very glad to have some ourselves. We have still two or three bound in volume form complete at one guinea.

Petrol (South Shields).—You can obtain a Benz motor-vehicle from Friswell's, 18, Holborn Viaduct, London, or a "Richard," which is an improved Benz, of the Southern Motor-Car Company, 59, Brixton Road.

Guardsman at Play.—A battery of storage cells is quite free from any risk of explosion so long as they are placed in well-ventilated situations. If, however, confined within boxes, the nitrous oxide fumes are liable to accumulate, and these form with air an explosive mixture which might be exploded by contact with a naked light.

THE THREE-TON LIMIT.

The unanimous resolution of the Liverpool Centre of the Self-Propelled Traffic Association at their last meeting to exert the whole force of the Association in order to obtain an amendment of the Locomotives on Highways Act in the direction of removing all restrictions upon the weight of vehicles will, we think, be generally approved of, and supported by all those who see, as we do, in automobilism on common roads, the solution of those economical problems that at present beset the farmer, the railway carrier, and the legislator. We do not intend to discuss the reason why eggs, flowers, and butter produced in France are carried over our railways at a fraction of the cost that is charged for the same commodities produced but a few miles from our own doors. We may revise rates, and talk glibly enough about our 5-ton and 10-ton consignments and the rebate on them, and we may bewail that the British farmer is hopelessly conservative. All this does not alter the fact we have stated. During its existence the S.P.T.A., or rather the Liverpool Centre, has by means of discussions, papers, and practical trials demonstrated the possibilities of the 3-ton limit, and has concluded that it is desirable to remove all restrictions upon weight. On the other hand, many automobilists think that the possibilities of the 3-ton limit are not yet exhausted. Thus Mr. F. Simms, in a letter to us, deprecates any alteration in the Act at present, and we have reason to know that his views are shared by a good many other gentlemen. For ourselves, while believing it is possible to produce a vehicle weighing not more than 3 tons that shall carry at least two and a half times this, we strongly advocate raising the limit to at least 4 tons, because this permits heavier scantlings and a larger factor of safety in the boiler, and generally greater endurance; it also means less damage to roads. Of course, this remark applies more strongly if all restrictions on weight are removed, but in the latter case the result would be the construction of vehicles that would be like miniature tramp steamers on wheels, and we should find a somewhat analogous state of affairs obtaining on land as prevailed at sea some years ago—low engine powers associated with great weight of load carried. At the same time, the view of the S.P.T.A. is a perfectly logical one, and we do not see how it can be seriously contested. They, in fact, point out a serious anomaly under which motor-vehicles labour as compared with horse-drawn vehicles. This will be seen by taking a few instances.

Suppose a mass of machinery some 10 to 12 tons has to be moved. A trolly weighing certainly over 3 tons and drawn by 10 or 12 horses would be employed, the weight of the vehicle unladen and its hauling power being not less than

8 tons. A light motor-vehicle could not be employed because the weight of such is limited to 3 tons unladen, and it would not at present be possible to get the power and strength of structure into vehicles on this limit. Why should it in effect be unlawful to build or employ a self-propelled vehicle for this purpose? Taking a more usual and more moderate load we see the same anomaly; the horse-drawn vehicle can be of any weight and drawn by any number of horses; the motor-vehicle must still be strictly limited to 3 tons. Moreover, too, it has to be licensed, and is taxed. Why should this be? Why should a heavy railway goods van weighing unladen 2 tons, or with its three horses 4·6 tons, be a legal means of transport and be free from taxation, and motor-vehicles not only be taxed but, if over 3 tons, be an absolutely illegal means of transport?

Let us retain the 3-ton limit by all means, but let us be logical. Let us say that *no* vehicle with its motive power shall weigh more than this, and that *all* vehicles shall be licensed and taxed; or, better still, let us say that ALL vehicles weighing, with their motive power, over 4 tons, shall be specially licensed and shall be taxed. We would, however, urge upon all parties, no matter what be their views, the desirability of approaching this subject in a judicial spirit of pure logic.

Those who, thanks to their position and influence with the Government, assisted in getting us the Locomotives on Highways Act, against some very cordial and truly British opposition in both Houses, naturally regard that measure, even incomplete and illogical as it is, with feelings of affection, and would like to see its possibilities tried further yet before considering amendment. The fact is, however, that the progress of heavy automobilism in France, and the great scope for it in this country, have so forced themselves upon the attention of commercial men, that an early amendment of the Act in the direction of at least an increase in the tare weight of a vehicle unladen, leaving for the moment other considerations, is imperative.

SIR DAVID SALOMONS ON AUTOMOBILISM.

WE publish in our present issue a translation of a most interesting letter that Sir David Salomons, the President of the S.P.T.A., has addressed to M. Paul Giffard, the editor-in-chief of our well written and excellent contemporary *Le Velo*. Sir David makes a most effective comparison between our and Continental methods in dealing with automobilism. In England we complain of too much law—too much restriction. In France one finds nearly every transaction in life minutely regulated by law. We are seeking to place motor-vehicles on the same legal footing as horse-drawn ones, and with every prospect of success; in other words we are seeking to remove restrictions. In France an elaborate bureaucratic system is being built up which Englishmen would not tolerate for a moment. Fancy having to produce one's birth certificate before being licensed to drive a motor-vehicle! We do this thing, at any rate, much better on this side of the channel. Thanks to our law-abiding instincts, automobilism in England is a gradually growing social and economic influence of the most far-reaching possibilities. In France it is mostly a pastime for the leisured classes. In England the law relating to automobiles can be written on one page of this journal. Anyone who has the means can own a motor-vehicle. Anyone who likes to take the task can drive one. Our law does not say a word about the qualifications of either owner or driver, but it says a lot about the rights of those who are run over. In France the law says the owner and driver must comply with a long series of regulations; it takes little thought of those who may be injured by reckless driving. Hence, automobilism in France is likely to be a public nuisance; in England it will be as great a benefit as railways, and the reason is to be found in the difference in the characteristics of the Latin and Anglo-Saxon races. It is this self-reliance, this respect for wise laws, that has made this country what it is.

There is an increasing party among us which seeks to imitate the French method, and would regulate all affairs of life by law. One constantly hears these feeble-minded folk say "there ought to be a law" for this, that, and the other.

We entirely share the view of Sir David Salomons on this matter of the law of automobilism. A number of regulations such as they have in France would effect no practical good, but would retard the progress of the industry. We may safely rely upon the natural good sense and law-abiding instincts of the majority of English automobilists to render the imposition of any further legal restrictions quite unnecessary.

We would recommend a perusal of Sir David Salomons's letter to our provincial magistrates, horsy J.P.'s, and to those amœbic folks one finds on county councils, and on similar bodies, who are always seeking to impose a new law upon their neighbours, and who see salvation in an Act of Parliament.

We observe with pleasure that Sir David Salomons is an individualist. In these days of frothy declamation a few utterances, such as the letter we have referred to, do much good.

LIVERPOOL TRIALS OF MOTO-VEHICLES FOR HEAVY TRAFFIC.

MAY 24TH TO 27TH, 1898.

THE following are the unanimous awards of the judges:—

First prize, £100	..	The Lancashire Steam Motor Company, Leyland (Official No. 5).
Second prize, £75	..	The Liquid Fuel Engineering Company, East Cowes, I.W. (Official No. 1).
Third prize, £50	..	The Steam Carriage and Wagon Company (Limited), Chiswick (Official No. 4).

As we shall publish the judges' report in our next issue, we need only remark on the above that their finding is, we think, a proper one, and as such it will be generally accepted. Those who might be inclined to entertain different views as to the relative merits of the vehicles must remember that the judges had full particulars and data of each vehicle, which others had not, and in arriving at any opinion many factors other than those apparent at trials have to be considered. In describing the trials we gave a preliminary analysis of the performances* of the vehicles, and from this it will be seen that our inferred conclusions have been generally supported by the above finding. Another remark that we may permit ourselves to make is that the first and second prizes have been gained by vehicles using petroleum as fuel, notwithstanding the extra cost of the latter as compared with coal or coke. It must, however, be remembered that ease of manipulation, freedom from dirt, sparks, &c., are important considerations which, if all conditions are known, can be expressed as having certain money values, and these no doubt influenced the committee a good deal. The exclusion of the official No. 3 from the awards is, we think, clearly due to mechanical features of that vehicle, such as the low evaporative power of the boiler and the adoption of an articulated joint, together with a want of sufficient adhesion on the drivers.

AUTOMOBILISM AND SOCIALISM.

MUNICIPAL bodies are very extensive users of horse-drawn vehicles for various purposes, and once the superiority of the motor-vehicle from the mechanical, sanitary, and economical points of view is demonstrated we may be sure that a very large business will be done in the construction of such vehicles. Already Chiswick and Liverpool have set an example that may well be imitated, and to our knowledge several firms are acquiring premises, laying down plant, &c., for the purpose of building municipal motor-vehicles. It, therefore, becomes a question of some moment to consider the terms upon which municipal bodies enter into contracts with manufacturers. In general these contracts are of a purely business nature, but of late years it has been customary to insert clauses which ensure the payment of the standard rate of wages to the workmen, the prevention of sweating, &c. This is as it should be; large and wealthy customers, as municipal bodies are, can properly set an example in these matters and create a healthy public opinion in the matter of the treatment of workers. The London County Council—the largest municipal body in the world—however, adopts a proletarian attitude

* *Vide* THE AUTOMOTOR for June, p. 333.

and insists upon terms in its contracts which seem to go far beyond what is justifiable either from a legal, moral, or business point of view. It seeks, in effect, to carry out principles of advanced Socialism—not that we say such principles are wrong in themselves, but they are certainly not yet practicable in our present very cosmical society. A very remarkable instance of this has lately been furnished by the publication of some correspondence that has passed between the London County Council and the very eminent firm of nautical automobilists, Messrs. Yarrow and Co., of Poplar. Readers of THE AUTOMOTOR will know that we have taken considerable interest in the question of motor fire-engines and have repeatedly pointed out the inefficiency of the Fire Brigade plant both afloat and on land. Our remarks have not been without effect, but of this we speak elsewhere. In THE AUTOMOTOR for April of this year we gave particulars of a new fire-float that Messrs. Yarrow had designed for the London County Council and which the Fire Brigade Committee had recommended the Council to adopt. This the Council did and sent on its contract for Messrs. Yarrow to sign.

Messrs. Yarrow naturally expected that this document would be an ordinary shipbuilding contract, such as they were accustomed to. They received a volume of some 17 or 20 pages, containing, *inter alia*, the following clauses, which we especially commend to the notice of those of our readers who are manufacturers:—

Clause 16.—"The foreman shall not be changed without the consent of the chief officer, but may be objected to or dismissed by the chief officer if and when he shall see fit, and thereupon the contractors shall cease to employ such foreman or foremen, and employ another or other good and competent foreman or foremen in his or their stead, and so on from time to time so often as occasion shall require."

It further on says:—"The chief officer shall be at full liberty to object to or dismiss any person employed by the contractors who shall, in the opinion of the chief officer, misconduct himself," &c.

Clause 34: *Para.* 1.—"The contractor shall pay all workmen—except a reasonable number of their legally-bound apprentices—employed by them in and about the execution of this contract, or any part thereof, wages, and wages for overtime respectively, at rates not less than the rates stated in the second schedule hereto; and for each and every breach by the contractors of this stipulation, and notwithstanding the condonation of any prior or other breach, the contractors shall, on demand, pay to the Council as liquidated damages, and not as a penalty, the sum of £5.

Para. 2.—"The contractors shall observe and cause to be observed by all such workmen, hours of labour not greater than the hours of labour stated in the said second schedule, and for each and every breach by the contractors of this stipulation, and notwithstanding the condonation of any prior or other breach, the contractors shall on demand pay to the Council as liquidated damages, and not as a penalty for each day on which any such breach shall be committed, and for each workman in respect to whom it shall be committed, the sum of 5*s.* per hour for every hour during which on each day each workman shall be employed by the contractors beyond the maximum number of hours stated in the said second schedule, provided that this stipulation shall not be construed to prohibit overtime, if such overtime be in accordance with the rules of the trades unions concerned."

Para. 3.—"The contractors shall at all times during the continuance of this contract display and keep displayed upon the site of the works, and in every factory, workshop, or place occupied or used by the contractors in or about the execution of this contract, in a position in which the same may be easily read by all workmen employed by the contractors in or about the execution of this contract, a clearly printed or written copy of the said second schedule hereto."

Naturally Messrs. Yarrow hesitated to accept such onerous clauses, and finally declined the business. They pointed out that the insertion of such clauses by the Council "will undoubtedly be that the firms executing the highest class work will be prevented from accepting such contracts, and that the cost of the work will by natural processes be greatly increased, not only to the detriment of the Council itself, but also to the injury of those public interests that it is intended to preserve; while the harmonious relations existing between employers and their employés, which it should be the desire and effort of all public bodies to maintain, would be seriously jeopardised."

The Council reply to the effect that after consideration they could not vary the contract, and "as the matter is urgent must reluctantly seek tenders from other firms." A debate on the matter ensued subsequently, and notwithstanding that many members pointed out the grave consequences that would ensue if the policy as exemplified in this precious contract were adhered to it was decided to proceed no further in the matter. In the meantime we trust, for the reputation of the Council, that a more common-sense view of what is essentially a business and not a philanthropic transaction will obtain.

Our view of the matter is this. As the prospective purchaser, the Council has the undoubted right to insert any clauses in its contracts, no matter of what kind, so long as these are not in themselves immoral, illegal, or opposed to public policy. The determination of the propriety or legality of any contract rests with third parties, viz., the judges. Opinions may well differ as to the propriety, legality, or even morality of the clauses in the contract referred to. Their legality is, at any rate—we have authority for saying—very doubtful. Be this as it may, the effect of such clauses is to enhance the ordinary contractor's risk. Supposing the official of the County Council insisted upon the dismissal of a foreman, who was a member of the A.S.E. or I.S. and B.M. unions, the works would be at once "struck." The dismissed workman could possibly even maintain an action for damages. Unless, too, the contractor in his other contracts had protected himself by the "Strike clause," he would be liable to other parties, he might even become bankrupt. That, however, is a detail; our point is that the insertion of these clauses by the County Council merely creates an additional risk, which, like all other risks, may be underwritten. In the present case the risk of a partial or total stoppage was very real, and by no means a remote contingency, and before the firm in question could have accepted the business from the County Council, their quotation for it would have to be increased by at least some five per cent. In short, the insertion of these clauses means that the public pays the premium of the inevitable and necessary underwriting. Even when a contractor is thus insured he is not fully compensated for the loss of time, worry, and trouble he incurs, and so it comes about that the better class of firms do not care to tender for County Council work. This fact is rather ruefully admitted by the County Council semi-official organ, *London*, which in a recent issue says:—"The contractors are not very keen to obtain work under the County Council just now. Only two tenders, it may be remembered, were obtained for the Greenwich Tunnel—a passenger tunnel on the same lines as the Blackwall Tunnel, and the tenders were much in excess of the engineer's estimate."

Naturally; the risk of loss is so great that, as a matter of prudence alone, it is necessary to charge more in order to cover the premium of insurance. The question for the ratepayer is, Is it necessary to pay this higher price, or, in other words, is it worth while to retain these clauses in the London County Council contracts?

It will be noticed that we regard the matter as a purely business one, and express no opinion on the political influences at work on the Council, but which bid fair to make it a "machine," compared to which Tammany Hall, of New York, is a seat of enlightened municipal government.

Personal.—Mr. W. Worby Beaumont left England on a visit to the United States on the 12th inst., to inspect and report on a special class of machinery, electrical working of machine tools, and on certain manufactures. Motor tramcar and carriage questions will at the same time occupy his attention. He will return at the end of September.

The Liverpool Corporation and Automobilism.—Under this heading we published in our July number a paragraph referring to the placing of an order by the Liverpool Corporation for a steam motor-vehicle for municipal purposes. Our remarks on this were, we admit, of a slightly sub-acid nature, but written in good faith and without malice. Unfortunately, they have given some offence to some gentlemen concerned, who see in them some reflection imputing a want of enterprise on their part in not placing such an order earlier. We hasten to take this first opportunity of expressing our regret that our remarks should have occasioned this most undesirable result. We willingly state that, so far from intending or wishing to reflect in any way upon any gentleman connected with the Corporation, we recognise that in placing this order so soon after the late trials the Corporation was well advised, and showed a most public-spirited enterprise in acting upon that advice. We trust that this explanation will be accepted in the spirit it is made, and that an incident that we deplore will now be regarded as closed.

THE AUTOMOBILE CLUB OF GREAT BRITAIN AND IRELAND,

With which is incorporated the Self-Propelled Traffic Association.

AN extraordinary general meeting of members of the above-named Club was held on Tuesday, August 9th, at 1 p.m., at the premises of the Club, 4, Whitehall Court, London, S.W.

Among those present were:—Mr. Roger W. Wallace, Q.C., Chairman of the Club (in the chair), Mr. Frederick R. Simms (Vice-Chairman), Mr. Frank H. Butler (Hon. Treasurer), Mr. C. Harrington Moore (Hon. Secretary), the Right Hon. the Earl of Galloway, K.T., Sir Douglas Galton, Bart., K.C.B., F.R.S., Sir David Salomons, Bart., J.P., Messrs. W. Worby Beaumont, Herbert Capel, Thos. Clarkson, C. Cordingley, T. W. Staplee Firth, A. S. Gilbertson, Berger Graham, R. Gray, Julius Harvey, H. Hewetson, J. H. C. Hewett, Chas. Heyermans, E. M. C. Instone, E. Lefébure, H. C. Marshall. J. McManus, P. McManus, H. Melvill, H. J. Mulliner, Arthur Paget, R. Phillips, Bernard B. Redwood, J. D. Roots, Lyons Sampson, O. Scholzig, Alexander Siemens, Stanley Spooner, Alfred Thompson, E. Townsend, Andrew W. Barr (Auditor), and C. Johnson (Secretary).

The Secretary having read the notice convening the meeting, it was moved by the Chairman, seconded by Sir Douglas Galton, and resolved: "That in accordance with the recommendations of the Club Committee the following members be, and they are hereby appointed members of the Club Committee:—Sir David Salomons, Bart., J.P.; Mr. Alexander Siemens; Mr. John I. Thornycroft, F.R.S.; the Hon. C. S. Rolls; Mr. Andrew W. Barr; Mr. Alfred Bird; Professor Vernon C. Boys, F.R.S.; Mr. R. E. B. Crompton; Mr. Walter Hancock; Mr. Bayntun Hippisley, D.L., J.P.. Mr. J. T. Hopwood, D.L., J.P.; Mr. Alfred L. Jones, J.P.; Mr. E. Macrory, Q.C.; Mr. Harry Melvill; Mr. E. Shrapnell Smith; Mr. E. R. Shipton."

Prior to the above-named meeting the following were elected ordinary members of the Club:—Messrs. J. W. Amps, F. P. S. Harris, Bayntun Hippisley, D.L., J.P. (Junior Carlton Club), C. Vernon Pugh (National Liberal Club), Alberto Randegger (Arts Club), John Stirling (Hamilton, N.B.); and among the members of the Self-Propelled Traffic Association who have joined the Automobile Club are:—Sir David Salomons, Bart., J.P. (Whitehall and City of London Clubs and Automobile Club de France), The Hon. C. S. Rolls (Automobile Club de France), Professor C. Vernon Boys, F.R.S. (Savile Club), Dr. John Abercrombie, M.D., F.R.C.P.; John I. Thornycroft, F.R.S.; Messrs. Francis E. Baron (Blackpool), Andrew W. Barr (New Club), H. Percy Boulnois, John Brown (Ulster Reform Club), Fred. J. Burrell, J. G. Carew-Gibson (Junior Constitutional Club), Thos. Clarke, W. A. Darbishire, D.L. (Devonshire Club), Henry T. Davis; Captain H. Murray-Dunlop (late R.A.); Messrs. Walter Hancock, J. T. Hopwood (Carlton Club), Alfred L. Jones. J.P., H. F. Julian (Teignmouth), T. Dove Keighley, Walter N. Landor, B.A., J. P. Lea (Hulme), Washington Lyon (City Liberal Club), Edmund Macrory, Q.C., J. Stewart Mellam (Sports Club), Harry Melvill (Bachelor's Club and Automobile Club de France), E. A. Mitchell, H. A. Naismith, J. A. McNaught (National Liberal Club), F. C. Nunn (Constitutional Club and Royal London Yacht Club), M. R. Pryor (Athenæum and Oxford and Cambridge Clubs), J. Graham Reece (Liverpool), Alexander Siemens, E. Shrapnell Smith, J. E. Thornton (Altrincham), Wilfred Le P. Webb.

ON the 23rd ult. a very enjoyable entertainment took place on the house boat, the "Dolce far Niente," at Shiplake, when Mr. Frank Butler, the Hon. Treasurer of the Club, had invited members owning moto-cars and their friends riding with them as his guests for a day. A magnificent marquee had been erected on the bank, where about 300 had lunch, Signor Bocchi's band discoursing music throughout the day. Among the guests were Mr. Roger Wallace, Q.C., and Mrs. Wallace, Sir John Tyler, C.I.E., Mr. Munton Jaffray, J.P., and his daughters, Mrs. Hiram Maxim, Mr. Herbert do Stern, Mr. and Mrs. Louis D'Egville (who gave a very excellent piano and violin recital on the house boat), Mr. and Mrs. Hodges, Mr. Foster Pedley, Mr. and Mrs. Randegger, Mr. and Mrs. Lyons Sampson, Mr. E. G. Brewster, Mr. Berger Graham, Dr. Leadam, Mr., Mrs., and Miss Mulliner, Mr., Mrs., and Miss W. P. C. Wills, Mr. Instone, Dr. Lehwess, &c., &c. As already announced, two of the Daimler Company's wagonettes and two wagonettes lent by the London Motor-Van and Wagon Company conveyed a number of the members from the Club premises to Shiplake, whilst quite a number of private owners came from various places in their moto-carriages, which included vehicles of the Daimler, Benz, Mors, Le Blon, De Dion, and Bollée types. The weather was fortunately all that could be desired although a little bit windy, and some excellent photos were obtained of the gathering, which have appeared in the *Lady's Pictorial* of the 30th ult. Altogether Mr. Frank Butler may claim the credit of having given one of the most successful functions of the season in connection with the Automobile Club. On the Sunday several of the guests had a run to Oxford and back, *viâ* Streatley, Pangbourne, Tilehurst, Caversham, and Shiplake to the Royal Hotel at Henley, the main body of the company making this excellently-managed hotel their headquarters, whence on Monday the party returned to London by about 11.30 a.m.

DR. C. E. SHELLY, a member of the Automobile Club, has made a suggestion—which has been adopted by the Technical Sub-Committee of the Club—"that if every member owning a motor-vehicle were to contribute to the Club, photographs and reliable particulars of his motor-vehicle or motor-vehicles, these would form a useful album of reference for use by members, and if duplicate copies were presented to and kept by the Club they would constitute an invaluable permanent chronological record of the early stages of the automobile movement." Members are therefore particularly requested to kindly supply to the secretary two copies of a half-plate photograph of their motor-vehicles, printed by a permanent process. The photographs should be taken from a point of view showing the vehicle broadside-on or nearly so, and not more than one adult figure should be introduced into the picture, and this figure should be so placed as not to obscure a view of the vehicle. The information desired, which is very full, is indicated on a proper form supplied by the Club.

Electric Power from Sea Waves.—A company has been making a series of experiments at Los Angeles, in which the force of the waves of the ocean was used to generate electric power for light and other purposes. A wharf made of metal was built, extending 350 feet out into the ocean, and the generating plant was placed at the end. It included three floats connected with vertical hydraulic compressors, which, in turn, were connected with a storage pressure tank. The movement of the waves alternately raises and lowers the floats, pumping fresh water from the reservoir into the storage pressure tank, where the water is subjected to sufficient pressure to drive it out with great force through a water-wheel. This water-motor operates the dynamo, and the water which has passed from the motor flows into the reservoir to be used again. The machinery is almost self-governing, as in case of storm or heavy sea the accumulated pressure in the storage tank exerts itself against the pump pistons and affects the action of the floats. A thorough test of the apparatus was made during the winter, when all kinds of weather were experienced, and the plant is now to be enlarged to a capacity of 200 H.P.

Cork as a Paving Material.—It may not be generally known that cork has been somewhat extensively tested in different parts of the kingdom for some years past as a material suitable for road pavements. Ground up into small particles mixed with bitumen and a suitable fibrous material, when compressed into blocks under a high pressure—600 lbs. per square inch—this material has been found to produce a medium for road pavements which has given excellent results under different conditions. The material is tough, cohesive, and elastic, without being too easily compressed or indented. Not only does it afford a good foothold, but it is practically non-absorbent and noiseless. It is laid in cakes, very much in the same manner as wood blocks, that is, on a cement concrete foundation of a depth suitable to the traffic to be encountered, and the jointing material is bitumen. The Cork Pavement Company (Limited), 21, St. Mary Axe, E.C., have applied a large amount of this pavement, not only in the metropolis, but also in other parts of the kingdom, with, it is claimed, highly satisfactory results. At Liverpool Street Station, London, several roadways have been in use for a number of years paved with cork, and the results are said to have been all that need be desired.

THE LIQUID FUEL ENGINEERING COMPANY'S LATEST TRADE VAN.

The illustration below shows the latest type of the now well-known "Lifu" vans, which has been specially built to the order of Messrs. Spiers and Pond. This vehicle is practically identical in principle with the steam lorry which we announce in our current issue as having been awarded the second prize in the Liverpool Heavy Traffic Trials, and which we fully described in our issue of May 15th last, the only difference being that it is not fitted with sand boxes, and has a covered body as well as accommodation on the roof for parcels. The clear space inside for the accommodation of goods and parcels is 8 feet by 4 feet 8 inches. The vehicle is capable of a speed of 12 miles per hour, and of climbing grades of one in six when fully loaded, the engines working compound. In order to ascend steeper grades, or to propel the vehicle through extremely soft or bad roads, the engines are so arranged that steam may be let into the lower pressure cylinder, which nearly or quite doubles the power.

The engines and boiler are both of 25 H.P., and both the systems of gearing and steering arrangements are identical with those of the Liverpool steam lorry. Band brakes are fitted as usual to the rear wheels and work by means of a foot lever by the driver.

INSTITUTE OF BRITISH CARRIAGE MANUFACTURERS.

The eleventh annual autumnal meeting of this Incorporated Society will be held in Edinburgh, commencing on Tuesday, September 6th, for the reading and discussion of papers, &c. The President for the year is Wm. Angus, Esq., J.P. On the first day a paper will be read on "Application of Motors to Carriages (Private and Public)," by Mr. T. Coward, which is to be followed by a discussion. A special prize competition has also been organised for carriage manufactory employés or the accessory trades, whilst the arrangements for special tours, &c., have been very judiciously provided for. Mr. Barr, accompanied by Mr. John Croall, the honorary local secretary, has arranged on the week previous to the meeting to visit the Trossachs to see that everything is in order, and on the day preceding the meeting will be present in Edinburgh to arrange for the exhibition by the accessory members and the prize competitions.

Owing to the unfortunate illness of Mr. Northey, who was to have delivered a paper on "The Possibilities and Uses of Aluminium in the Construction of Carriages," the programme has been unavoidably altered. The Secretary has stepped into the breach, and will devote a part of his holiday to preparing a paper on "Coachmakers' Accounts." Mr. Barr received a unanimous requisition from the Council to give such a paper, but, owing to his recent election as President of the Society of Accountants and Auditors and the enormous demands upon his time, asked to be excused until next year.

It is unfortunate that Mr. Barr has so little time to devote to the preparing of a paper which, from his knowledge of the coachbuilding industry and his professional experience as an accountant, will be of such infinite advantage, but we trust that it will be the groundwork of his more important publication, "A Treatise on Coachmakers' Accounts," shortly to be issued.

The Edinburgh meeting is exceedingly popular throughout the trade, and the members of the Institute from London, the South and West of England, Ireland, and the extreme North of Scotland have expressed their intention of being present, and quite a number of applications from coachbuilders throughout Scotland to become affiliated with the Institute have been received to enable them to take part in the proceedings.

Notification has been received that the Carriage-Builders' National Association of the United States will be represented, and, although it is not officially announced, we have reason to believe that the members will be received on the second day of the meeting by the Lord Provost of Edinburgh.

LIVERPOOL AND MANCHESTER LIGHT RAILWAY SCHEME.

As we go to press the report is just to hand of the Special Committee on Light Railways, appointed by the Incorporated Chamber of Commerce of Liverpool. The object of the Committee was to inquire into the schemes for the reduction in the cost of transit of merchandise between Liverpool and Manchester and the adjacent districts; the Committee appointed, which includes Mr. E. Shrapnell Smith, the Honorary Secretary of the Self-Propelled Traffic Association, Liverpool Centre, being as follows:—Mr. G. H. Cox (Chairman of Committee); Messrs. F. C. Danson (President of Chamber), Alfred L. Jones, J.P. (Vice-President of Chamber), Charles McArthur, M.P. (Ex-President of Chamber), Sir W. B. Forwood, J.P. (Ex-President of Chamber), Colonel G. H. Morrison, J.P., Messrs. E. W. Bindloss, Danson Cunningham, and *G. F. Ransome, representing the Chamber of Commerce; *Mr. J. T. Wood, M.Inst.C.E., and the Town Clerk (Mr. Harcourt E. Clare), representing the City Council; Mr. Alderman J. Webster, J.P., representing the Bootle Corporation; Messrs. A. G. Lyster, M.Inst.C.E., and J. Barkeley Smith, J.P., representing the Mersey Docks and Harbour Board; Mr. S. B. Cottrell, M.Inst.C.E., representing the Liverpool Engineering Society; Mr. W. D. Heyne, M.Inst.C.E., representing the Cotton Association (Limited); Mr. R. Griffiths, M.Inst.C.E., representing the Corn Trade Association (Limited); Mr. J. Wilson, M.Inst.C.E., representing the Cartowners' Association (Limited); Mr. E. Shrapnell Smith, Hon. Sec. of the Self-Propelled Traffic Association (Incorporated); *Mr. Alfred Holt, M.Inst.C.E.; *Mr. E. R. Calthrop, C.E.; *Colonel A. H. Holme, Assoc.Inst.C.E., J.P.; and Mr. Thomas H. Barker, Secretary of the Chamber.

The steps leading to the appointment of this Special Committee, which has been sitting at the Chamber since February, 1896, practically began with the appointment of the Manchester Shipping Canal Special Committee, on January 15th, 1894. After the most exhaustive inquiries the following are the recommendations unanimously arrived at by the Committee:—

The Committee are unanimously of opinion that Colonel Holme's scheme for a goods railway between Liverpool and Manchester contains greater promise as a thoroughly economical and otherwise satisfactory means of conveying merchandise between those centres, as well as between other places in the vicinity of the line, than any of the other schemes submitted to them.

The cost of construction, equipment, working, and maintenance of such a railway, intended for goods only, would undoubtedly be much less than that of the existing lines, which were constructed and are used for passengers and goods jointly; and it appears perfectly clear that goods could be conveyed on such a railway at rates not only far below those now charged, but which, it is authoritatively stated, would leave a loss to the present lines.

The Committee have already pointed out wherein Colonel Holme's scheme might be improved to meet the requirements of local trade; they understand, however, that Colonel Holme is further considering the matter, and will issue a revised scheme, which the Committee hope to publish as a supplement to this Report.

The Committee finally recommend:—

(1) That Colonel Holme's revised scheme should be carefully examined, and, if approved of, should be adopted; and that steps should then be taken to obtain the effective support of the commercial community to such undertaking, or to any further modification thereof which it may hereafter be found desirable to adopt.

(2) That in order to ensure the success of the undertaking it is important not only that the necessary capital should be obtained at the lowest possible cost, but also that the railway should not, when completed, fall into the hands or under the control of the existing companies; and, to this end, the scheme adopted should be placed before the Liverpool and Bootle Corporations and the Mersey Docks and Harbour Board, and their co-operation obtained in guaranteeing the interest on the necessary outlay, and in taking measures to ensure the maintenance of the line as an independent concern.

Note.—*The Lurry Platform Carrier Railway.*—Notwithstanding the result of the interview with the railway managers, the Committee are still strongly of opinion that considerable economy might be effected by the use of the Lurry Platform Carrier, especially upon a goods railway such as that recommended above.

Approved by the Committee, Friday, 22nd July, 1898.

George H. Cox, *Chairman of Committee.*
Thomas H. Barker, *Secretary.*

After the Committee have had an opportunity of considering Colonel Holme's revised scheme, a supplement to the Report will be issued which will contain that scheme and the final recommendations of the Committee thereon.

* Proposers of schemes.

MESSRS. TOWARD & CO.'S MOTO-TRACTOR.

We take the following interesting account of this vehicle from the *Newcastle Daily Chronicle* of the 9th inst.:—

At the recent show of the Northumberland Agricultural Society in Newcastle, Messrs. Toward and Co. exhibited a steam moto-tractor, entirely designed and constructed by them. It was finished somewhat hastily for exhibition at the show—where it attracted much attention—and, though it had been tried on the road, its full capabilities were not adequately tested till Saturday, the 30th ult., when, attached to one of the Stanhope Street buses in daily use in this city, carrying a load of 30 passengers and the driver, it went through from Newcastle to Durham without a single stoppage for water or anything else, performing the journey of over 14 miles in two hours, and returning after a most satisfactory run. This Toward tractor, which is of 25 I.H.P., is one of the first vehicles of this description built under the (Light) Locomotives on Highways Act of 1896. The rear end of the tractor can act as the fore-carriage of any four-wheeled vehicle, so long as the combined weight of the tractor and the vehicle does not exceed a maximum of 4 tons unladen. The turntable is adjustable in height, being raised or lowered as required by a hand-wheel and screw. The tractor is built of steel, and is capable of drawing a load of 3 tons on a good average road. The steam is raised in a horizontal water-tube boiler, coke-fired, the working pressure being 200 lbs. and the test pressure 400 lbs. per square inch. The engines are compound inverted, reversing, and run at about 400 revs. per minute. They are geared on to the driving wheels at 6 to 1 and 3 to 1 respectively for the two speeds of four and eight miles an hour. The tractor is fitted with two powerful independent brakes, one a pedal band-brake acting on the intermediate shaft and the other a screw brake of spoon pattern acting on the driving wheels. With this brake power the tractor can be brought to a stand with a full load on any hill. Differential gear is fitted for turning the vehicle, the front axle being pivoted at each wheel, thus dispensing with a fore carriage and turntable. Coke lockers are at each side of the boiler and tool lockers in front, a shelter being provided over the driver's seat. The water is carried in a tank underneath the platform at the rear of the tractor, and sufficient water is carried to take the vehicle 20 miles without a stop.

This tractor has been purchased by Mr. George Handyside, of Newcastle, for the purpose of running a passenger vehicle in the country, and the journey on the 30th ult. referred to, over the hilly road to Durham and back with the large bus carrying 20 passengers inside and 10 outside, was in the nature of a trial trip.

Drawing its full load, the tractor left Newcastle shortly before four o'clock, and, the weather being fine, and the journey being made in good time, the run through the country was much enjoyed. The population *en route* turned out in large numbers to witness the novel sight as the tractor drew its freight through the villages. All the banks were tackled without the slightest trouble being experienced in mounting them, and the machinery acted splendidly throughout the journey. At Durham a fresh stock of water was taken aboard from the fountain in the Market Place, where large numbers of people congregated around the vehicle, and submitted it to a close and curious inspection. Durham had been reached shortly before six o'clock, and after a stay in the Cathedral city of about two hours, the passengers once more took their seats. The spectators seemed to be delighted to see the huge vehicle turned round in almost its own length, and as the tractor steamed out towards Newcastle down the narrow street and over the bridge which crosses the Wear, there was a perfect sea of faces on all sides. The crowd appeared to be intent on seeing how the vehicle would surmount the steep and long incline leading out of Durham with such a load. This task, however, was accomplished with ease, and then the tractor headed at a smart pace for Newcastle. A stoppage was made at Chester-le-Street on behalf of the human freight, the mechanical part of the concern needing no attention, and Newcastle was reached about 10.15. It was found on the journey that the tractor could and did travel for a short distance—which might have been prolonged —at a higher rate of speed than that allowed by the Act. On the termination of the journey it was the unanimous verdict of the passengers that the motor-car is coming to stay, and is now coming very fast.

Messrs. Toward and Philipson were of course delighted at the realisation of their anticipations in this trial, for the Durham road is one well calculated to test the capabilities of the tractor; and it may be added that Mr. George Handyside, who has bought the vehicle, is also enthusiastic about its promise for the future. He, we understand, proposes to run it attached to an omnibus which Messrs. Atkinson and Philipson are to build—on the road between Newcastle and Hull, *viâ* Sunderland and Stockton, carrying passengers between the different towns and villages *en route*, at the rate of ½*d*. per mile. Should the experiment justify Mr. Handyside's hopes of success, a very large number of tractor vehicles will be ordered from Messrs. Toward and from Messrs. Atkinson and Philipson, and the service will be extended to other districts of the North of England.

AUTOMOBILISM v. DEAR FORAGE.

In an instructive leading article on the 10th inst., dealing with the figures of both the London General Omnibus Company and the London Road Car Company, the *Financial Times* draws attention to some very pertinent points in both Companies' balance sheets. In the course of some critical remarks, our contemporary says:—"At the present juncture, when the motor-car and the motor-cab have become recognised as permanent institutions on the streets of London, when they no longer excite the jeers of the gutter urchin or the sarcasm of those ultra-conservatives, the cabby and the bus driver, we are reminded by the reports of the two great London Omnibus Companies that the horse still holds the field as the main factor in street vehicular locomotion, though this monopoly has certainly been slightly trenched upon in these latter days. . . . . From 1893 to the first half of 1895 the London General Omnibus Company paid dividends at the rate of 8 per cent. per annum. The next three distributions were at the rate of 9½ per cent. per annum, while lately the return has been at the rate of 10½ per cent. The London Road Car Company distributed at the rate of 6 per cent. from the first half of 1894 to the second half of 1895; in the following half-year 8 per cent. was paid, then 7 per cent., 10 per cent., and 8 per cent., while 8 per cent. was also the announcement for the last half-year." The article concludes with the following well-timed warning:—"The record for both is, therefore, very satisfactory, but we doubt if the progress in distributions will be maintained in the future. On the contrary, we are inclined to think that, whatever may be the course of gross receipts, the high-water mark of dividend-earning power has been nearly, if not quite, reached for the present. Much of the extra expenditure recorded in the last report or two is of a permanent nature, while it is extremely unlikely that the cost of forage will fall again to the figure of two years ago. As regards competition, the Companies need not fear the rivalry of Mr. Lawson's steam-omnibus, but they will certainly have to take into consideration the growing vogue of self-propelled vehicles. A year or two ago a London General Omnibus director, in reply to a question put to him at a general meeting, remarked that he "had his eye" on these motors. It is to be hoped that he has not relaxed his vigilance, for it is from that quarter that competition is most likely to arise."

We hope for the sake of their shareholders these Companies will not, like the Fire Brigade Committee of the London County Council, "wait and watch" too long, but wisely invest some of the present profits in trying for themselves what automobilism can do to solve the difficulty of "cost of forage."

These remarks should with greater force commend themselves to the notice of the Glasgow Tramway and Omnibus Company, whose affairs appear to be in a very unsatisfactory state—simply on account of "dear fodder." The report of this Company for the past half-year states that although the gross receipts were £73,300 for the period, it only managed to secure £9,916 in net revenue. There is, of course, no dividend, and the directors attribute this lamentable result to the high price of provender.

REVIEWS OF BOOKS.

"On an Autocar through the Length and Breadth of the Land." By HENRY STURMEY, London and Coventry.

THIS is a capital account of a tour made last year through Great Britain by the author on a Daimler motor-vehicle, which he prefers to call an autocar. Mr. Sturmey's account of his experiences form most interesting reading; he has acted as a kind of automobile apostle carrying into remote districts the gospel of automobilism, and showing to farmers and others how much quicker, safer, and more comfortable is a well appointed motor-vehicle than the ordinary horse-drawn carriage. To undertake such a long journey was a feat requiring considerable courage and self-reliance, as in many districts the local public opinion, or, as we prefer to call it, bucolic instinct, is opposed to all change, and would as readily smash up a motor-vehicle as the Chinese destroyed the Wosung Railway—from sheer angry ignorance. Mr. Sturmey seems to have had one or two hostile demonstrations to contend with, but happily without anything serious resulting. As a record of the first long distance journey undertaken in this country, his work will have a distinct historical value. Mr. Sturmey writes in a plain style of good English, and being an expert cyclist and, let us add, automobilist, his account is not alone interesting, it is also instructive. We have pleasure in recommending the work.

The Engineering Magazine for August is before us and, as usual, its contents are of a high class character, but not of much interest to automobilists. Pressure on our space forbids any extended notice.

La Revue de Méchanique.—The July number contains an excellent and useful article on pumps by M. Maase, which may be read with advantage by automobilists, and one on the condensation of steam in steam engines, by the distinguished English engineer, Mr. Bryan Donkin, one of the judges of motor-vehicles at the late Birmingham Agricultural Show.

WE have also received:—*Science Abstracts*, *The Journal of the Society of Arts*, *The Indian Engineer*, *Industries and Iron*, *The Practical Engineer*, *Transport*, *Coach-Builders' and Wheelwrights' Art Journal*, *The Journal of Acetylene Gas Lighting*, *Knowledge*, *Machinery Market Review*, *Phillips' Monthly Machinery Register*, *The London Chamber of Commerce Journal*, *Indiarubber World*, *Cyclist*, *Scottish Wheel*, *Irish Field*, *The Yachting World*, *The Engineering Magazine*, *La Revue de Méchanique*, *La Locomotion Automobile*, *La France Automobile*, *L'Industrie Velocipédique et Automobile*, *L'Automobile Illustré*, *La Moniteur Automobile*, *La Revue des Transports Parisiens*, *Les Sports*, *L'Energie Electrique*, *Der Motorwagen*, *Samokat*, *Horseless Age*, *American Wheelman*, *Transactions of the American Society of Mechanical Engineers*, *Transactions of the American Institute of Electrical Engineers*, *Journal of the Western Society of Engineers*, *The Motocycle*, *The Scientific Australian*, *The Austral Wheel*, *Australasian Coach-Builder and Saddler*, &c., &c.

LAW REPORTS.

Lamina Accumulator Syndicate.—Before Mr. Justice Kekewich, in the Chancery Division, on July 22nd, Mr. Warrington, Q.C., mentioned the matter of the Lamina Accumulator (Elieson's British Patents) Syndicate (Limited), and the Elieson Lamina Accumulator Company (Limited), in which he had a motion on behalf of the Earl of Galloway for the appointment of a receiver. It stood over to enable arrangements to be made by the Company in the terms of the agreement to issue to the Earl of Galloway debentures in place of the debentures he held in the Syndicate. He understood that the new debentures had been sealed the previous night, and had now been handed over to the Earl, who had given his undertaking to hand in the old debentures. Under these circumstances he now proposed to stay further proceedings in the action. He understood it was arranged that defendants should pay the costs. Mr. Bramwell Davis, Q.C., on behalf of the defendants, said the assignment to the new Company had been completed only the previous day, and arrangements for the exchange of the debentures were at once made. He was not instructed to agree that defendants should pay the costs. Mr. Warrington: Then all I can agree to is to take no order, except that costs be costs in the action. Mr. Justice Kekewich: I think Mr. Warrington is right, and then whoever is wrong in the action will have to pay the costs. Order made accordingly.

Police Court Proceedings.

A Bank with £7 Capital.—Edward Alexander Bremner, 31, clerk, pleaded guilty, at the Central Criminal Court on July 26th, to stealing cheques belonging to the Motor Manufacturing Company (Limited), of Holborn. Mr. Sherwood, who prosecuted, said that Bremner, who was clerk to the secretary of the Company, opened an account with a bank, called the Bank of Great Britain (Limited), through which he passed the cheques. This bank had a paid-up capital of £7, with power to extend to £1,500,000. The nominal shareholders were clerks in the office. The Recorder: Does this bank still exist? Mr. Sherwood: I do not know, my Lord; the premises were being changed when this case was before the magistrate, who used some strong observations respecting the bank. The Recorder: I do not wonder at that. Prisoner was sentenced to 12 months' hard labour.

Furious Riding.—Frank Cundy, of Great Portland Street, was before Mr. Curtis Bennett, at the Marylebone Police Court on July 28th, on a summons for furiously riding a motor-quadricycle to the common danger, at the Inner Circle, Regent's Park, on the 17th ult. The defendant pleaded guilty, and in reply to the magistrate said he was going at the rate of 12 miles an hour. Mr. Curtis Bennett (to the constable): What rate do you say he was going at? Constable: A good 19 miles an hour. I timed him. Defendant: I didn't think it would go so fast. Mr. Curtis Bennett: It was better than you thought for. The defendant was fined 10*s.*, with 2*s.* costs.

Sweet are the Uses of Advertisement.—At the Bradford Police Court, Albert Farnell, cycle dealer, was prosecuted for riding without a light. The defendant did not appear. It was, however, stated that he told the police that they would do him a kindness if they would summon him, as it would be a good advertisement for him. He was fined £1 8*s.*

Bankruptcy Court.

Re Fleet Cycle Company (Limited).—In the same Court Mr. Eustace Smith, on behalf of the Perfecta Seamless Steel Tube Company (Limited), presented a petition for the compulsory winding up of this Company. The petitioners were judgment creditors for £995 12*s.* 1*d.* There was no opposition, and his Lordship made the order asked for.

Re Cycle and Motor Accessories Company (Limited).—Mr. Ashton Cross, on behalf of Mr. F. T. Mawby, a judgment creditor, applied for an order on July 20th for the compulsory winding up of this Company. Counsel stated that his client's debt was for £106, and he had made frequent demands for payment, but without result. The Company had passed a resolution for voluntary winding up, and one of the liquidators supported the present petition, while the other had stated that he would do nothing until he saw what his Lordship did. Mr. Justice Wright made the usual compulsory order.

FOREIGN NOTES.

At Liège a Company has been formed with a capital of two millions of francs to undertake the manufacture of moto-vehicles.

The Paris Exhibition of Moto-Vehicles realised a net profit of 40,000 francs. Similar exhibitions in London have uniformly been run at a loss.

The Société des Industries Electriques is preparing a map of France upon which will be indicated the electrical stations where charging can be effected.

The Daniel Augé Company has been formed at Levallois with a capital of £4,000, in order to manufacture moto-vehicles using a light oil-motor known as Le Cyclope.

The Société des Transports Automobiles de Chalon sur-Saone has been formed with a capital of 200,000 francs. A company is also being formed called Le Société d'Études d'Omnibus et des Voitures Automobile.

It is said that the Paris Omnibus Company, which has a monopoly of the omnibus traffic in Paris, is about to contract a loan of £1,000,000 for the purpose of transforming its present rolling stock, and introducing motor traction.

On the 21st inst. there will be a race for motocycles, not exceeding 440 lbs. weight, organised by L'Union Vélocipèdique Tourguennoise, from Tourcoing to Béthune, and on the same date and the following day there will be a race from Bordeaux to Biarritz.

It is said that the Paris Omnibus Company has decided to establish two electric generating stations—one at Vincennes, of 4,000 H.P., and one at Billancourt, of 5,000 H.P., and they intend trying every form of electric traction known before adopting a general system.

From Berlin we hear that a large number of electric cabs are to be put in service by the Berliner Fuhrwesen Gesellschaft. A large building is being erected to serve the purpose of a cab shed and accumulator charging station; the current being taken from the mains of a neighbouring electricity supply station.

It is said that the Paris Cab Company has paid £47,000 to the London Electric Cab Company for the French patent rights of the latter. We have not been able to verify this statement, and think it a very doubtful one. It is also said that this same French Cab Company has placed an order for 200 cabs. This is also doubtful.

Les Poids Lourds Competition will take place at Versailles from October 6th to 12th next. The routes and general arrangements will be the same as those followed last year. M. Forestier will conduct the trials. Being limited to vehicles carrying as a maximum but 1 ton of useful load, these trials will not be of much interest to those engaged in heavy traction.

A serious accident marked the opening of the season at Trouville. A lady, Madame Bonnevaux, and her two children, were driving along the Route de la Corniche when their horse took fright at a moto-vehicle driven by M. Bizet, a son of the famous composer of "Carmen." The carriage was upset, and Madame Bonnevaux sustained injuries from which she died in the course of the night.

A French automobilist was recently convicted of the offence of furious driving and fined 50 francs. He appealed; the Court, finding from the evidence that the appellant had failed to provide himself with suitable sound signals and while thus improperly equipped had run over a man, rejected the appeal, increased the penalty to a fine of 200 francs, and condemned the appellant to eight days' imprisonment—and we are not at all disposed to say that justice was not done.

In the recent race for moto-cycles from Tours to Blois and back the winner was M. Jamin, who did the distance of 62 miles in 1 hour 53 minutes, or at the astonishing rate of 32·63 miles per hour. M. Jamin was the winner, it will he remembered, in the Paris-Dieppe race last year. The next hest time was made by M. Marot in 2 hours 14 minutes, while Carhuratuer was third in 2 hours 21 minutes. There were 15 starters, and 12 did the whole distance.

A tramway is at work in Denver, Colorado, which possesses a feature of novelty in passenger transport. The line is about a mile in length, and has a gradient averaging about 3½ per cent. Horses are employed to supply the tractive force on the up journey, and gravity supplies the means for returning the cars and passengers, the horse riding on the platform. The company owns one car and five horses, and the daily mileage is about 40. The horse is able to draw the car up the grade at an average speed of about 2½ miles per hour, and the car descends by gravity at a rate of about 15 miles per hour.

There was an automobile contest at Lille in the early part of the month, when 15 competitors entered for a race to Calais and back. Nothing remarkable in the way of speed was accomplished, owing to the bad state of the roads, which caused some competitors to abandon the contest. The winners were M. Kreutler, in a Peugeot; M. Marcellin, on a De Dion moto-tricycle; M. Giradot, on a moto-bicycle; M. Barden, on a De Dion moto-tricycle; M. Deschamp, on a Panhard voiture; M. Vallée, on a Vallée voiture; and M. Rossel, on a Rossel voiture. The contest was inaugurated by the Société Industrielle de Lille, and was, on the whole, a successful function.

The Paris police have recently received many complaints against a man who has invented a system of taking advantage of the comradeship which exists among hicyclists on the road. The man in question is a tall, strong fellow, who speaks with a slight foreign accent. His costume—cycling, of course—is always a model of elegance. Cyclists find him sitting disconsolately by the roadside with a punctured tyre, and are appealed to for assistance on the plea that he has forgotten his repairing outfit. Good Samaritans alight, and while they are examining the injury to the hroken-down old machine at the roadside the elegantly-dressed person butts them violently with his head, and by the time they have recovered he is far away on his would-be benefactor's hicycle.

Automobilists in France, or rather that section that finds a delight in furious driving, are just now much exercised at the severe attitude adopted towards them by the civil authorities. In the late Paris-Amsterdam race the competitors who exceeded the eight mile per hour limit in the Seine department were much harassed by the police, and much ill-feeling has heen engendered therehy. Baron Rogniat, who made arrangements for the race, has even gone to the length of addressing a remonstrative letter to the Prime Minister, begging him in the first place to cause his subordinates to assume a less aggressive attitude towards the drivers of moto-vehicles, and in the second to give orders for an adequate series of rules to he drawn up regulating motor traffic in France. In the meantime existing regulations are being stringently put into force.

Says the Paris correspondent of the *Daily Chronicle* in a recent issue:—In Paris the municipal body is still much exercised about the regulation of street traffic, which undoubtedly presents difficulties even greater than those we have to contend with in London. Not only do lively duchesses and exhilarated men of fashion drive autocars at a pace dangerous to the public safety, but the tram companies link three or four carriages together and launch them in the thoroughfares with a speed that puts to shame many French express trains. Moreover, the desire for minute legislation, so familiar a weakness of our neighbours, has given rise to bye-laws enough to fill a thick volume. Nor can any cabman or carter he expected to have this portentous code at his fingers' ends. The latest suggestion is to erect at all crossways a sort of kiosk, on the top of which shall he seated a policeman in a revolving chair. He is to he provided with signboards, on which are painted "Halt," and other words of command, and these he will exhibit in different directions as occasion may require. The idea is by no means had, but one doubts whether Paris jehus will he controlled by a method so simple and reasonable.

In order to cope with the extension of automobilism in Paris, and to see that the moto-vehicles and drivers conform in all respects to the law, an inspector is to he appointed, and the examination of candidates will take place on September 3rd next. It is indicative of the intensely bureaucratic methods of French officialism to consider the qualifications, &c., required of these candidates. An application has to be made by a candidate to the Préfect of Police, accompanied by a hirth certificate, military good conduct certificate, certificate from the judge of the district as to character, &c. A medical examination has to be gone through, any trace of heart disease being a disqualification, and then a technical examination in various branches of applied science connected with automobilism. The candidate has, in fact, to pass an examination quite as stiff, if not more so, as is required by our Board of Trade for the rank of chief engineer. He has to he practically conversant with the use and handling of steam, oil, and electric motors, and the repairs to them. In order to obtain this extensive course of knowledge the candidate must have worked hard hoth in the shops and at the technical schools. The fortunate winnor of this municipal appointment will receive the truly munificent salary of £120 per annum.

HORSE AND MOTO-VEHICLE ACCIDENTS.

Killed by a Runaway Horse.—On the 5th inst., at the Camberwell Coroner's Court, the Deputy Coroner held an inquest on the body of Herbert George Ladhrook, aged 11 years, the son of a hoot finisher living at Peckham, who was killed by a runaway horse. The father said that about half-past four o'clock on the 2nd inst. he was walking along Church Street, Camberwell, accompanied by his wife and two children. He stopped to look in a shop window when he heard shouts. As he turned round a horse and trap came full gallop along the pavement and knocked them all down. Witness, who was somewhat dazed, picked up deceased, who was bleeding from the mouth, but some gentlemen took the boy from him and carried it to the police station, which was opposite, where it was seen by a doctor and pronounced to he dead. His wife and daughter were also examined by the same medical man and taken home. F. Sheppard, a tar pavior, of 17, Melton Road, Southend-on-Sea, said that the horse and trap was his property. On that afternoon he left the animal in charge of a boy outside Bright's Coffee House, Church Street, while he went inside to partake of some refreshment. While seated there he heard the horse scrambling on the pavement. He rushed out, seized hold of the reins, but the animal hroke away. Witness was knocked down and one of the wheels of the vehicle passed over his shoulder. He saw nothing of what afterwards took place. When he entered the shop he removed the hit from the horse's mouth so that it could eat hetter. The jury, in returning a verdict of "Accidental death," added that there ought to be some regulation with regard to leaving horses in the streets without the bit in their mouth.

A Motor-Vehicle Turns Over.—On the 20th ult. as Mr. Hutton, of the firm of Hutton and Walker, electrical engineers, of Scarborough, was riding in a motor-vehicle in the direction of Whitby, accompanied by one of the employés of the firm, the wheel of the car came off as the descent of a hill about a mile from Scalby was heing made. The vehicle was going at a good speed at the time, and it turned over completely two or three times, and then Mr. Hutton and his man were seen to crawl out from underneath the machine. Fortunately, beyond being bruised and shaken, neither of them was seriously hurt, and Mr. Hutton borrowed the hicycle of a visitor, who witnessed the accident, and rode into Scalby for a dray to cart off his broken vehicle.

The Vagaries of the Horse.—An extraordinary accident lately occurred in Paris at the Pont de la Concorde. A horse, while dragging a heavy load of wood along the hank of the Seine, had shied, and in its fright had rushed over the stone roadway bordering the stream. Instead, however, of falling into the river, it hung suspended in mid-air, kept in position by the weight of the cart to which it was attached. For a long time all the efforts made to rescue the animal from this strange predicament were unavailing. The firemen, who in Paris are appealed to in all sorts of emergencies, were called to the scene, hut just as they arrived the horse hroke the shafts by its frantic struggles and fell into the water. A fireman at once lassoed it and it was at last landed, apparently not much the worse for its somewhat exciting bath.

CORRESPONDENCE.

**** *We do not hold ourselves responsible for opinions expressed by our Correspondents.*

**** *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion, or containing queries.*

**** *Correspondents are particularly requested to write on one side of the paper* ONLY, *to place the subject of their letters as a headline at the top of the sheet, and their names and addresses at the foot. Attention to these matters saves much time and ensures the insertion of the letter.*

THE LOCOMOTIVES ON HIGHWAYS ACT.

To the Editor of THE AUTOMOTOR.

SIR,—I presume it is needless to assure you that I have followed your account of the Liverpool Heavy Motor Trials with the keenest interest. I notice, as the outcome of the trials, that it is advocated to approach Parliament as to a revision of the Highways and Light Locomotive Act of 1896, with a view to either putting no restriction on the total weight of a light locomotive or increasing the maximum weight of the vehicle from 3 to 4 tons.

Although it would appear from the recent Liverpool trials that the maximum carrying loads and speeds in these tests demand the increase of the weight of the vehicles in order to satisfactorily comply with the conditions, I hardly see that these trials should be considered as conclusive, and I certainly think, before any decisive step is taken to bring about an alteration in the recent Act, that some time should elapse in which to gain more experience on the subject.

So far, I think, one has but little complaint to make about the various conditions contained in the new Act, which, whether by fluke or otherwise, is certainly all that one could have desired from legislators, considering the knowledge, experience, and advice then at their command.

I think I should also frankly confess that I myself am partly responsible for the 3-ton clause, knowing by experience that oil-driven vehicles, for instance a Daimler lorry such as illustrated in your June issue, can easily carry a load of 5 tons at an average speed of eight miles per hour, with a tare weight well under 3 tons, and yet give general satisfaction.

The Act, as it exists at present, will certainly be a stimulant to steam power when applied to heavier vehicles on common roads.—Yours faithfully,

FREDERICK R. SIMMS,
Consulting Engineer.

FERRY RATES ON MOTOR-VEHICLES.

To the Editor of THE AUTOMOTOR.

SIR,—We think it well to warn motorists to avoid the ferries at Granton and Queensferry. One of our cars crossed at Granton about a week ago and we were charged 10*s*., the boat taking 20 to 30 minutes to cross, and at Queensferry—half the distance—5*s*. We have had the matter up with the railway company and they refuse to give us any redress. The matter should be referred to the Board of Trade, and if you can help us, and say how to proceed, where to write to, we shall esteem it a favour.—Yours faithfully,

EDINBURGH MOTOR CAR COMPANY,
John Love, Manager.

[There is no doubt that the charge is excessive and illegal, because Parliament, in granting powers to railway companies, never contemplated the possibility of the construction of light road motor-vehicles, and certainly never intended that these latter should be discriminated against by a company that runs heavy motor-vehicles. To obtain redress is, however, another matter. You might lay the case before the Railway Commissioners, the Board of Trade Railway Department, and the Local Government Board, but we doubt whether these bodies can or would do anything. You might, however, do some good by laying the case before the Automobile Club. Sooner or later this body will have to take steps to fight the railway companies on this very important point. You could by litigation compel the company to justify their charge, but unless you are backed up by the bodies referred to this course would not be advisable, unless you were prepared to take the case as far as the House of Lords, and we fear that this will have to be done before the railway companies will place motor-vehicles upon the same footing as ordinary ones. We shall be glad to know what action you take.—ED.]

THE CONSUMPTION IN SPIRIT MOTOR-VEHICLES.

To the Editor of THE AUTOMOTOR.

SIR,—I read in your interesting July number, under "Notes of the Month," about the serious doubts you entertain concerning Messrs. Sutton Brothers' motor-cycle having accomplished 400 miles on 4 gallons of oil.

Although this statement concerning the consumption of oil seems pretty low, I do not think it is impossible for a motor-bicycle fitted with a motor of about ¾ H.P.; but your conclusion that Messrs. Sutton's motor-cycle should consume 40 gallons of oil for 400 miles I am afraid is entirely wrong, and the French minimum consumption of spirit (benzine, petrol, or naphtha) of ·8 pint, as quoted by you, cannot possibly refer to a motor-cycle.

An ordinary De Dion motor-tricycle will cover about 100 miles with 2 gallons of oil, according to my experience, and I believe it is possible to do even more under favourable circumstances.—Yours faithfully,

FREDERICK R. SIMMS.

[We have made a clerical error. For ·8 read ·18. The consumption in spirit motors varies from ·12 to ·2 pint of petrol per mile for motor-tricycles, and is about ·6 pint per mile for vehicles of 4 H.P. —ED.]

"SIX-WHEELERS."

To the Editor of THE AUTOMOTOR.

SIR,—By your courtesy I have at various times urged the adoption of *six* wheels for heavy motor-vehicles, instead of the usual four, and I have now the pleasure of enclosing a very rough sketch of the general appearance of such an arrangement, which at any rate cannot be described as "horseless." As a work of art, and in the matter of technical details, the picture has, I am aware, many

defects, but it will, I think, serve the purpose in hand. A heavy motor-vehicle should in fact, as it seems to me, be built on the lines, not of a cart, but of a railway locomotive, for which the original four wheels were soon found quite insufficient.

The advantages of the proposed adaptation are:—

1. Increased accommodation, the vehicle remaining as flexible and easily steered as one of half the length;

2. A reduction in load per axle (which item, by the way, should be considered of more importance in legislation than the gross weight);

3. Probably increased safety, as the loss of a wheel would not prove so disastrous as in the case of an ordinary omnibus, for instance; and last, but perhaps not least,

4. Absence of patent rights, vendors, &c.—I am, &c.,

ALFRED J. ALLEN.

London Institution, E.C., *August 5th.*

FOUR OR SIX WHEELS?

To the Editor of THE AUTOMOTOR.

SIR,—In reply to your correspondent, *re* the Liverpool Trials, it would be interesting to know why he singles out the "Lifu" lorry to compare with Thornycroft's six-wheeler. Is he ignorant of the fact that every other lorry competing had four wheels only?

He says the six-wheeled lorry is obviously superior to the "Lifu No. 1," in its steering capabilities, whereas everyone who was present at the trial knows that the four-wheeled lorries went through their steering tests more satisfactorily than did the six-wheeler.

With regard to trailing steerers, where is the *practical* engineer who would think of fitting a motor-vehicle with a combination of gear to attain a very doubtful advantage of trailing steering wheels? Is Mr. J. Allen copying locomotive practice when he mentions trailing steerers? If so, it shows how little he understands that class of engine.

Perhaps he would advocate wheel coupling rods. A motor-vehicle must be built to turn in comparatively narrow roads, whereas a locomotive has its course made.—I am, yours truly,

GEO. COOMBS, *Engineer.*

60, Cobden Road, Brighton, *July 30th.*

Motor v. Horse-drawn Omnibuses.—Every single experience so far, both in France and England, even with inferior systems, has demonstrated the superiority of motor-vehicles, from the financial point of view, to horse-drawn ones. When we see that the London General Omnibus Company can pay over 10 per cent. dividend with its obsolete means of locomotion and dear fares the conclusion is obvious that given well designed, comfortable motor-vehicles and cheap fares, a constant and high dividend is beyond doubt.

The Motor Carriage Supply Company (Limited).—We understand that this Company, whose offices are at Donington House, Norfolk Street, Strand, London, W.C., are prepared to take orders for motor carriages and motor cycles of all descriptions, their speciality being Daimler motor carriages of special type and latest development, made at the works of the inventor, M. Daimler. These latter, we are informed, they are empowered to deal in under a special arrangement with the holders and the licensees of the English Daimler patents.

Automobilism and the Fire Brigade.—Our recent utterances on the question of motor fire-engines seems to have attracted a good deal of attention in various quarters, and the public is slowly grasping the idea that in large cities, at any rate, every purpose served by the horse can be much cheaper and more efficiently performed by the motor-vehicle. In some apparently inspired criticisms we are assured that the Fire Brigade authorities are "playing a waiting game. They are watching closely everything that is being done, and are ready at all times to examine, enquire into, and experiment with any practical vehicles presented to them." Exactly; we know that all officials always do play a waiting game. They are always "watching." Yes, but the public pays them to originate, devise, and improve. We can all watch and play a waiting game, and if we all did so no improvement of any sort would take place. If we carried this principle of watching and waiting into practice we should have no inventions of any sort. Watching and waiting was the excuse of the man who hid his talent in the earth. *He* was waiting for the grand opportunity. It is poor philosophy to watch and wait; it is nobler to *do*, as Carlyle would say. Why, if we had watched and waited for the perfect railway locomotive, the perfect sewing machine, the perfect typewriter, the perfect battleship, we should still be without these useful articles. This watching and waiting policy on the part of the Fire Brigade has been carried on for years with the result that plant that was out of date a quarter of a century ago is still faithfully copied. Thus high-pressure steam (according to modern ideas), modern pumps, liquid fuel, petrol and electric motor-pumps, worked off leads taken from the nearest street junction box, chemically charged streams, are all things of which the London County Council Fire Brigade has not the remotest conception or experience of. Yet the brigade is watching and waiting—naturally! What else could it do? Do let us see the Fire Brigade justify itself by examining the question and not watching and waiting. Two of our most worthy novelists in the *Golden Butterfly* relate how two men were always watching and, of course, like the Fire Brigade, "playing the waiting game." They alas! watched and waited so fervently that when the time to work arrived their night had also arrived, in which we are told "no man can work." *Verb. sap.*

Specifications Published.

THE following is a List of Specifications recently published, and obtainable at the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform charge of 8*d*. per copy. Owing to the enormous pressure upon our columns it has been found impossible to deal in any other form with the accumulation of patents now being taken out in connection with automobilism. As far as possible, a selection for special mention is made by the Editor from the more prominent inventions:—

Applied for during 1897.

12,046. J. J. ELLIS, 5, Hargreave Terrace, Rathgar, co. Dublin. Motor cycles.

12,158. G. KIRBY, 50, Myddleton Road, Bowes Park, London. Variable speed gear.

12,199. C. M. JOHNSON, Broad Street House, London, E.C. Fluid pressure apparatus for generating, storing, and transmitting power.

12,443. A. WERNER and P. DE KILDUCHEVSKY, 49, Bernard Street, London, W.C. Electric accumulators.

15,348. F. R. SIMMS, 12, Norfolk Street, Strand, London. Exhaust valves.

16,977. W. J. H. JONES, 134, Gladstone Road, Sparkbrook, Birmingham. Ignition device.

12,553. E. ROSSEL, 82, Rue des Sarrazins, Lille (Nord), France. Petroleum motors.

12,783. J. H. BLAKESLEY, 53, Victoria Street, Westminster, S.W. Gearing.

12,942A. M. JOHNSON, 22 and 23, Laurence Pountney Lane, London. Electric igniting apparatus.

13,161. C. E. CALLOCH, La Fleche (Sarthe), France. Internal combustion engine.

14,535. J. WATKINS, 120, St. Aldate's Street, Oxford. Oil or spirit vaporising apparatus.

17,258. G. W. Mohrstadt, 44, Bradford Street, Birmingham. Locking arrangement.
17,533. G. R. Blot, 16, Rue Drouot, Paris. Differential gear.
17,839. W. Hornsby and R. Edwards, Spittlegate Ironworks, Grantham, Lincoln. Explosion engines.
13,097. J. Hoare, 317, City Road, London. Brake.
17,226. H. A. Lamplugh, 61, Wellington Road, Birmingham. Motor carriages.
17,317. E. Petreano and J. Bonnet, 95, Boulevard Beaumarchais, Paris. Gas and hydrocarbon engines.
18,804. E. Petreano, 95, Boulevard Beaumarchais, Paris. Reversing gear.
13,610. H. H. Lake (La Société Mari Giusli and Co., Padua, Italy). Motor-car for propelling road vehicles.
13,998. G. E. Whitney, 88, Falcon Street East, Boston, Mass., U.S.A. Gear cases.
14,150. W. W. Beaumont and H. P. Holt, Outer Temple, 222, Strand, W.C. Steam generators.
14,220. A. F. Scott, 27, Welbury Drive, Bradford, Yorks. Steam and other fluid pressure engines.
16,816. H. Leitner, 207, Piccadilly, London. Secondary batteries.
14,910. H. W. Headland, 77, Chancery Lane. Electric motors.
15,665. T. W. Drabble, 18, Hertford Street, Coventry. Autocars.
16,508. C. M. Turrell, 111, Hatton Garden. Starting cranks.
16,755. F. J. Burrell, 67, Corporation Street, Birmingham. Steam generators.
19,910. W. T. Rowden, Lenzie, near Glasgow. Internal combustion engines.
22,606. J. H. Rosenthal, 62, St. Vincent Street, Glasgow. Water tube steam generators.
15,914. J. H. Rosenthal, 62, St. Vincent Street, Glasgow. Water tube stesm generators.
18,176. A. Heil, 55, Chancery Lane. Accumulators.
18,780. W. Kay and W. H. Walker, 50, Cherry Street, Birmingham. Chain wheels.
19,918. A. Crossgrove, 6, Finkle Street, Stockton on-Tees. Fluid pressure motor.
21,738. O. Bomborn, 18, Southampton Buildings. Fuel feeding devices.
22,971. H. H. Leigh, 22, Southampton Buildings. Petroleum motors.
15,908. J. Katz, 57, George Street, Coventry. Explosion motors.
15,983. E. Uhlenhuth, 44, Rue du Bellay, Argers, France. Internal combustion engines.
17,776. E. J. Clubbe and others, 16, Elm Street, Gray's Inn Road. Wheels.
18,322. I. M. Collins, 70, Wellington Street, Glasgow. Crank driving mechanism.
20,389. W. Firman and A. Cave, 4, South Street, Finshury. Explosion engines.
20,446. A. A. W. Van Reede, 4, South Street, Finsbury. Steam or other fluid engine.
23,974. J. K. Carey, 33, Chancery Lane. Variable speed-gear.

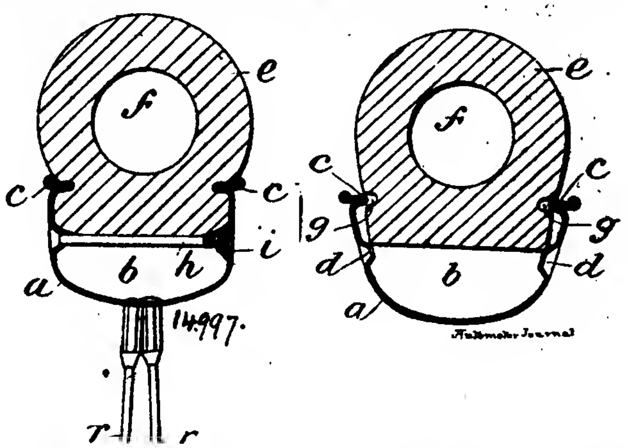
1898.

7,707. Norga. Carburating apparatus.
8,128. A. J. Boult (F. Hayot, 3, Rue de Coetlogon, Paris). Cylinder and piston motors.
6,394. R. H. Smith, Ellerslie, Brunswick Road, Sutton, Surrey. Generators of mixed gas and steam.
3,072. F. W. Meadway, 354, Bethnal Green Road, London. Mudguards and guards for machinery.
6,152. C. Caille, 53, Rue Rennequin, Paris. Rotary motors actuated by internal explosions.
8,785. S. Ballard, E. Ballard, and J. Goode, Colwall, Malvern, Worcester. Valve boxes of the vaporisers of oil-engines.
9,416. D. Timar, 27 and 28, Luisenstrasse, Berlin. Oil and gas motors.
10,134. A. Ball, Myrtle and Walnut Streets, Claremont, N.H., U.S.A. Direct acting fluid pressure engines.
4,677. E. Taylor, Pemberton Street, Warston Lane, Birmingham. Mode for making the junctions of motor-car and other frames so as to avoid brazing.
6,267. O. Obermeyer, Beatrice, Nebraska, U.S.A. Fluid pressure rotary engines.
7,955. V. E. Prétot, Avenue Philippe Auguste, Paris. Starting apparatus.

14,997. Rims and Tyres for Wheels. S. C. Davidson, Sirocco Engineering Works, Belfast, Ireland. June 21st, 1897.

Refers to rims and tyres for wheels, and particularly to wheels of carriages, bicycles, and other road vehicles, and the objects are to construct a light rim of great strength, and so that it will securely hold and support an indiarubber, leather, or other more or less elastic tyre, and to construct tyres specially adapted to fit within and be supported by the improved rims.

Referring to Figs. 1 and 2, *a* is the wheel rim curved outwards so as to form a continuous hollow or channel, *b*, around the outer face. *c c* are rim collars at the outer edges of the rim formed by flanging said edges inwards and then again outwards (the return or outward flange being optional). The inner edges of said collars, *c c*, are just sufficiently wide apart to allow the inner face of the tyre to pass between them (*see* Fig. 2). *d d* are a series of holes around both sides of the rim at about an inch apart, and preferably indented so as to form countersunk cavities as shown. *e* is the indiarubber or other tyre which may be formed either with a tubular air space, *f*, as shown, or with more than one tubular air space or solid. The inner face of the tyre is flat in cross section, or approximately so. In each side of said tyre is a continuous groove, *g*, to receive the corresponding rim collar or flange, *c*. *h* is one of the tightening-up bolts. When the tyre has been mounted on the rim, as shown in Fig. 2, the bolts, *h*, are passed through the rim from side to side and tightened up by the nuts, *i*; the outer edges of the rim are thereby forced inwards, and the collars or flanges, *c c*, are therefore gradually drawn in towards one another and become embedded in the grooves, *g g*, of the tyre. The tyre is thus securely and firmly attached to the rim, and its inner face is supported by the bolts, *h*.



Various modified forms are described and shown in the specification and drawings.

11,547. Hydrocarbon Motors. W. H. Casley, 97, Paris Street, Exeter, and A. F. Woodman, 2, Bartholomew Street, West, Exeter. May 10th, 1897.

This is an invention designed for measuring the oil charge for hydrocarbon motors.

A slide valve has a recess or small chamber the size of which may be adjustable. In one position of the valve this recess forms a portion of a passage or channel, by means of a port or ports in the surface or surfaces against which the valve slides, one end of which is in communication by any desired passages or valves with the explosion chamber of the motor, and the other end with any gas, preferably the atmosphere.

In a second position of the valve the recess forms a portion of a passage or channel, by means of a port or ports in the surface or surfaces against which the valve slides, in connection with the oil supplying the motor, and in this position of the valve a current of oil is caused to flow through the passage by gravity, or by having the oil in the tank and in the pipes leading to and from the passage in continuous circulation and heating one portion of the circuit and so causing a current, or by any suitable lifting or forcing device.

When in the first position the recess is cut off from the oil channel mentioned in the second position.

The slide valve is caused to move from one to the other position by any suitable gearing in connection with the motor, and is in the first position during at least a portion of the suction or out-stroke of the piston. The valve is kept tight up to its face by a spring, weight, or other suitable means, and is of sufficient size to always cover the ports of the oil channel.

6,342. Steam Motors. F. Lamplough, Glen Ridge, New Jersey, U.S. March 10th, 1897.

This invention relates to an improved motor system, consisting in the combination of a hermetically closed primary generator, a secondary generator into which water is pumped from the hot well; a feed-pump; a feed-water heater; a motor consisting of a pair of engines in which each engine controls its own lap and lead by a lever attached to its own cross-head, and controls the opposite engine's cut-off and reversing quadrant; a pressure-regulating valve which acts to divert the feed-water to the hot well when there is sufficient pressure in the secondary generator; a cylinder to contain compressed gas; a reducing valve connected to said cylinder; a gas-pressure regulating receiver; gas and oil supply regulating valves controlled by steam to regulate the supply of gas and oil to the burners in accordance with the steam pressure; a self-regulating oil burner and an air surface condenser provided with an air relief valve.

The construction of the generators consists of the combination of tubes provided with conical surfaces around their ends, end plates provided with conical surfaces fitting the conical surfaces of the tubes, passages in the end plates forming inter-communication between the members of the primary generator, between the latter and the steam spaces and between the steam spaces, said tubes and plates being bolted together by bolts having conical heads and nuts fitting corresponding conical holes in the end plates, and a tubular coil within each of such steam spaces.

It also relates to a condenser consisting in the combination of a number of hollow discs formed of corrugated plates connected together in pairs to form alternate steam spaces and air spaces, perforated connecting rings communicating with said steam spaces and with each other, bolts and a hollow central shaft for securing all the parts firmly together, an inlet, an outlet, and an air relief valve.

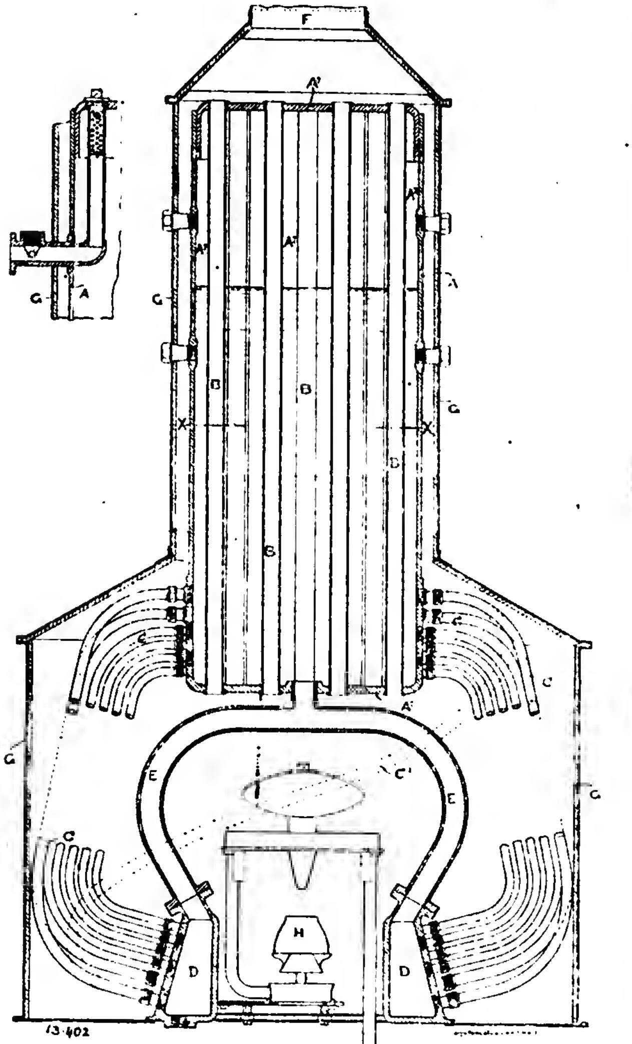
Also in the combination with the feed-pump of a valve operated by the steam pressure to regulate the supply of water to the secondary generator, and to divert it to the hot well when not required.

13,667. Acetylene Gas Plant. D. Whalley, 118, New Bank Road, Blackburn, Lancaster; J. Hacking, 53, Granville Road, Blackburn; and The Ideal Gas Company (Limited), 3, Taoketts Street, Blackburn. June 3rd, 1897.

A water cistern or tank is employed, connected by pipe and tap or valve with the gas generator, which may be of the form illustrated and described in Letters Patent No. 15,654 of 1896. The water supply tank is placed at such a height above the generator that there is sufficient pressure to allow of the latter being completely flooded before recharging, so as to ensure all gas being expelled therefrom. The generator is by single or double curved pipe connected with a condenser and cooler, consisting of a worm inside a vessel or tank of water, and the condenser or cooler is by a like pipe connected with an ordinary gasometer. Each of the single or double curved connecting pipes is carried to a point somewhat higher than the level of the water in the vessels to which they are connected, so that to whatever point the water in the vessels may rise it cannot rise as high as the bend of the single or double curved pipe, and so neither water nor water of condensation is able to get forward to the next vessel. At the lower part of each single or double curved pipe is a tap or valve, by means of which any water therein can be drawn off.

13,402. Tubulous Steam Boilers. R. R. Symon, 20, Abchurch Lane, London, and H. A. House, Junior, The Columbine Ship Yard, East Cowes, Isle of Wight. May 31st, 1897.

Relates to improvements in steam boilers of the kind known as tubulous—that is to say, boilers which consist of a series of tubes connected at their lower ends with a water chamber, and at their



13.402

upper ends with a steam and water chamber, the water to be evaporated being contained partly in the said water chamber, partly in the tubes, and partly in the steam and water chamber.

The object is to so construct the steam and water chamber that it shall afford a considerable amount of heating surface available for the production of steam, and incidentally for drying or superheating the whole of the steam produced in the boiler.

The figure represents a vertical section of a boiler constructed in accordance with the invention, and adapted to be heated with the vapour of liquid fuel, such as petroleum.

The steam and water chamber, A, is made of a vertical cylindrical or other suitable shape, with a tube plate, A^1, at top and bottom, and fixed in these tube plates is a number of vertical tubes, B, so that the entire steam and water chamber, A, forms a multitubular boiler.

The upper ends of the water tube, C, are secured in the sides of the steam and water chamber, A, and their lower ends in a water chamber, D, as usual. Preferably, several rows of these water tubes are employed, those which are situated lowest acting as steam generators, in which the water circulates upwards from the water chamber, D, at the bottom of the boiler to the steam and water chamber, A, at the top, and those which are situated highest acting as down-comers, in which the circulation of the water is downwards from the steam and water chamber, A, into the water chamber, D.

In some cases the water tubes above described as acting as down comers do not act sufficiently well as such. In that case we employ additional down-comer pipes from the steam and water chamber, A, to the water chamber, D, such as those marked E.

The furnace is formed, so far as its sides are concerned, by the aforesaid water tubes, C, much in the usual well-known way; but its top is formed by the lower tube plate, A^1, of the steam and water chamber, A, and the hot products of combustion pass partly in a lateral direction between the water tubes, C, and thence to the chimney, F, round the outside of the steam and water chamber, A, and partly through the fire tubes, B, which traverse the steam and water chamber, producing a certain amount of steam in the latter; and as the upper parts of such fire tubes, B, pass through the steam space, A^2, the steam in such steam space is dried or superheated to a certain extent by the heat of such products of combustion as they pass through the tubes to the chimney.

The water tubes, C, are intended to be of a helical form, as shown by the helical line, C^1; but they may be straight, or of any other shape that may be found suitable or convenient, according to circumstances.

The boiler is enclosed in a suitable casing, G, as usual.

H represents a vapour burner for burning the vapour of petroleum or other suitable liquid fuel of the kind described in the Specifications of Patents dated September 7th, 1893, and June 2nd, 1894, and numbered respectively 16,864 and 10,702, and dated January 20th, 1896, No. 1,414.

A modification is described for the combustion of solid fuel, such as coke.

Automobilism and Street Noises.—No class of people suffer from and abominate street noises more than those engaged upon literary work, and hence we, for our part, cordially support the objects of the Society for the Suppression of Street Nuisances. When, however, the secretary, presumably writing upon instructions from the Society, goes out of his way to write to the Press such nonsense as the following, then he is doing, no doubt unintentionally, his level best to perpetuate the very nuisances that his Society is formed to suppress. Says this gentleman, in a letter to the *Westminster Gazette*, referring to the Steam Omnibus Company:—"If we submit to steam buses, it means the thin end of the wedge. I take it we are reconciled to the cable-car, the motor-car (private and public), and electrical traction generally, but steam buses? What next? Has the world gone mad? I thought we had sufficient dangers and nuisances in our streets already without steam-engines coming to blow their shrieking whistles to order pedestrians out of the way. As it is, steam rollers, which proceed at a snail's gallop with a danger-flagged man ahead, frequently frighten horses and cause them to bolt. What will steam buses do, then? It is not in the least likely that private people will altogether give up horses in a hurry—even to oblige a private exploiting company—but if this outrageous project is carried out, it means that they have got to clear out of the way of street steam-engines, and that pedestrians, young and aged, will have to run for their lives between steam-engines, runaway horses, bicycles, fire-engines, Pickford's vans, tramcars, and numerous other (and people) killing vehicles." This effusion is ridiculous enough in all conscience; it has evidently not occurred to the writer that a motor-vehicle is infinitely less noisy than a horse-drawn one, and, let us add, infinitely less dangerous. We may inform this gentleman, and others who share his opinions, that the increasing use of motor-vehicles is being eagerly looked forward to by municipal authorities as the only means of diminishing the present awful noise of street traffic. In fact, in some districts, especially in Paris, it is a positive complaint that motor-vehicles are so silent that they give no notice of their approach; owing, however, to the great control that a driver, if he be intelligent enough, can exercise over his vehicle, it is very rare that accidents occur.

THE MOTO-VEHICLE EXHIBITION AT THE AGRICULTURAL HALL.

UNDER the auspices of Messrs. Cordingley and Co., the proprietors of *Industries* and *Laundry News*, the Sixth Annual Exhibition of Laundry Machinery was held at the Agricultural Hall, Islington, London, from the 29th ult. to the 3rd inst. In the last two years moto-vehicles have formed a feature of the Exhibition. The *raison d'être* of the association of these two very distinct branches of applied mechanics is by no means apparent either to the professed engineer or to the casual visitor; in fact, the association constitutes an anomaly, but then this remark applies to so many human efforts that it would be ungracious to condemn the Exhibition because it does not comply with the law of the eternal fitness of things. If, however, the projectors of this Exhibition are going to continue to hold exhibitions of moto-vehicles, we would suggest the propriety of entirely dissociating them from any purely trade display such as the so-called Laundry Exhibition, because from the public point of view there is nothing in common between the automobilist and the laundry worker. The public cares not who "takes in washing," but the establishment of lines of moto-vehicles carrying passengers and produce is a matter of the highest municipal and social importance. The dobbie-wallah on the banks of the Hûgli alike with the haughty "clear-starcher" in London or Paris can follow their callings with no legal restrictions or liability, but before one can drive a cab in these cities a legal permit is necessary; and in Paris, before one can act as a *chauffeur*, one has to pass an examination little if at all inferior to that required by our Board of Trade for the chief engineer of a mail steamer, while the law relating to carriers and drivers in this country constitutes in itself a respectable library. Remembering these things, we then utterly fail to see how it is possible that any good can result to the cause of automobilism by the association indicated. Moreover, we are by no means satisfied that the time is at all opportune for exhibitions of moto-vehicles. It is not two years since the Locomotives on Highways Act was passed, and hence much progress is not to be expected.

As a mere trade display of vehicles the show at the Agricultural Hall was no doubt a success, but it was not an exhibition, as we understand that word. It was singularly deficient in the first essential of an exhibition, in that it was lamentably lacking in instructional and educational value. Our point will perhaps be better elucidated if we refer to the other part of the Exhibition, viz., the laundry section. This was—and we cordially congratulate the participants therein—a pronounced success. It was, however, a purely trade display. Manufacturers of mechanical appliances used in the levigation of textile materials met those worthy and indispensable workers engaged in that industry on common ground, to their, no doubt, mutual advantage. Similarly the so-called moto-vehicle exhibition was only of interest to the experienced automobilist who knows sufficient, or thinks he does, to make himself indifferent to details, whereas a proper moto-vehicle exhibition should be replete with details, so that the "man in the street"—who, after all, is the person to study—can profit thereby. In this so-called Exhibition there was much to be seen in the shape of carriage building and carriage furnishing, but little motor mechanism.

To enclose a motor in the bowels of a gaudily painted and varnished vehicle, and call the whole a moto-car (to employ the vulgar name) appeals after all to but a very limited section of the public. What the public want to see is the internal mechanism—to see the motor in operation, and how the various manœuvres of starting, stopping, or steering are effected. It is not sufficient in these days of dawning education to tell a person to pull a lever this way and something occurs. He wants to know why the lever is pulled that way, and he wants to see how it is worked. One can see plenty of handsome vehicles in any large city without going to the Agricultural Hall, but the Exhibition at that place was, after all, little more than a collection of gorgeous vehicles containing hidden mechanism—as a rule jealously guarded from inquisitive eyes. We think constructors would in future exhibitions do well to pay more attention to the engineering than to the carriage-building part of their

FIG. 1.—AUTOMOBILE ASSOCIATION STAND AT THE AGRICULTURAL HALL.

exhibits. A moto-vehicle in frame, blocked up with the mechanism in motion, and an intelligent mechanic in charge would have been a technic lesson of the greatest value—the public, or rather some of them, would, perhaps for the first time, have realised how these vehicles are propelled and managed. No English firm had any such exhibit, but the Automobile Association of Paris and London showed the frame of a vehicle with the motor and mechanism exposed to view. As regards the motors, no steam motors were shown, and the spirit (petrol) and electrical motors were all carefully concealed within the vehicles. In our opinion sectional models, such as Messrs. Tangye, the well-known engineers, exhibit freely in their show room window in Queen Victoria Street, have an enormous

FIG. 2.—THE LATEST RIKER ELECTRIC CARRIAGE.

educational value and should certainly form part of any mechanical exhibition. Yet parts and models of motors showing the method of carburation, ignition, &c., in the case of internal explosion motors; and the various methods of winding, insulation, commutation, &c., in the case of electrical motors would not only have done much to make the Exhibition interesting, but would have done more to promote an intelligent knowledge of automobilism. Yet there were no such things to be seen. We looked in vain, too, for models illustrating road construction, a matter not less important than mechanism; there was not even a granite sett, nor a block of pine or Jarrah in the place. As regards processes illustrating wheel manufacture, both in metal and wood, and for all kinds of vehicles, tyre making and setting, axle setting, testing materiel—nothing relating to these matters was exhibited. The Exhibition was, in short, little more than a display of finished vehicles such as might be seen in Long Acre, and as such it had little interest for engineers interested in automobilism. For the reasons above stated it was deficient in educational value. We asked an apparent office boy in charge of some batteries what was the capacity of a certain cell. He replied he "didn't know, but it looked as though it 'eld about a pint." We gravely intimated that we referred to watt-hours. "Wot's them?" he said.

It will be gathered that we do not approve of such exhibitions of the character indicated by that at the Agricultural Hall, because they do not instruct the public and hence cannot benefit the industry of automobilism. As regards the late Exhibition it was, however, a great improvement on the preceding one. The exhibits were more numerous, there being nearly 100 vehicles this year as against 12 or so of last year, but it was not sufficiently representative; and it was remarkable that not one of the competitors at the late Liverpool Trials exhibited. Before, in fine, a really representative exhibition of moto-vehicles can be held at the Agricultural Hall or elsewhere, a radically different system must be adopted. In concluding these remarks we must express our dissatisfaction with the catering arrangements at the Agricultural Hall; they are bad even for London, and that is saying a good deal. The system that is in vogue in London show places of charging for admission and then giving the visitor the option of either having very expensive and usually very inferior refreshments from one firm or else going without any at all is inherently bad and ought to be stopped forthwith.

As regards most of the exhibits the mechanisms relating to them have been for the most part described at various times in the columns of The Automotor. The largest and the most important, and at the same time the most novel exhibit, was the group of divers vehicles shown by the Automobile Association, but of this we speak at length elsewhere.

*The Daimler Motor Company had six vehicles, all identical as regards mechanism, all having 5½ I.H.P. motors, but differing as regards their bodies. They included a jaunting car to seat six persons, two victorias, a coupé brougham, a convertible van lorry, a Rougemont wagonette to seat six, and a Wyley phaeton to seat four. Needless to say that in workmanship and finish these vehicles left nothing to be desired.

*The Hewetson Motor Company had five vehicles—four "Ideal" voiturettes and one dog-cart; all have motors and mechanism on the Benz system, which is well-known to our readers. All these vehicles look exceedingly compact and not at all inelegant. A novelty with them is a water cooler in the form of an open annular tube exposed to the wind.

Messrs. F. Jackson and Co., of Oxford Street, showed two De Dion quadricycles built to carry two persons. The motor is stated to be of about 1¾ H.P. There is nothing novel in the details. The same remark applies to the two cabs shown by the London Electrical Cab Company.

*The London Motor Van and Wagon Company had a parcels van and a phaeton, both fitted with Daimler motors. The workmanship of these vehicles is very good and substantial.

*The Motor Manufacturing Company, of Coventry, had a large and interesting exhibit, comprising dog-carts, phaetons, wagonettes, and a parcel van; all, however, bad Daimler motors of 5½ I.H.P. There were also Bollée voiturettes, moto-bicyclettes, and De Dion tricycles. The Bollée voiturettes have been much improved, and are fitted with powerful motors. One motor was said to indicate 4 H.P. Considering the difficulties of "indicating" these small motors and the divergent results often obtained, we think it would be more satisfactory to state the actual power given off at the peripheries of the driving wheels—this could easily be ascertained. The Company is introducing the Werner moto-bicyclette, of which we have been furnished with the following description:—"The motor is of the Werner type, having one vertical cylinder, using petrol (doubly refined benzoline). It has two fly-wheels, which are arranged one either side of the crank chamber. The induction valve is on the right hand side of the cylinder, and is automatic, being opened by the suction of the piston, and closed by the extension of a spring on its shaft. The exhaust valve is worked by a cam on a small intermediary shaft, which is geared on to the crankshaft, and opens every two revolutions. The lubrication of the cylinder is effected by the crank splashing oil out of the crank case. The charges are fired by means of an incandescent nickel tube, kept at a white heat by a Bunsen burner fed by petrol under pressure. The tank supplying the burner forms a mudguard round the front wheel. The supply tank for the motor is fastened on the top tube of the frame, at the end of which is the carburettor. The amount of spirit entering the carburettor is controlled by having a very small hole in the tank, which is otherwise perfectly closed, the air resistance preventing too great a supply from passing into the carburettor. The carburettor is cylindrical, and comprises two cylinders, one within the other. The inner cylinder is about ½ inch smaller in diameter and 1 inch shorter than the outer. The inner cylinder is constructed with an air-tight chamber at the bottom, the sides above which are perforated, the top being plain; round the perforated part of the cylinder is wrapped two or three layers of very coarse cloth, up which the petrol soaks by means of capillary attraction; this, of course, induces vaporisation, which, however, does not take place quickly enough to keep up a constant supply for the motor, and to increase the supply an air inlet is fitted through the outside cylinder, which causes a rush of air to pass through the perforations and out into the feed-pipe, which causes the vaporisation to take place with sufficient expedition. The amount of air thus admitted is insufficient to form the explosive mixture, so another air inlet is fixed on the handle-bar, which is controlled by a valve actuated by a small lever near the left handle, which enables the rider to admit the correct quantity of air or cut it off at will, and so change the speed of the machine. By moving this lever in the opposite direction it holds the exhaust valve open, thus releasing the compression, and enabling the rider to exert the necessary force on the pedals to start the motor. The design of the machine is identical with that of an ordinary safety bicycle. The motor is fastened on to the front of the machine, being bolted at the bottom to a plate protruding from the front forks, supported by stays brazed on to the fork blades, and held by a single stud at the top passing through a clip from the steering tube into the top of the cylinder. On the outside of the left fly-wheel is a small pulley with concave face; this is connected to the driving pulley built on the same axle as the front wheel; a leather band transmits the motive power to the cycle. The pedals are fitted as a means of starting the motor, and assisting it up steep gradients, also at the same time forming a rest for the feet, and, being on a ratchet, immediately the motor starts remain stationary. The weight of the motor is equally balanced, and so assists in steadying the steering of the machine. A powerful hand-brake is fitted to the hub of the rear wheel, and is applied by the ordinary lever on the handle-bar."

*M. Carl Oppermann showed his electric victoria, of which we understand a good many will shortly be seen in the London streets.

*The Prétot Motor Syndicate showed examples of their fore-carriage or *avant* train attachment. The great merit of this is that it is applicable to a very wide range of vehicles.

*The Riker Electric Motor Company, of New York, represented on this side by Messrs. Shippey Brothers, showed a remarkably neat and well-built four-wheeled vehicle, having seating accommodation for four persons, but designed mainly for the use of commercial travellers. Its weight without batteries is only 650 lbs., and it can be worked by any of the better known types of battery. The present vehicle is actuated by a battery consisting of 40 Headland cells, which is placed in the rear compartment of the vehicle immediately over the rear (driving) wheels. The motor, which is an enclosed series-wound one, is hung in a similar way as on the motors of electric tram and railroad cars, and which we have no hesitation in saying is the only proper method. The motor is enclosed in a strong metal casing so as to exclude dust, &c., and is carried at its yoke end by the driving axle through a sleeve. The armature end is supported by springs, &c., from a transverse bar joined to the side rods. At the

* Previously described in The Automotor.

armature end is the armature pinion gearing into the driving wheel on the axle; to this driving wheel is also attached the differential gear, the whole being thoroughly enclosed, and looking extremely neat. By having the motor, its gearing, and the battery nearly over the driving axle, the adhesiou is very great, a point of no small importance in these light and fast vehicles. The frame is made of steel tubing, well socketed and stayed. The steering is effected by a modification of the Ackermann gear, by which it is claimed that the correct alignmeut of tbe wheels is always ensured. We at any rate could not detect any imperfection in the apparatus. Tbe wheels are pneumatic tyred and attached to the hubs with tangent spokes. Tbe method of fitting these bubs is novel and ingenious. It consists of an inner and outer sleeve, the inner one being on the axle and separated from the outer one by a series of ball bearings. The fore wheels, of course, are pivoted, and rotate between two coned surfaces.

The latest type of Riker controller is used in this vehicle, and is constructed for four speeds forward and two backwards, and arranged for driving at three, six, nine, and 12 miles an hour. The manœuvring and braking mechanism is very well thought out and arranged, and enables tho driver to obtain almost any variation in the speed. The foot brake is operated from the floor of the vebicle and is connected to a band running over a brake pulley fixed on the motor shaft. Another point is that the batteries cannot be charged unless the controller lever is in a neutral position, which cuts out the motor.

All the Riker vehicles are fitted witb an automatic cut out, so all that is necessary is to plug the street mains or source of supply, and when the batteries are fully charged tbey are automatically cut off from the charging current without any attention whatever, as the batteries take care of themselves, and by this arrangement just sufficient current is stored without waste of power.

Each vehicle is fitted with a searchlight head lamp, also two side lamps of ornamental appearance. It is fitted with a foot bell gong, also with a dead beat combined volt and ampère meter, which is scaled for cbarging as well as discharging, and with an overload switch which is combined with tbe brake switch. This special switch cuts out the motor at 300 per cent. overload before the motor can be injured by the overload. There is also a locking-up switch, so that current cannot be used by any unauthorised person. This vehicle is remarkable for its excellence of construction and its accurate fitting and finisb.

Messrs. Shippey Brothers report to us that they had a very successful fortnight at the Exhibition, having sold the motor on show there to the Rev. F. S. Laurence, of Birmingham. They also booked orders for two other vehicles of this type, one Riker victoria, one draper's parcels van, and one traveller's trap as above described. We learn that a limited company is being privately formed to purchase the "Riker Patents," and to manufacture the various Riker carriages and motors and gearings in England.

*The Elieson Lamina Company showed an electric carriage and a light parcels van, both fitted with motors and batteries and chain gear of their well-known makes. The chain is specially noticeable, as it entirely obviates the use of differential gear, and gives excellent results in practice.

*The Headlands Storage Battery Company had two vehicles—a brougham and a two-seated phaeton. The former is well-known as a reliable and practical machine. As will be seen, their latest vehicle is most substantially constructed, and of not unpleasing appearance. In all externals it resembles a rather favourite type of carriage much used in the country. It is mounted much in the same way, but the wheels have rubber tyres. It has a seating capacity for four persons, and can also carry a quantity of luggage. Its tare weight is 23 cwt. The fore part is made with a hood, and tbere is a light splashboard. The starting, steering, and brake levers are placed close by the driver, who thus has full command over the vehicle. The interesting part of the vehicle is, of course, tbe motor mechanism. This consists of a 4 B.H.P. series-wound motor placed longitudinally, and its frame is pivoted at one end to the axle; hence any motion in the carrying springs does not affect the running. At the end of the armature spindle is a steel bevel pinion which gears into a bronze bevel wheel, the velocity ratio being 9 to 1. This bronze bevel wheel is mounted on the driving axle, and a differential gear is interposed. The arrangement is very good and compact, and should wear well. Current for tbe motor is derived from a battery of 40 Headland cells, which are carried in the body of the carriage or "boot." These cells are arranged in four groups of 10 each, and by a special switch can be arranged in four groups in parallel or series, or in two groups in parallel, each with two groups in series. No resistances are used, the various speeds being obtained by the different groupings. The capacity of the battery is 150 ampère hours, and a single charge suffices for a run of about 45 to 50 miles. The cbarging current is 30 to 40 ampères, and the normal discharge is at the rate of 25 ampères. It has three speeds, viz., 3, 7, and 15 miles per hour. As regards the phaeton, we were not so favourably impressed. This vehicle is constructed to carry two persons, and is intended to run about 40 miles over ordinary roads witb one charge. It is fitted with a 4 H.P. series-wound motor, mounted on the front axle and driving the front wheels. The battery consists of 40 cells of the Headland patent type, having a capacity of 140 ampère-bours. The regulation consists of three speeds, obtained by connecting up the battery on the parallel series system, no resistance being used. Tbe battery is contained in a box at the back of the carriage, and thus the total weight of motor, gearing, and battery is distributed over the four wheels. The carriage is finished in the best style, aud is fitted with three brakes, namely, a band brake, a side brake, and an electrical brake; any one of these being capable of stopping the vehicle in a few yards. It is claimed to be an advantage to have the motor on the front axle. The early railway engineers entertained the same idea. Automobilists can learn a good deal from locomotive engines of to-day, and it will be noticed that in modern engines the drivers are placed as far as possible in the rear of the vehicle, aud as much of the available weight as possible is placed on them.

Fig. 3.—Headland Electric Brougham.

Fig. 4.—Headland Two-seated Phaeton.

* Previously described in The Automotor.

Mr. F. Simms, C.E., of Norfolk Street, Strand, exhibits an ingenious magnetic ignition apparatus which gives a very thick spark, and we should think renders a miss-fire an impossibility. We illustrate this in the accompanying drawing. Mr. Simms has furnished us with a full description, of which the following is an excerpt:—

"This electro-magnetic machine weighs about 7 lbs. for cycle motors and 18 lbs. for automobiles running at not less than 300 revs. per minute, and 28 lbs. for stationary gas and oil engines running at not less than 60 revs. per minute. An advantage is that a sufficient spark for ignition can be obtained at a comparatively low speed, although, as is the case with all such machines, the higher the speed within limits the better the spark.

"For cycle motors a very efficient machine has been produced, which does not exceed the gross weight of 8 lbs.

"As an addition to the alternating magneto-electric machine a timing device has been devised, which makes it possible to time the

"It will be obvious from this that, supposing the half-speed shaft to be stationary, as the Sleeve 2 is drawn forward its position varies relatively with that of the half-speed shaft in proportion to the amonnt it is moved, and the half-speed sha't being in constant position with the crank shaft the sleeve varies in this proportion with the crank shaft. Supposing, then, that the archimedean thread is of sufficient length to make one complete turn round the circumference of Sleeve 2, it will also be obvious that any one point in its circumference can be moved throughout the whole of the cycle.

"Referring back to Sleeve 1, on which Sleeve 2 slides, attached rigidly to it, or made in one piece with it, is a cam made in such a manner as to raise gradually the cam rod and suddenly allowing it to drop. On the same cam is fixed a small crank pin fitting into a solid block on an arm keyed on the spindle of the alternating magnets.

"It has been shown above that the Sleeve 2 can be moved readily to any point in the cycle, and the cam and the crank pin, rigidly

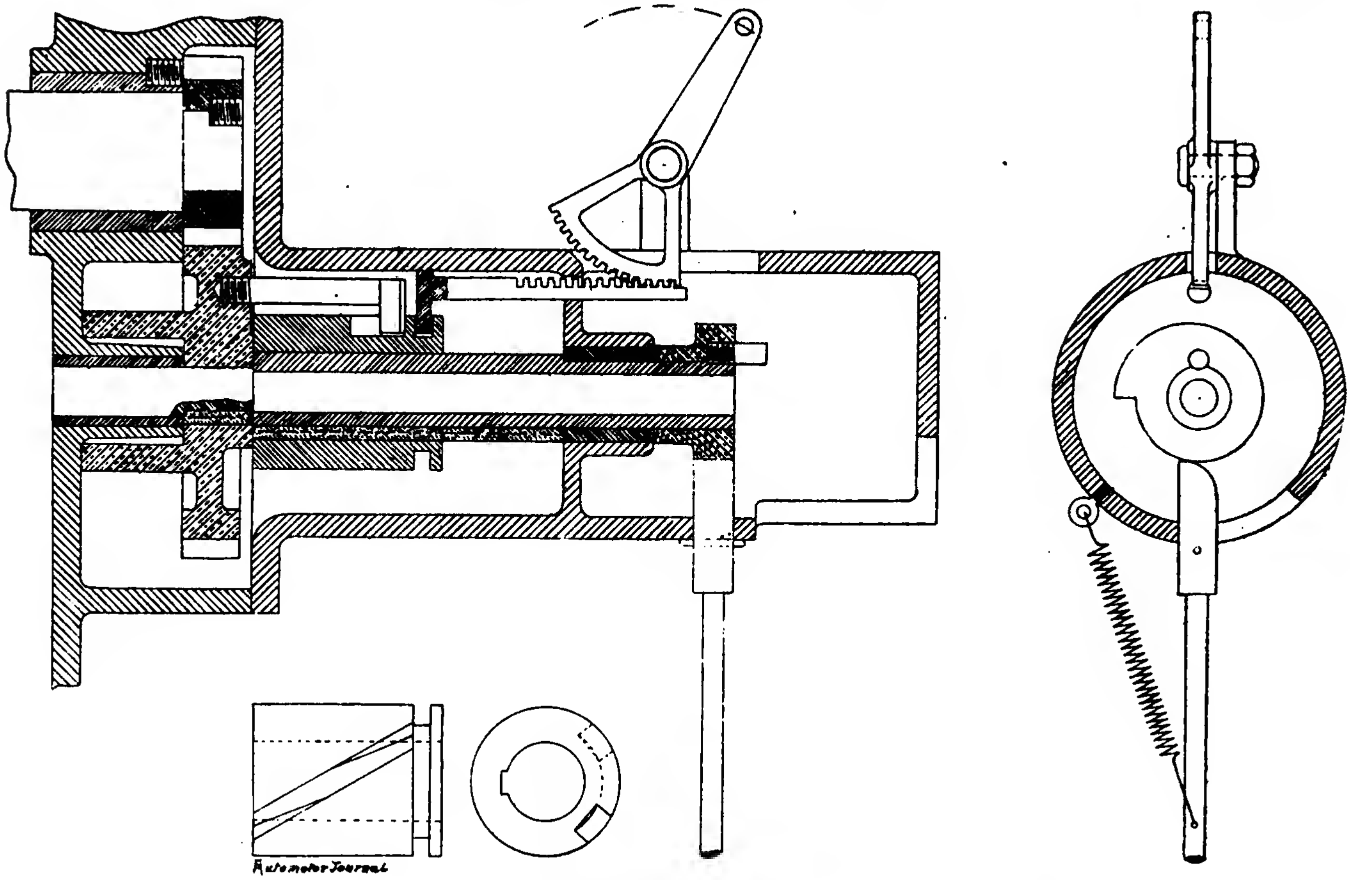

Fig. 5.—The Simms Magneto Igniter.

spark at any particular point in the stroke of the motor. The usual method adopted for applying this apparatus to small motors of automobile vehicles is as follows:—In a single-cylinder motor it is usual to enlist the services of the half-speed shaft carrying the exhaust cam; on this is fitted a loose sleeve (1) running throughout the whole length. Keyed to the Sleeve 1 is a second bush or sleeve, which we will call Sleeve 2, which, though rigidly fixed circumferentially to Sleeve 1, is enabled to slide thereon. There are two grooves in Sleeve 2, one of which forms an archimedean thread, from which the timing gear takes its name, the other running circumferentially round. These take two arms or lugs, one of which is attached permanently to the gear wheel or half-speed shaft itself, the other end of the same fitting in the groove forming the archimedean thread.

"The other arm is fitted to form the rack gearing with the quadrant moved by hand from any convenient position. When this quadrant is moved the arm is drawn backward or forward, as the case may be, and moves with it the Sleeve 2.

attached to the Sleeve 2, must necessarily move with it. As the crank revolves and works the half-speed shaft, this cam in revolving raises or revolves a rod which, by means of levers, taps the contact-breaker at the exact moment when the spark is required. This contact-breaker is constructed as follows:—A cast-iron plug is screwed or fitted so as to leave an open passage from the combustion chamber. Through the plug run two pins, one fixed and insulated, and connected directly by an insulated wire to the magnets, and the other constructed so as to revolve therein, having at either end a bell crank, the outer end being held in position by a light spring, and attached by means of levers carried on the revolving rod, and the inner end resting on the insulated pin.

"At the moment when the tension in the alternating magnets is greatest, the cam suddenly releases the rod, strikes the bell crank, and separates the point of contact between the insulated pin and the inner bell crank, thereby causing a spark.

"It will be obvious to all those acquainted with explosion engines that a variation in the timing of the explosion of the gas means a variation in the speed of the engine. More than that, however, can be accomplished by this device, for when a motor fitted to a vehicle is standing idle for a few minutes, the spark may be timed to take place during the suction stroke, thereby decreasing the speed to a minimum. Such reduction in the speed will be much appreciated under certain circumstances."

We may remark that in principle the method employed is the production of an alternating current of high E.M.F. by the rapid reciprocation of a wire wound bobbin between the poles of a set of permanent steel horseshoe magnets on what is in effect an open circuit, the ends of which are, of course, led into the cylinder ends. The method is really that used in magnet exploders and in some early forms of submarine mines of which we have had experience. By using a superior steel a permeability of 8,000 to 10,000 "lines" per square centimetre might be obtained leading to a considerable reduction in the weight of the magnets. At the same time this method of ignition is unquestionably the correct one to employ, and if Mr. Simms will slightly modify his design he will find a large demand for his igniter. Batteries are really the most unsatisfactory things about these electric ignition devices, and anything that will obviate their necessity is to be welcomed.

The Southern Motor Car Company, which represents the Georges Richard Company, of Paris, show the Richard Benz phaeton which we recently described, and a few second-hand vehicles. In addition they had a good stock of motor fittings on view.

Turning now to the Continental exhibits, as before stated those shown under the auspices of the Automobile Association will be dealt with separately.

MM. Daniel Augé et Cie. showed a petroleum motor termed the "Cyclope." This is one of that large number of petrol motors all of which work on the Beau de Rochas cycle, all of which are unidirection, and all of which are run at very high speed. They are differentiated from each other by the fact that some are vertical and others are horizontal, and also by their various carburation and ignition devices, all of which are essentially one in principle. The Cyclope motor is a two-cylinder horizontal one, and, as will be readily understood, an impulse on the shaft is imparted once every revolution. The principal feature about it is that the speed regulation is effected by varying the relative quantities of petrol and air admitted to the carburator, and it is claimed that the speed by this means can be varied from 300 to 1,200 revs. per minute. The normal speed is 600 revs. per minute, when 6 H.P. is said to be developed. We have not, however, seen any official tests of this motor.

Le Carbone Levallois Perret Compagnie, of Paris, had an interesting exhibit of ignition cells, induction coils, carbon brushes, &c.

The Fulmen Accumulator Company had a most interesting exhibit, consisting of their cells and accessories, now so well known since the late Paris cab trials, and of which full accounts of their capacity, &c., have appeared in THE AUTOMOTOR. To again describe them would be superfluous. This Company also had on view that type of cell they manufacture for railway work, and in addition several of the vehicles that took part in the recent Paris cab trials. These were much admired for their graceful lines and elegant appearance, although the Jeanteaud hansom, with the motor perched in front, came in for considerable criticism. We observe that a contemporary which discusses the amateur side of automobilism, waxes merry over the coiled rope brake fitted to the Jeanteaud cabs, and so universally employed on the Continent. Of course this is quite pardonable, and we make no complaint. In order, however, that no incorrect impression may obtain it may be as well to point out that the coiled rope brake, such as is used in the Paris omnibuses, is one of the most efficient mechanical brakes we have. It may not be generally known that a modification of it was exclusively used on railways till the vacuum and other pressure brakes superseded it. Still another modification of this coiled rope brake is the basis of the well-known Lindsay coil clutch. We strongly recommend the coiled rope brake for all moto-vehicles, as it is simple—a child can use it with as much effect as a strong man. It is cheap and easy to repair or replace.

As a finale to the Exhibition, Mr. Cordingley arranged a pleasant little outing on Sunday, the 4th instant, to Whitton Park Club, Hounslow. In consequence of some ridiculous paragraphs which appeared in the daily Press stating that some hundred motor-cars would take part in this run, and announcing the start from the Agricultural Hall at 2.30 on the Sunday, a big crowd was brought together, practically along the whole of the route, to see this wonderful procession, including "the specimens with very quaint devices." We do not know how this information was disseminated, but considering that only about 11 vehicles went to Whitton Park from Islington, we think the "inspired" source should be given. Amongst those vehicles which did start were a Mors carriage with six seats, driven by the Hon. C. S. Rolls; a Le Blon four-seated car, driven by Dr. Lehwiss; the electric Jeanteaud cab, driven by M. Jeanteaud; three Daimler carriages, one of which was driven by Mr. Hodges, of the London Motor-Van and Wagon Company, another being the property of the Motor Manufacturing Company; a Vallée racing car, driven by Mr. Frentzel; one of the Motor Manufacturing Company's "Werner" bicycles; two electric cabs, and a De Dion tricycle. The Mors carriage accomplished the journey from the Agricultural Hall to Whitton Park within a few minutes of the hour. Quite a number of guests sat down to dinner in the Club House, the return journey being made at about 9 o'clock.

FIG. 1.—8 H.P. HERCULES (Berret System).

THE AUTOMOBILE ASSOCIATION (LIMITED).

THIS is a company which has been established in England for the purpose of supplying every make of moto-vehicles, including all the best English types, and more especially the better class of French-built vehicles to those who, recognising the larger experience in automobile construction that has been obtained on the other side of the Channel, prefer Continental-built vehicles to those of home manufacture, and it must be admitted that, save in heavy moto-vehicle design, our French rivals are in many respects ahead of us. Even that motor most generally employed in Great Britain for vehicle propulsion is a Continental design. Of course the explanation is that this branch of mechanical engineering has not been in existence in this country for more than two years, and hence it is only to be expected that we should be somewhat behindhand. The Automobile Association is the agent in this country for many of the better known French and German firms engaged in moto-vehicle construction; and at their principal depôt in Holland Park Avenue they have a perfect exhibition of vehicles of all kinds suitable for light traffic. We recently inspected their collection and proceed to describe the more important of them.

The Hercules (Berret system) (*see* Figs. 1-5) is a comfortable and substantial moto-vehicle having seating accommodation for four persons and room for a reasonable quantity of luggage. It is specially intended for service in hilly country districts and is designed to climb gradients on fairly good roads of 12 to 13 per cent., fully laden, at a speed of 6 to 7 miles per hour; while on the flat the speed varies from 20 to 25 miles per hour, according to the state of the roads. The framing is of steel and the body of the vehicle is connected to it by ordinary plate springs. The axles are of mild

FIG. 2.—8 H.P. HERCULES—("Spider").

steel, the front one having jaws for the pivoted axles of the steering wheels. The wheels themselves are of wood, the spokes fitting into metal sockets riveted to the inner rim; outside of this are solid rubber or pneumatic tyres. The steering gear consists of a cross-bar mounted on a vertical spindle which by means of chain gearing attached to arms on the pivoted axles simultaneously turns these latter.

The motor, which is of 8 I.H.P., is placed on the framing and has no connection with the body of the car excepting through the springs, hence the vibrations imparted when it is running light are scarcely felt. It consists of two horizontal cylinders placed side by side and working on the usual Beau de Rochas cycle, with electric ignition. The carburator is of the self-feeding gravity type, and is practically automatic in its action, but the quantities of petrol and air admitted can be varied at will; thus the richness of the mixture and hence the speed can be regulated from 200 to 800 revs. per minute. A small circulating pump is attached to the motor and which cools the cylinder; the temperature of the water is kept low by forcing it through a series of coiled tubes placed in the upper part of the motor chamber and freely exposed to the air. The power transmission gear will be understood by a reference to Figs. 3 and 4. On the motor shaft are three pulleys for forward motion, g, g, g, and two fly wheels, g^1, g^1, the former gear, by means of leather belts, with corresponding pulleys, k, k, k, on an intermediate shaft, upon which are mounted the differential gear, j, and at the extremities, pinions, which by means of chain transmit the motion to the rear driving wheels. The leather belts for transmitting the motion are made a very slack fit, any particular one is put in gear by means of a jockey pulley, worked by a lever. Three brakes are fitted; two are of the coiled rope type working on the hubs of the drivers, and one working on the differential pulley. The petrol supply is carried in a tank underneath the front seat, while the water is carried in a tank under the rear end of the vehicle.

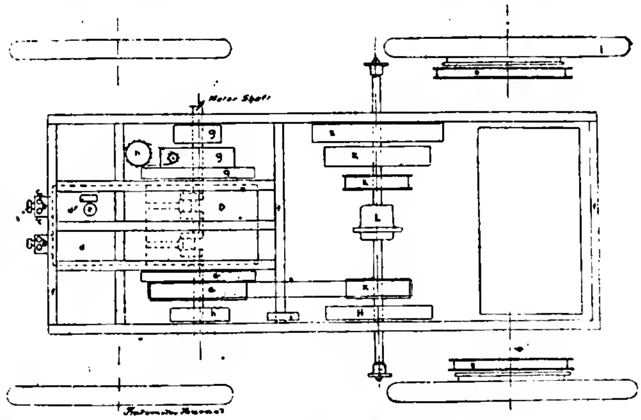

FIG. 3.—8 H.P. HERCULES (Plan).

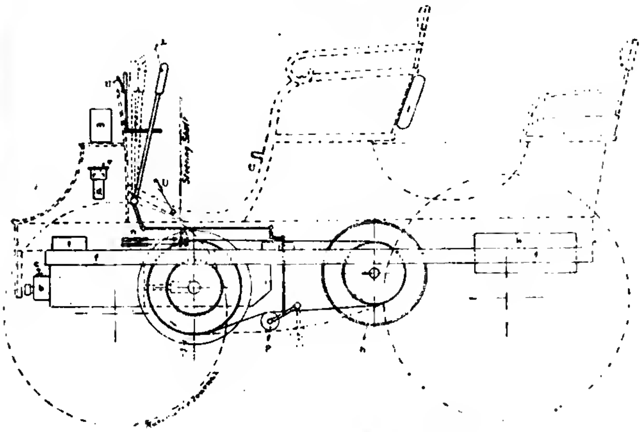

FIG. 4.—8 H.P. HERCULES (Side Elevation).

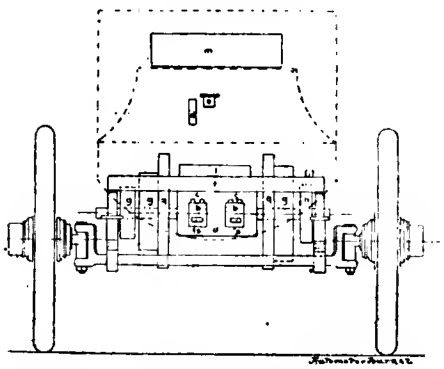

FIG. 5.—8 H.P. HERCULES (Front Elevation).

The Vallée racing moto-vehicle, shown in the accompanying drawing (Fig. 6), has made the extraordinary speed of 42 miles per hour on ordinary roads, thus showing what a well-built moto-vehicle can accomplish. Needless to say this speed was not attained in England. As will be seen, the construction of this vehicle proceeds largely on bicycle lines; the framework being of

Fig. 11.—Lynx Two-Seated "Duc" (Le Blon System).

steel tube, well braced together, while the wheels tangent spoked and pneumatic tyred, and, of course, run on ball bearings. Aluminium is largely employed in this vehicle with the object of reducing weight, and most of those parts not exposed to stress are of this metal. The seating capacity is limited to two persons, and their luggage is carried in the box casing behind the seat. Notwithstanding the small weight to be moved a 6 I.H.P. spirit motor is fitted. This is of the horizontal two-cylinder type, with cranks at 180° apart. The distinguishing feature of the motor is the very long stroke; this is no less than 15 inches. Of course, this greatly conduces to smoothness of running and permits of a comparatively low speed of revolution—always a desirable feature. The ignition is electrical, the cells being carried in a casing on the front platform. The water for cooling the cylinders is kept at a low or comparatively low temperature by circulating it through a long convoluted pipe fitted with radiating gills of aluminium. This pipe is placed in front of the vehicle just where the splash-board is usually, and so receives the full refrigerative benefit of the air. This pipe holds about six gallons of water and this quantity suffices to keep the cylinders sufficiently cool even on prolonged runs. Leather belting for the power transmission and speed regulation is used, and the general scheme will be gathered from the accompanying plan (Fig. 7), from which it will be

Fig. 13.—Lynx Parcel Van.

seen that the motor shaft drives an intermediate shaft at various speeds according to the gear employed, while the intermediate shaft transmits motion to the driving wheels through chain gearing, the differential gear being on the intermediate shaft. In this racing moto-vehicle there are but two speeds, but in the others three speeds are provided. The steering mechanism and the stopping and speed variation gear are of the ordinary type and call for no special remark. This vehicle is distinguished for simplicity and power, while the workmanship is very good.

Figs. 8, 9, and 10 show other designs of moto-vehicles on the Vallée system. The six-seated phaeton, or voiturette famille (*see* Fig. 8), is especially noticeable as being eminently suited for country use, for excursions, picnics, and the like. It is, so far as the mechanism is concerned, similar to the previous vehicle, and like it is fitted with bicycle wheels. The construction is, however, more substantial, and comfort rather than speed has been the point aimed at. It will be noticed a light aluminium roof with side curtains is fitted, thus making travelling in such a vehicle a distinct luxury.

Fig. 14.—The Longuemare Carburettor.

The "Lynx" (Le Blon system) moto-vehicles are shown in Figs. 11, 12, and 13. As will be seen, they include most of the usual types of light vehicle, and, so far as the bodies are concerned, do not differ greatly from other makes. In the mechanism, however, are some few important departures. The motor is of the two-cylinder inclined type, the power developed being about 4 H.P.

2 Q

The ignition is electrical and the combustion effected by the Longuemarre carburettor.

The power is transmitted by leather belts to pulleys on an intermediate shaft, and from thence to the driving wheels by chains in the usual way.

The carburettor (*see* Fig. 14) consists of a supply tank, a mixture regulating valve, and the carburettor proper. The supply tank is seen at Z; this consists of a chamber with a ball float, which actuates a needle valve. Spirit is supplied from another tank situated above this tank, and hence always tends to flow into the chamber and any falling of the ball float admits the spirit while its rising closes the cock; this occurs when the spirit is as high as shown by the line Y. From this chamber the spirit flows by gravity into the bottom of the carburettor and, of course, rises till it reaches the same level as in Z. It now flows outwards into W, but is here met by a current of air which causes rapid evaporation and the production of a saturated mixture of air and spirit vapour and, of course, highly explosive. The mixture passes through a series of gauze meshes, so as to intimately mix the particles, and through the valve to the pipe U. Of course the quantity of mixture can be regulated by the position of this valve. From U the mixture passes to the ignition valve and is burnt with explosion in the ordinary way. An advantage possessed by this carburettor is that it enables a motor to be worked either by ordinary coal gas or petrol.

The Barriere moto-tricycle is represented in the accompanying drawing (Fig. 15). This type of moto-vehicle bids fair to become very popular on both sides of the Channel, as it is light, very fast, easily managed, and by no means expensive. In its mechanical features it differs considerably from other moto-tricycles. In the first place the construction is such that it can readily be converted into a voiturette or motette with seats for two persons; for this purpose it is made exceptionally strong. The motor is of $1\frac{4}{5}$ H.P., running at 1,200 revs. per minute. It is enclosed in an aluminium casing, in which are also two fly-wheels. The ignition is electrical and is effected by a cam movement from the valve shaft. The spirit tank is also the carburator, and a change of power is effected by varying the relative quantities of spirit vapour and air on the mixture; this, of course, allows very great variation in the speed. All the valves, &c., are actuated by rods, and handles placed conveniently to the driver's hand, and a powerful brake gear is provided. The wheels are made of extra strength to withstand the wear occasioned by the high speed that is attained; this frequently reaches over 30 miles per hour on good roads.

The Cambier Moto-Vehicles.—Among those manufacturers who have established a reputation for substantial, comfortable moto-vehicles, MM. Cambier et Cie., of Lille, deserve special mention. The general type of their vehicle will be gathered from the accompanying illustration (Fig. 16). These vehicles are designed, not so much for speed, as for continuous running. They are distinguished as being very comfortable and well adapted for rough country roads. In the illustration, which represents a "Duc," it will be noticed that the body is hung rather low. The framing is tubular and is connected to the body by plate springs in the usual manner. The fore wheels are carried on pivoted axles. The wheels are of very substantial make and have heavy pneumatic Mechelin tyres. The motor is a 4 H.P. Benz, the transmission and speed gearing being on that well-known system. The power is delivered from the intermediate shaft to the rear wheels, the drivers, by sprocket chains. The steering gear, speed gears, &c., are all placed conveniently to the driver. In point of comfort and reliability in running these vehicles leave little to be desired. We may mention that the success of MM. Cambier et Cie. is to be attributed to the fact that long before the era of the moto-vehicle they were well established as engineers. Since the advent of the automobile they have laid down a large plant, consisting of the latest American machinery, for turning out moto-vehicles of all kinds. More recently they have brought out three types of motor, viz., 6, 8, and 12 H.P. with spur wheel transmission instead of belting, together with a noiseless speed changing device. We may mention that MM. Cambier et Cie. are the contractors for the famous diligence mail service in Algeria, which is carried on entirely by moto-vehicles of their make. They also manufacture fire automobiles and find these are much appreciated by French municipal authorities. We understand that MM. Cambier et Cie. are contemplating the establishment of a branch house in England, with which object a limited liability company will be formed shortly.

The Mors moto-vehicles (*see* Figs. 17 and 18), although resembling in outward appearance the generality of French vehicles is yet distinguished from them by a special type of motor. This consists of four cylinders inclined in pairs at an angle of 45 degrees, the pistons working on a single crank. While one pair of pistons is compressing the gas mixture the other pair is performing its active stroke, so that the crank receives two thrusts at each revolution. By this arrangement the motor is able to run very steadily, and there is said to be an almost entire absence of vibration when the transmission mechanism is thrown out of gear. Above the crank is a distributing shaft geared down to half the speed by pinions, and this shaft carries cams for actuating the valves, which are enclosed in the upper part of the ribbed cylinders, and the electrical igniters. Each cylinder has an inlet valve opened by simple pressure; the exhaust valve is operated by a rod, one end of which presses on a cam on the distributing shaft. As the piston makes its downward stroke a volume of air, which has been carburated in a special apparatus, is drawn through the valve, and is compressed by the piston making its upward stroke, and then exploded by electricity. The piston is

Fig. 15.—Barriere Tricycle.

thus driven forward again, and at the moment of returning the cam on the distributor opens the exhaust valve and allows the piston to expel the burnt gases. The electricity is provided by a small dynamo driven by friction by the fly-wheel, and generating enough current to explode the mixture and keep the accumulator permanently charged. The accumulator is only employed for starting the vehicle. The current from the dynamo passes through an extra-current bobbin, and is conveyed inside each cylinder, where a "breaking-spark" is produced by means of a couple of pallets and an insulated rod, the pallets being operated by cams on the distributing shaft. This spark is certain and instantaneous in its action, and all danger of erratic explosions is said to be avoided.

The carburator is of a special type invented by M. Mors, and is intended to provide a perfectly regular supply of gas mixture for the engine, so as to prevent the dangers incidental to such appliances, where the supply of mixture is liable to be in excess of the needs. The spirit flows by a pipe into a receptacle in which there is a float. When the spirit reaches a certain level, the float rises and shuts a valve, thus cutting off further supplies until the level of the spirit in the receptacle again drops, when the valve is, of course, opened. From this receptacle the spirit flows up through a pipe into an atomiser in the shape of an inverted cone, and a quantity of air equal to that represented by the downward stroke of the piston enters through a pipe and mixes with the spirit. The quantity of air admitted and the density of the mixture may be regulated with the greatest nicety by means of screws.

The crank of the motor is geared on to the counter-shaft by bevel pinions, one of which serves for the forward movement, and the other for reversing. Leather belting transmits the power from the counter-shaft to the driving axle, and the speed is varied by moving the belting on to one or other of the pulleys. The mechanism is thrown out of gear by a pedal, and another acts on the brake with such force as to stop it almost instantly. The carriage complete weighs only 570 kilos, and, running at from 300 to 1,600 revs. a minute according to needs, the motor will, it is stated, give nearly 8 H.P. on the brake. The vehicle will attain speeds of 19 miles an hour on the level, and will climb gradients of 12 per cent. at 6·5 miles an hour. It is claimed that once the carriage is started it will run for 10 hours without its being necessary to renew supplies of water or petroleum, or to pay any attention to the machinery. The oiling is done automatically; in fact, the whole carriage has been designed to avoid the necessity of any attention being given to it once the engine is started. Fig. 18 represents the type usually seen, and Fig. 17 is the latest type, specially fitted with the new reversing gear in accordance with British legal requirements.

The Klaus moto-vehicles comprise voiturettes or three-wheeled vehicles and phaetons. The former is a development of the moto-tricycle, the framing and wheels being carried in the usual tricycle manner. The motor is a horizontal single-cylinder one of about 3 H.P.; it drives by leather belting an intermediate shaft which gears directly on to a spur wheel on the rear axle. There are four speeds of 5, 8½, 13, and 17 miles per hour. The principal point of interest is the steering lever; this has a knuckle-joint and a spring; when it is released the spring lifts it up, at the same time a spring-loaded spindle is released and this opens the compression, with the result that the motor stops. Similar mechanism is found in the phaeton. These vehicles are well finished in every respect.

The Bergmann moto-vehicle (*see* Fig. 19) is of German origin, but does not differ materially from the usual accepted types. The one illustrated is a handsome enough vehicle, and is well upholstered and fitted. It is termed the "Orient Express." The motor is of 5 H.P., constructed on ordinary lines, and calls for no special notice. Magnetic ignition is employed, thus doing away with accumulators and induction coils. The cylinder is water-jacketed, the water from the storage tanks in the sides of the rear portion of the carriage circulating under the action of gravity. On the return to the storage tanks the heated water is made to pass through a condenser. Three forward speeds and one backward motion are provided. On the crank-shaft is a drum, which is connected to corresponding pulleys on a forward intermediary shaft, which is also provided with a differential gear. In front of the intermediary shaft is a short shaft, on which are keyed, but free to move longitudinally along, three different speed gears, any one of which can, by a lever on the steering pillar, be brought into gear with corresponding spur-wheels on the intermediary. The latter wheels and the fast and loose pulleys are carried on a sleeve on the intermediary, the power being thus transmitted through one of the pairs of spur-wheels to the second intermediary and back to the differential shaft by a pair of spur-wheels constantly in gear, and from the latter to the rear road wheels by the usual sprockets and chains. The levers controlling the variable speed gear are also in connection with the belt-shipper, so that by placing the handle in a certain position the belt may be put on the central loose pulley and the motor thrown out of gear with the power-transmission mechanism.

FIG. 16.—CAMBIER "DUC."

The Compagnie Francaise des Cycles Automobile have attained a great deal of success and popularity with their autometette, of which we give illustrations (*see* Figs. 20, 21, and 22). As will be seen, it is a three-wheeled vehicle, the rear wheel being the driver. The motor is a single-cylinder horizontal petroleum-spirit one, developing, at a normal speed of 450 revs. per minute, a little over 3 H.P. It is placed on one side of the centre of the vehicle. The oil is stored in

2 Q 2

a tank under the seat, from which it flows to the carburettor, V. The latter is of the constant-level type provided with a float, V′. The regulation of the proportion of air and carburetted air admitted to the explosion chamber is controlled by the handle, A. The ignition is effected by means of an electric spark, the accumulator being placed at G, the induction coil at H, the contact button at P, and the ignition cam at B′, the handle, B, controlling the latter, being placed in the fore part of the carriage. The exhaust valve is controlled by side gear driven off the motor shaft. The cylinder is partly water-jacketed and partially provided with radial gills. The water-cooling tank, K, is fitted in the front of the vehicle; this tank is pierced by a series of tubes through which the air is free to circulate. The

Fig. 17.—Mors Touring Car, with Aluminium Canopy.

exhaust gases pass through a silencer, N, before being discharged into the air.

Fig. 18.—Mors Ordinary Car.

Two forward speeds are provided—7 and 14 miles per hour, but by varying the ignition a speed up to 20 miles can be obtained. The motor shaft carries two expanding friction clutches working inside the pulleys, X′X″. The pulleys, X′X″, which are mounted on sleeves, and so run loosely on the shaft, X, have rigidly connected to them, on one of their sides, small sprocket wheels connected by chains to corresponding sprockets, Y′Y″, on the intermediary shaft, Z. A driving pulley on the latter is connected to a large pulley, O, attached to one side of the rear driving wheel, by a belt, the power being in this way transmitted to the rear wheel. The belt normally runs slack on the two pulleys, and is only brought into action by lowering the jockey, G′, by means of the handle, C, which also controls the brake, S, acting on the large pulley, O. Thus, whenever it is necessary to apply the brake, S, the motor is always simultaneously put out of gear with the transmission mechanism by the slackening of the belt. A second brake—a band brake—is also provided, actuated by the foot-pedal, F, the band gripping a drum, F′, attached to the rear road wheel on the side opposite to the large driving pulley, O. The motor may also be thrown out of gear with the transmission mechanism by placing the handle, D, in a central position, neither of the clutches, X′ X″, being then in operation. The connecting-rod and crank of the motor run in an oil-containing bath. The wheels are of the cycle type, and are fitted with pneumatic tyres.

The Hille moto-tricycles (Fig. 23, p. 473) are, we think, likely to be received with considerable favour in this country. They are of German make, and hence scientifically constructed. They follow the usual lines as regards the transmission of the power, but some differences are noticeable in the carburation. The general design of the vehicle is shown in Fig. 24, p. 473. The motor is suspended from the rear axle and is of about 1¼ H.P., running at 1,200 revs. per minute. The carburettor is shown in Fig. 25, p. 473, and this consists

FIG. 19.—"ORIENT EXPRESS" (Bergmann System).

FIG. 20.—AUTOMOTETTE (Compagnie Française System).

of a simple triangular tank placed between the rear members of the frame. The carburation is effected by the ingenious method of passing the exhaust through the spirit tank, thus heating the spirit and producing a large quantity of available mixture, and it is by the quantity admitted that the speed is regulated. These vehicles are extremely well made and are powerful enough to be attached to trailers.

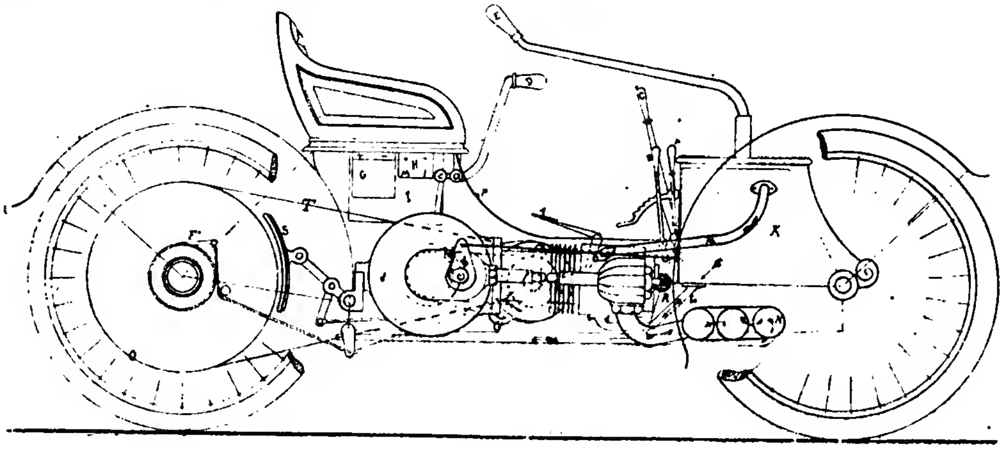

FIG. 21.—AUTOMOTETTE (Side Elevation).

THE INSTITUTE OF BRITISH CARRIAGE MANUFACTURERS.

THE eleventh annual autumnal meeting of the Institute of British Carriage Manufacturers took place on September 6th and 7th, at the Royal Hotel, Edinburgh, there being a large attendance of members. Bailies Sloan and Robertson on the first day welcomed the Institute on behalf of the Edinburgh Corporation. Mr. William Angus, J.P., Newcastle-on-Tyne, the President of the Institute, having returned thanks, gave his address.

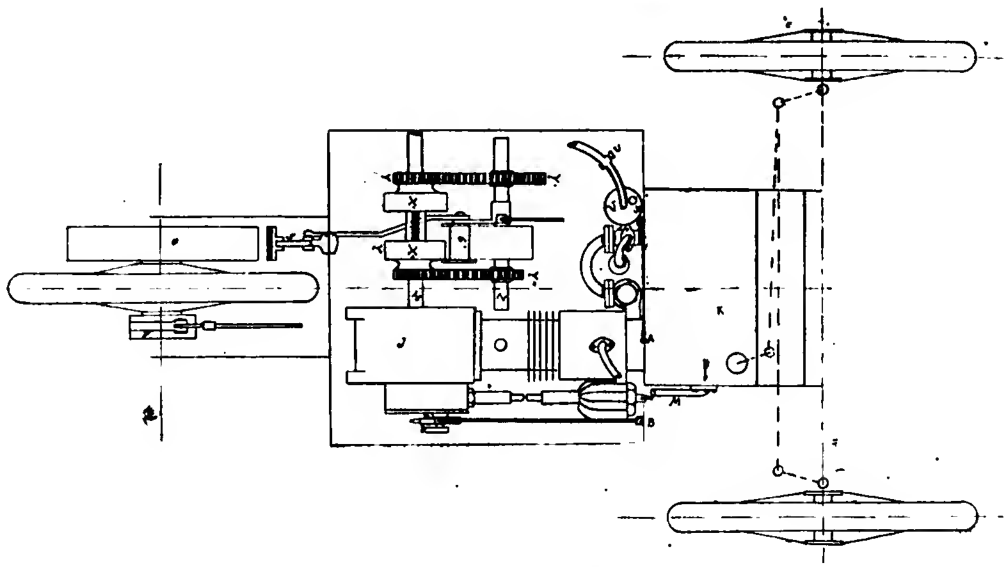

FIG. 22.—AUTOMOTETTE (Plan).

Choosing as his subject "Education in Coachbuilding," he said his thoughts had been guided in that direction by the important scheme which had been inaugurated by the Technical Education Board of the London County Council for the establishment of a higher technical day class for carriage-builders. They hoped that British coach-building might occupy the leading position which it had held in the past, that it might set and not follow the fashions. Among the subjects which a young coachbuilder ought to understand he would prominently put freehand drawing. The next stage should be to make drawings of every part of carriages, in plan, elevation, section, projection, and perspective. A knowledge of the principles of solid and plane geometry was also necessary for their trade. In their new higher technical class the link was being provided which would connect scientific mechanics with the actual work of their manufactories. The builder of a perfect carriage needed to be both a scientific man and an artist. On the motion of Mr. Percy Preston, London, seconded by Mr. Wm. Gilchrist, Lancaster, the President was cordially thanked for his address.

A paper was next read by Mr. T. Coward, London, on "The Application of Motors to Private and Public Carriages," which was illustrated by lantern views. After a historical sketch of the subject, he referred to several examples of steam moto-carriages—which form of power, in the opinion of independent and competent authorities, held the premier place to-day. The conclusions which were to be drawn from the competition organised by the Liverpool Self-Propelled Traffic Association last May and from previous experiences were, he thought, that steam for heavy work was superior to any other known force, and not only did he believe it to be the best available for goods traffic, but it was also available for large public vehicles, such as street omnibuses. There were some who were successfully applying steam to vehicles for lighter traffic. The great point of congratulation was the fact that the difficulty had been overcome by private enterprise. Electric propulsion for ordinary road vehicles in towns had now passed the experimental stage, the successful application of this force mechanically having been demonstrated. The serious drawback with regard to weight that had hitherto existed to condemn electrical road propulsion by accumulators was about to be removed, at least in a great degree, by the development in the art of accumulator manufacture. The facilities for electrical traction in America were much greater than here, because of the numerous

Fig. 23.—Hille Tricycle.

charging stations. Attempts, however, were now being made in London to render the electric car altogether independent of charging stations. His firm were building an electrical moto-carriage for Mr. Epstein, designed to be capable of self-charging. The motor was a dynamo also. A small oil-engine was carried

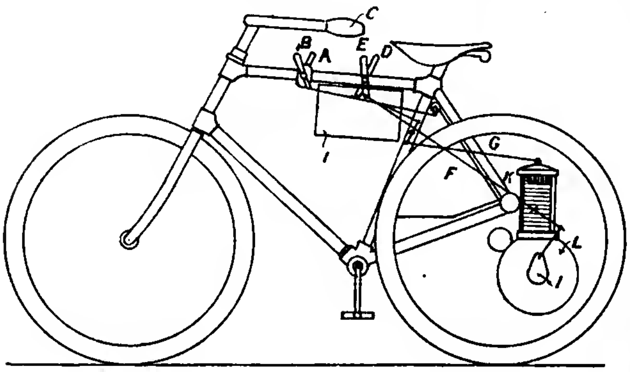

Fig. 24.—Hille Tricycle (Side Elevation).

on the car, so that when stopping at any time on the road, at an inn for the night, or for refreshment, the time could be utilised for recharging, by connecting the engine with the dynamo, for which suitable arrangement was made. Partial recharging could also be effected when running downhill. The form of motor which at present was the most popular and most in use was the oil-motor, of which there were various makers. He dealt with the principal features of the oil-motor, and with regard to its construction be thought that both the engineer and the coachbuilder should direct their efforts to the same object, and by a combination of their knowledge and skill no doubt the best results would be obtained. Of the three kinds of wheels that had been tried on moto-cars with more or less success—the ordinary carriage wheel wholly constructed of wood, the ordinary suspension iron wheel, and the one known as the artillery pattern—the latter had been more largely used by moto-car builders, and seemed best adapted for the purpose. For all moto-carriages running over five miles an hour a pneumatic or solid rubber tyre was most essential, and the objections that now existed in regard to ball bearings for heavy vehicles would, be thought, in a very short time be removed by the roller bearing. In conclusion, he remarked that though the moto-car industry had lately made considerable progress, it was still comparatively in its infancy, and though the application of motors to road carriages was beset by many difficulties (difficulties that were not encountered on the railroad), there was no doubt that the engineer, in combination with the coachmaker, would be able, by their united efforts, to make the autocar industry of this country an important branch of British manufacture. It was his opinion that there were great possibilities in store for the "application of motors to carriages" by all the forces that he had named: steam for heavy

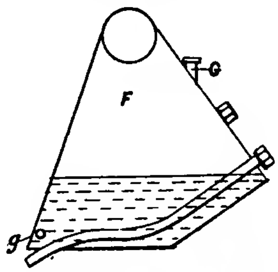

Fig. 25.—Hille Carburettor.

goods traffic and large public vehicles; electricity for smaller vehicles, public and private; petroleum for small goods traffic and private vehicles. But the direction in which the largest development of motor traffic would be likely to take place would be as a medium for more economically collecting produce from small towns and villages remote from railway stations, thus solving at once the problem of the light railway in an economical manner, and bringing about that which was so much desired, viz., cheap internal transport.

In the evening a dinner took place at the Royal Hotel, when the chair was occupied by the President. About 100 gentlemen were present.

Prior to the beginning of the second day's proceedings the Council of the Institute adjudicated upon the exhibits which had been sent in by workers in the trade, and for which prizes were given.

Mr. Andrew W. Barr, the secretary of the Institute, read a paper on "Coachmakers' Accounts," which was followed by a discussion.

Cells or Petrol Motors.—In a paper read before the Engineers' Club of Philadelphia, by Mr. Joseph Appleton, the latter makes a strong plea in favour of working moto-cars by storage batteries rather than by oil or gasoline motors. Briefly stated, he claims the following advantages for the electric vehicle over oil or gas motors:—Safety—a storage battery will not explode, nor is it inflammable, like gasoline or kerosene. Ease of handling and control—an electric motor, with its controller, is certainly the ideal method of control, and is distinctly not in the same class with the levers and valves necessary to operate an engine. Absence of noise and vibration—here, again, the electric motor is the ideal motor for the purpose, having a smooth rotary motion, instead of a reciprocating action with its noise and vibration. Absence of heat and smell—an oil or gas motor must, of necessity, be accompanied by considerable heat, and usually requires a water-jacketed cylinder. From the exhaust there is an objectionable odour, due to the unconsumed gases; but with the electric motor neither of these objectionable features exists. Cost of operation—there is no doubt, from independent tests made, that a vehicle can be propelled electrically with less consumption of energy than any oil or gas motor. There are many other points which might be touched upon, but these will suffice. For city use, the question of large mileage capacity does not handicap the electric vehicle in favour of the oil or gas motor, as the supply of electricity can be renewed as desired by recharging the batteries.

THE LUNDELL ELECTRIC MOTOR.

The following is a description of this motor, which is rather extensivoly used for traction purposes when the power required is small. It is the motor employed in the London electric cabs. Roferring to the drawings, Fig. 1 is a side elevation and Fig. 2 is a longitudinal section of the same, the section being taken on the line, x, x, Fig. 3, aud as seen looking in the direction of the arrows upou Fig. 3, which is an elevation of the right-band end of Figs. 1 and 2, the cap or end-plate of the oil chamber being removed. Fig. 4 is an elevation of the left-hand end of Figs. 1 and 2, with the journal bearing, the commutator, and detacbable parts removed. Fig. 5 is an end elevation of the left-hand end of Figs. 1 and 2, one of the commutator brushes and its means of support and the adjacent parts being shown in section. Fig. 6 is a central horizontal section taken through the body of tbe machine, the parts which support the ends of the field magnet cores being shown in plan, and the field coil, the armature, and its supporting shaft being omitted.

In the early machines of this type the structure is such that after the parts are once put together it is not possible to remove the armature without separating the field magnet cores and removing also the field magnet coil. This is because the field maguet cores are cast in semi-spherical form aud the field magnet coil inserted in position between these cores, tho journal bearings being integral with them. In the present machine the necessity of entirely dismantling it when it is desired to remove the armature and its attached parts is avoided by casting the two semi-spherical field magnet cores open at their outer ends and securing the journal bearings, commutator supports, and legs, or brackets, directly to the outer ends of the corea by bolts and nuts, the cores being secured together at their inner ends by bolts passing through lugs as before.

P, P^1, represent the semi-spherical field magnet cores, made preferably of cast magnetic steel, and such a shape that when put together, face to face, the pole-pieces overlap each other, and the cores form an annular space into which the field-magnet coil, M, fits, its axis being at an angle to that of the shaft, C, of the armature, A, such that the passage for tho insertion and withdrawal of the armature is not impeded by the coil. E E, E E, are lugs provided for receiving bolts, B^1, B^1, to secure the semi-spherical parts of the field magnet cores together.

The field magnet cores, P and P^1, are each cast from the same pattern, and are, therefore, duplicates, the extensions, I, being designed for the purpose of attaching to the upper part of the machine a screw-bolt or eye, H, for conveniently handling the machine in the shop. In the outer ends of the field-magnet cores are drilled holes to receivo bolts, B^1, and steady pins, B^5, for securing thoreto end-plates, R, R, or equivalent supports, these being preferably of magnetic material. They are shown as being so cast that their lower extensions constitute legs, L, provided with bolt holes to receive bolts, B^3, secured to slotted metallic supports, T, by nuts, B^2.

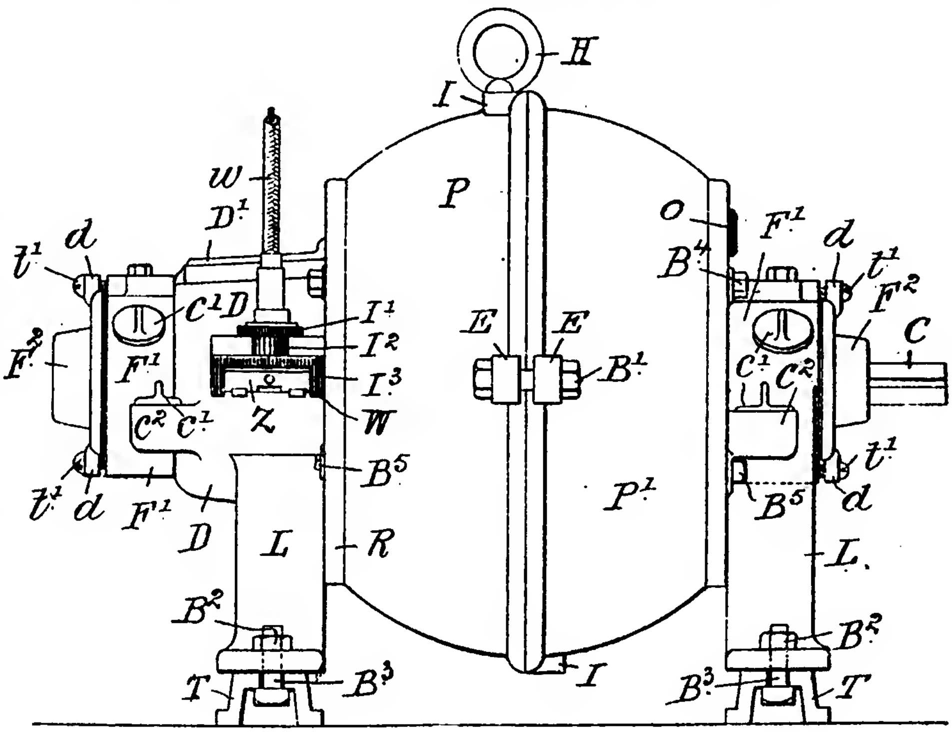

Fig. 1.

Fig. 2.

The end-plate or support, R, at the left hand of Figs. 1 and 2, is cast with a conical-shaped extension, D, provided at its lower side with an opening, O[1], for admitting air into the body of the machine, and an opening at the top, or upper side, to receive a door or cover,

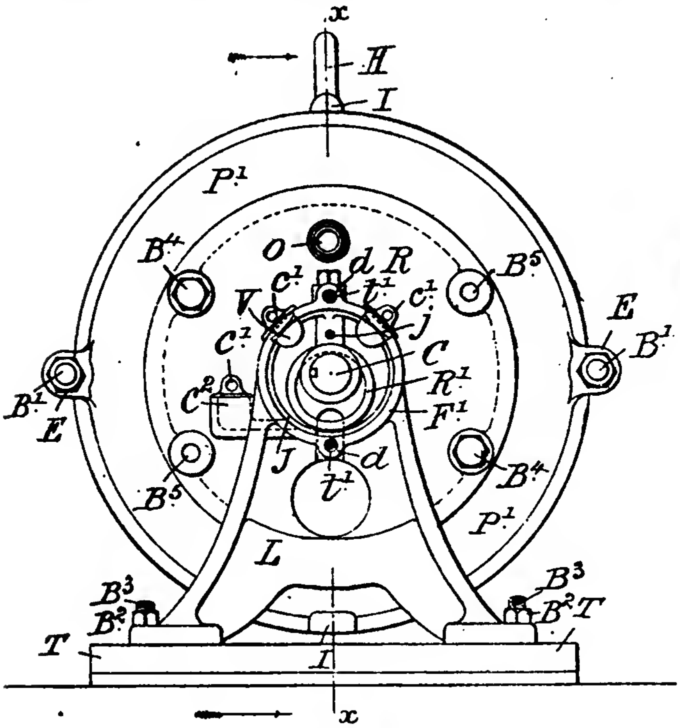

Fig. 3.

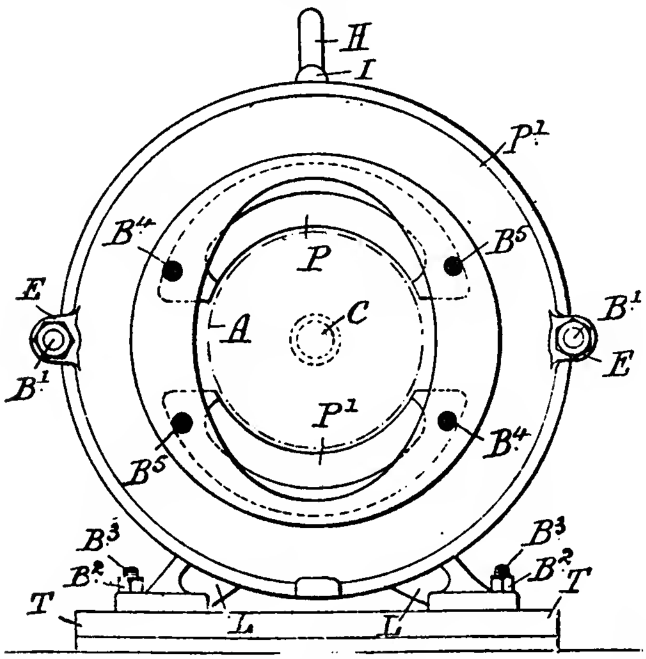

Fig. 4.

D[1], situated directly over the commutator for enabling it to be inspected. The commutator is supported by a cast metal sleeve, S, keyed directly to the armature shaft, C, the commutator strips, B, being insulated from this sleeve and secured by a disc, K, and screws, *t*, *t*, this disc and the opposite end of the sleeve, S, being undercut to receive the correspondingly-shaped strips, B. These strips may be connected to the windings of the armature, A, in the usual manner.

F[1] is a cylindrical extension cast with the other conical extension,

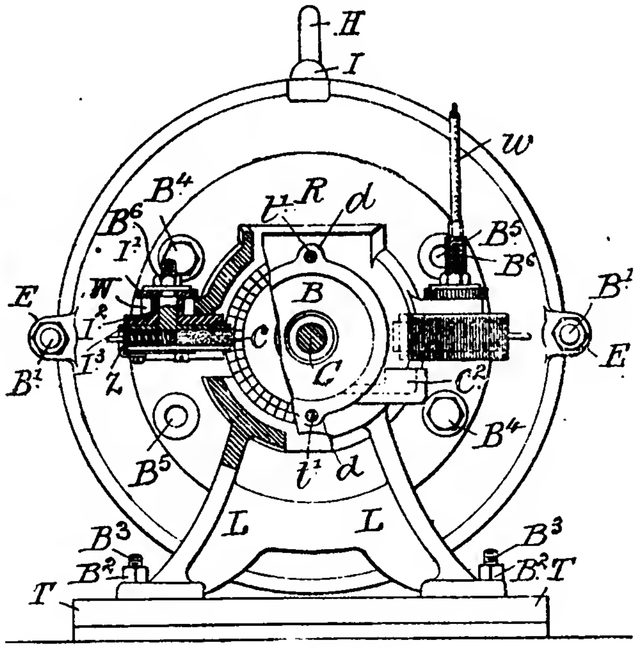

Fig. 5.

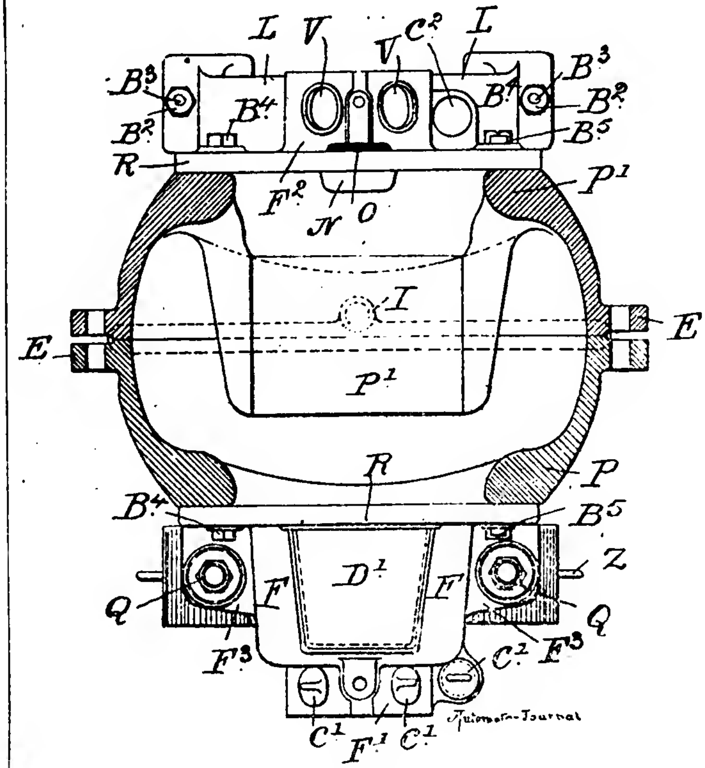

Fig. 6.

D. It has a bolt hole in its upper side to receive a bolt for securing the journal bearing, J; R[1] are oiling rings resting in slits in the journal bearing, J, and resting upon the upper surface of the shaft, C, and extending downward into an oil chamber constituted by the interior cylindrical portion of the part, F^1, and a detachable cup-shaped cap, F^2, secured to the outer end of the part, F^1, by lugs, *d*, and screws, t^1. The journal bearing, J, at the opposite, or pulley, end of the shaft, C, is formed and supported in a similar manner, being provided with oiling rings and with an oil chamber cast with the end plate, R; *j*, *j*, are pins extending through the upper flange of the journal bearings to retain the oiling rings, R^1, in place. c^2 are oiling ducts or channels for the introduction of oil to the oil chambers at the opposite ends of the armature shaft. V are peep holes for enabling the operation of the oiling rings, R^1, to be examined, and c^1 are caps for closing these ducts and peep holes. *c* are the commutator brushes, made preferably in the form of rectangular carbon blocks, and capable of sliding endwise to bear against the commutator under the influence of spiral springs secured in metallic brush guiding sleeves, W, attached to the body of the machine, but insulated therefrom by insulating material, I^1, I^2, and I^3. Z being a detachable cover and support for the springs to afford easy access to the brush and its attached parts.

B^5 are the binding posts, and *w* the conductors. O is a hard rubber thimble in the end-plate, R, through which the field-magnet windings are carried to a starting box (not shown in the drawings).

The oblong opening, O^1, through the part D, and the opening through the opposite end-plate, R, which supports the pulley end of the shaft, C, ensure sufficient ventilation for keeping the parts of the machine cool, by the passage of air indicated by the arrows in Fig. 2. By the arrangement of detachable end-plates, R, and legs or supports, L, these parts can be cast separately from the field-magnet cores and with the legs or supports, L, of any desired conformation.

TYRE MANUFACTURERS COMBINE.

A number of well-known tyre and manufacturing companies have, it is stated, formed themselves into an association for the protection of their interests, their object being to restrict competition and to resist payment of rebates and exhibition fees. The name of the new association is to be "The Pneumatic Tyre Manufacturers' Association," and the subscription has been fixed at ten guineas per annum. The following companies, among others, have joined the association:—The North British Rubber Company, the Palmer Tyre Company, the Amalgamated Tyre Companies, the Grappler Tyre Company, the Clipper Tyre Company, the New Ixion Tyre Company, the Preston Davies Tyre and Valve Company, the Non-Collapsible Tube Company, the Trench Tubeless Tyre Company, and the Tubeless Tire and Capon Heaton (Limited).

It is stated that it is intended to deal with the terms of guarantee under which members of the association usually sell their tyres, and it is possible that some arrangements as to prices for next season may be made. The association feel that the multiplication of local cycle shows is of very little real value to the trade, and as these have, it is asserted, been almost entirely run with their money, the benefits have certainly not been commensurate with the expenditure, and as a consequence the association has decided to limit its support of exhibitions to those held in London, Dublin, Edinburgh, and Liverpool. In plain English, this means that the tyre manufacturing companies find it absolutely necessary to cut down expenses.

The Limitations of the Trolley.—The limitations to the overhead trolley are now quite generally recognised. It has been found that it is difficult efficiently to transmit, by means of the ordinary form of trolley wheel, more than 150 ampères from the wire to the wheel without excessive sparking and loss. The speed at which a trolley wheel will stay on the wire, through section insulators, special work, and switches, is limited in good practice to not much over 10 miles an hour, says Mr. Pepper in the *Journal* of the Franklin Institute. When the trolley stand and wheel are both designed for high speed and the line carefully constructed, it is possible to run on straight-line work at a speed of about 30 miles an hour. Beyond this speed the tendency to throw the wheel from the wire, owing to slight obstructions on the trolley wire, is very great. If the wheel leaves the wire at this speed it is almost certain to either break the trolley pole or bring down a large portion of the overhead construction. It is for this reason that experiments have been and are being tried to substitute a fixed conductor near the ground with a large surface contact for the overhead trolley wire, for high speed and heavy currents.

NOTES OF THE MONTH.

The Manchester Ship Canal Company charge 2*s.* 6*d.* as toll for the transit of moto-vehicles over their bridges.

It is a very curious feature about not a few so-called "advanced" papers that they are among the most hostile as regards automobilism. Thus the *Review of Reviews* airs its views under the heading of "Moto-car Mania." Why mania? Of course this silly effusion is reproduced by *London*.

What is claimed to be the heaviest train on record drawn by a single locomotive was hauled on August 9th over the Pennsylvania Railroad from Altoma to Columba. The train consisted of 130 cars of coal, and had a length of 3,877 feet. The total weight behind the tender was 5,212 tons, of which 3,693 tons was paying load. The locomotive used weighed itself 104 tons.

According to the *Daily Chronicle* a new Flemish word has been coined to express the French word "automobile." It is "Snelpaardelooszonderspoorwegpetroolrijtuig." To be correct, if not already accepted, the word has at least been proposed at a session of the Flemish Academy at Antwerp. The great merits the new word possesses are its euphony and expressiveness.

Messrs. Carr and Co. (Limited), of Carlisle, are about to obtain delivery of a large automotor wagon, built by the Lancashire Steam Motor Company, Leyland. The wagon is intended for use in West Cumberland, and will probably do the work of four horses. It will be capable of carrying a load of 3 tons, at an average speed of five miles an hour. The wagon is fitted with a high-pressure boiler and is fired with liquid fluid.

An absurd canard has been going the rounds of the Press to the effect that the engineer-in-chief's department of the General Post Office is busily engaged considering tenders for the supply of motors to be used in connection with the postal service. The Post Office has been experimenting with motor mail vans, and several are actually running experimentally at the present time. Notwithstanding the success achieved so far the matter is still to an extent in the experimental stage.

The Kilmarnock magistrates have licensed Mr. W. A. Reid to run moto-vehicles as hackney carriages under the burgh regulations. Two motors have been placed on the route between Kilmarnock and Hurlford, one starting at each end every 20 minutes. The new vehicles are largely patronised. We understand that additional motors are shortly to be introduced on other local routes. The Dundee magistrates have granted permission to the Dundee and District Tramway Company to run three moto-vehicles between High Street and Magdalen Green, *viâ* the Esplanade, on Thursday, Friday, and Saturday.

For some time past the Devon Trading Company, of Axminster, had experienced considerable difficulty in hauling their goods from the Blue Seas Lime Works to Axminster, a distance of three miles. The road was soft and very narrow, and consequently the traction-engine used cut deep ruts, forcing the road up in the centre. Matters finally got so bad that the Company obtained one of the patent engines made by Messrs. P. J. Parmiter and Co., of Tisbury, which have a central roller wheel 4 feet wide, with the result that the condition of the surface has been rapidly improved. The engine is stated to have great tractive power.

As we go to press we understand that the municipal authorities of Westgate-on-Sea have reconsidered their foolish decision to sprinkle gravel on the roads with the object of rendering the passage of moto-vehicles difficult. These local bumbles have at length grasped the fact that a newly-gravelled road will be more severe on horse-drawn vehicles. At Margate the feeling against moto-vehicles is also very strong. At the latter place this feeling against moto-vehicles found expression in an assault committed by a local omnibus driver upon the driver of a moto-vehicle. This led to the former's appearance in the police court, and he was fined 10*s.* and costs.

A NEWLY announced substitute for rubber, named perchoid, the invention of Dr. Napier Ford, is described as an oil which has undergone a high degree of oxidation. The oil is heated with litharge, stirred long and continuously, and then allowed to cool. Specially prepared tow is then dipped into it and placed in wire baskets subjected to air. The oil admitted to the filaments of the tow thus becomes wholly oxidised. This is drawn through rollers and comes out a leathery material closely allied to, if not identical with, rubber. Its tenacity is increased by mixing sulphur with it. It is said that perchoid can be rolled as thin as a piece of tissue paper, and that it makes leather impervious to moisture, though not to air.

SAYS the Society correspondent of a contemporary :—Society is slowly dropping the bicycle in favour of the moto-car. In a year or so, if you have not your private motor you will no longer be "in the fashion." It is devoutly to be hoped that there will be moto-car schools, as well as bicycle schools, for the aristocratic amateur has already proved himself a source of grave danger to the pedestrian public in London. Lord Carnarvon, who was, I believe, one of the society pioneers in bicycling, has purchased two moto-cars, and has gone abroad with one of them for a tour. Lady Kitty Somerset and her husband have also succumbed to the fascinations of motoring, as well as Lady Alexandra Beauclerk, who contemplates a tour in company with Lady Kitty Somerset.

YOUGHAL now receives its mails by a moto-vehicle. The first moto-vehicle, imported by the Postal authorities for the delivery of the mails, lately made a successful experimental trip from Cork to Youghal. It left Cork at 8.34 a.m., having on board, besides the operator and the contractor's representative, Mr. G. A. Whitman, Assistant Surveyor, Post Office, and Mr. John Sheridan, Postmaster, Cork. It reached Carrigtwohill at 9.26, Middleton 9.53, Castlemartyr 10.29, Killeagh 10.53, and reached its destination, at the Youghal Post Office, at 11.51, thus taking 3 hours 17 minutes to do the journey, but from this must be deducted a five minutes' stay at each of the above-named places. The motor is a Daimler, and capable of doing 12 miles an hour. Everything worked well on the trial trip, those who travelled by it expressing themselves highly pleased. Its appearance on the roads, especially in the country districts, created great curiosity and wonderment, and large crowds collected opposite the Youghal Post Office to view it.

SIX of the new bogie single-wheel liquid-fuel burning express engines, designed by Mr. James Holden for the Great Eastern Railway, and built at the Stratford Works of that Company, are now out. They are numbered 10 to 15, taking the place of some very old locomotives which were scrapped. They have, says *Engineer*, 7-feet driving wheels, 18-inch cylinders, 160-lb. steam pressure, like the older single-wheelers, but the piston stroke is lengthened from 24 inches to 26 inches; the driving wheels have outside as well as inside bearings, the frames being double, and the weight is greatly increased, as much as 19½ tons being placed on the single drivers. The telescopic boiler is 11 feet long and 4 feet 4 inches in diameter. The fire-box is 7 feet long. The heating surface is :—Tubes, 1,178 square feet; fire-box, 114 square feet; total, 1,292 square feet; and the grate area is 21·37 square feet. The engines are fitted with Mr. Holden's liquid-fuel apparatus, steam sanders, water pick-up scoops, and exhaust steam injectors. They are employed on the heavy expresses between London, Ipswich, and Cromer.

A BELGIAN ministerial decree forbids the starting of gas and petroleum engines by pulling on to the spokes of the fly-wheel; and a specialist in such engines writes to the *Organe Industriel*, of Liége, drawing attention to the want of clearness in this decree, and also the grave consequences it may entail for the numerous industries in which such engines are employed. It is well known, he observes, that for starting an explosion motor at least two revolutions must be made before it receives a motive impulsion. For small motors it is quite safe and easy to give the engine a few revolutions by pulling the fly-wheel round by hand; but for larger sizes this work, if not dangerous, is fatiguing, and requires too many hands, so that makers generally provide their motors with self-starters, the principle of which is to introduce an explosive mixture behind the piston, to be exploded after the crank has slightly passed the dead point. This method does not dispense with acting on the spokes of the fly-wheel, since the crank has to be brought to the dead point. But it is not likely that the decree is intended to interdict that operation, any more than that of acting on the rim of the fly-wheel, when it forbids action being exerted on the spokes. The following method, intermediate between the other two, is also employed :—A cylinder full of explosive mixture is drawn in, while the fly-wheel is slowly turned for compressing this mixture, which is then ignited by turning the fly-wheel in the contrary direction, after which the engine will revolve in the normal direction. In this case action is exerted on the spokes or on the rim of the fly-wheel for two half-revolutions in contrary directions, and the fly-wheel is released directly the explosive mixture is felt to be ignited, so that there is no danger. Inasmuch as the decree aims at suppressing danger, the question is, says *The Engineer*, Wherein does the danger consist?

A FIRE EXTINGUISHING FLUID.—One of the best agents for extinguishing fires, according to the *National Druggist*, is aqua ammonia, without any addition whatever. "We have personally had experience with the almost marvellous power of this substance in this direction," says the editor of that journal. "In one instance, where fire had originated, probably from spontaneous combustion, in a pile containing several tons of cotton seed, and the interior of which was almost a solid body of live coal, a half-gallon of ammonia completely smothered the fire. In another, which occurred at Savenay, France, the vapours of a tank containing 50 gallons of gasoline caught fire in the linen-room of a laundry. The room was instantly a mass of living flames, but a gallon and a half of ammonia water thrown into it completely and almost immediately extinguished the fire. The ammonia was in a glass demijohn in an apothecary's shop next door to the laundry, and was thrown into the room by the druggist as an experiment. To use his own words in reporting the circumstance in the *Union Pharmaceutique*, M. Janneau, the pharmacist, says: 'The effect was instantaneous; torrents of black smoke rolled upward in place of flames, and in a moment every trace of fire was gone. So completely was the fire extinguished that workmen were enabled to enter the room almost immediately, where they found the iron tank of gasoline intact.'" Has the Fire Brigade of the London County Council tried this method?

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to THE EDITOR OF "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. KING AND CO., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents:—*

London: Wholesale—BRETT AND CO., 5, Pilgrim Street, Ludgate Hill, E.C.; MUNTON AND CO., 7, Red Lion Court, Fleet Street, E.C.
Birmingham: J. MCCANN, 37, Union Street.
Manchester: JOHN HEYWOOD, Deansgate.
Newcastle-on-Tyne: C. C. ROSS, 35, Side.
Paris: HOMÈRE MOREAU, 97, Rue Nollet.
Victoria (Australia): PHILLIPS, ORMONDE, AND CO., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

IMPORTANT ANNOUNCEMENT.

The current issue completes **Volume II. Price 9s.** (bound complete with Index).

The Index, which will be published free with the October number, will be very copious, and will include complete—

Alphabetical list of all New Companies Registered.
" " all Patent Specifications Published, carefully classified under subjects.
" " all Patentees' Names of Specifications Published.

For purposes of reference these particulars are likely to prove of immense value.

VOLUME I.

NOTICE.—A few copies of Volume I, bound complete, can still be supplied at One Guinea net, in consequence of our having purchased some of the numbers out of print, enabling us to make up some more complete sets.

Most of the back numbers can still be obtained at 6d. per copy, or 7d. per copy post free.

COVERS FOR BINDING VOLUMES.

Price 1s. 6*d.*; *Post Free,* 1s. 9*d.*

Can be obtained through the usual Agents, or direct from the Publishers.

Proprietors and Publishers—F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

SEPTEMBER 15TH, 1898.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month.

1898.

Oct. 6 to 12 .. Poids Lourds, Paris, organised by the Automobile Club of France.

Nov. 18 to 26.. Stauley Show of Cycles, Motor-Carriages, &c. Royal Agricultural Hall, Islington.

1899 .. .. Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.

" .. .. Motor-Car Exhibition at Tunbridge Wells.

" .. .. Heavy Motor-Vehicle Competition at Liverpool.

1900 .. .. Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

X. Y. Z. (Birchington).—We cannot recommend the Duryea moto-vehicle for the simple reason that we know nothing of the details of its construction. Why not try a Daimler, or Benz, or Riker? These we know.

CANTONESE.—Your great difficulty would be the supply of petrol at a reasonable cost. Millions of tons of burning oil are exported to China and Japan, but very little petroleum spirit. Consult Messrs. Samuel and Co., Houndsditch, London.

E. JONES (Coventry).—Friction discs wear rapidly and are very noisy. We cannot recommend the chain you mention because we fail to see that it has any mechanical advantage over the ordinary plate link chain. See Unwin's machine design.

JAS. KEELEY (London).—The Buffalo injector is not used, so far as we know, to any great extent on the railway in question. Gresham and Craven's is mostly used.

STEAM MOTOR.—The consumption of water in traction-engines is about 27 to 30 lbs. per B.H.P. hour, and the coal about 3 to 4 lbs. per B.H.P. hour. In moto-vehicles the consumption is about the same, small engines and boilers being usually very uneconomical.

FRICTION.—Morin's laws, although not exact, give very close approximations.

W. T. L. (Elgin Avenue).—The type of moto-car you refer to is now somewhat obsolete. It was, we believe, originally the design of a gentleman connected with the Elieson Lamina Accumulator Company.

J. A. L. (Mirfield).—Shall be very glad to purchase both No. 1 and No. 12, and will remit on receipt.

J. L. C. (Blackrock).—You will find the letter in No. 2, Vol. I. Copy has been sent you.

J. G. C.-G. (Hythe, Southampton).—The number of the patent is 10,081 (1897). The only suppliers of the improved Benz system manufactured by the Maison Parisiennes de Voitures Automobiles are the International Motor Car Company, of 15, High Road, Kilburn.

ROTARY MOTOR (Sheffield).—You must not blame us. Your claims do not particularly specify as being applicable to moto-vehicles. The great number of patents being taken out in connection with automobilism precludes our recording anything except where the claim applies particularly to moto-vehicles.

C. M. D. J. (Wistanstow).—(1) Not having made any personal tests of the vehicle in question we are unable to express any opinion. We are, however, promised a practical test by the proprietors. (2) We do not know. It has been promised for over a year now.

G. KESTER (South Wimbledon).—We do not know personally of any Daimler second-hand motors for sale, but would suggest your applying to any of the companies who are advertising in our Journal. They, no doubt, would be able to supply you with what you want.

F. HENDY AND Co. (Southampton).—We will add your name as desired on our next list as storing a large quantity of petrol and prepared to undertake repairs of motors. Specimen copy of the Journal sent.

THE HORSE-POWER OF PETROL MOTORS.

WE observe in some quarters that it is becoming a practice to employ the term "nominal horse-power" in connection with light oil—casually known as spirit or petrol motors. We wish to enter a protest against the introduction of such a misleading, erroneous, and unscientific term as nominal horse-power in connection with the petrol motor.

In the early days of the steam-engine the use of the term nominal horse-power had some justification, as it expressed, although in a crude and indefinite way, the power of the motor as a minimum. With the gradual increase in steam pressures, and the employment of accurate methods of measuring power, the nominal horse-power became a function of the indicated power; but with the introduction of "types" of engines the relation between nominal and indicated power became indefinite. Of late years the term nominal horse-power has nearly wholly dropped out of use even by commercial men who, as a rule (witness our weights and measures), cling tenaciously to inexact terms. Needless to say, in the scientific nomenclature of engineering nominal horse-power is meaningless and archaic. Its use by any engineer is a sure and unmistakable sign of a neglected or imperfect professional education. We are aware that the term still finds a place in the catalogues of not a few very eminent traction-engine builders; the reason is that the bulk of the customers of these firms are farmers who know perfectly well what they mean by a 10 nominal horse-power traction-engine, but who do not know, and who do not care a jot whether this engine indicates 30 or 40 horse-power, and who are sublimely indifferent to the relation between brake and indicated horse-power. With this exception, the term nominal horse-power is, as we say, obsolete. We now see its resurrection by manufacturers of petrol motors, in one of whose catalogues we see a motor spoken of as being "4 horse-power nominal and 5½ horse-power actual." Inquiry fails to elicit any definite statement of what the nominal horse-power of a petrol motor is and what is the actual, and also what is the relation between the two.

The statement that a motor is of 5½ horse-power actual is in itself vague. If it means that this is the indicated horse-power which is an "actual" power, then the effective or brake or again "actual" available horse-power will be perhaps 4½ or 4¾. If this 5½ actual horse-power be the brake-power, then the indicated power will be perhaps 6½. Brake and indicated horse-power are well understood and definite expressions, and both are "actual" entities. Why, then, introduce the confusing and misleading term nominal horse-power? If a motor is of 4 indicated horse-power and of 5½ brake horse-power, why not say so, rather than say it is of 4 horse-power nominal and 5½ horse-power actual? The former statement is plain and straightforward and strictly scientific. It also conveys to merchants and buyers a definite meaning. The latter statement is indefinite and unscientific, in that a wholly meaningless and obsolete term is employed. A person who purchases a 5 nominal horse-power oil motor could not recover if it failed to develop more than this, because the nominal horse-power is an indefinite and unscientific unit, neither could he if he purchased a 5 actual horse-power engine which only gave off 4½ available or effective horse-power. Indeed, for the sale of moto-vehicles we think the introduction of the term horse-power superfluous. Of course, in analytical writings such as appear in The Automotor, we have to employ the terms brake and indicated horse-power. We would personally much prefer to employ poncelets. So far as the relations between a seller and a purchaser are concerned we think it would be better, and certainly simpler, to conduct the transaction on the explicit statement that on a stated kind of road and grade the vehicle and its load would be moved at a stated minimum speed upon a minimum consumption of oil and water or other source of energy. Such a specification contains no reference to horse-power units of any kind. Another reason why it would be advisable to employ horse-power units as little as possible in, at any rate, commercial transactions, is the difficulty of measuring accurately the power of small rapidly-reciprocating petrol motors. The brake test, although simple and free from error, does not tell us how much is lost in friction and transmission. For our own part, we always regard statements concerning the power of these small motors with considerable doubt. Before the Liverpool trials we urged that the competing vehicles should be blocked up and the engines indicated and the power absorbed by the brake test determined. This, we regret to say, was not done. But such a test will be carried out some day, and many people will be surprised at the large amount of power absorbed between the cylinder and the driving wheels. With electro-motors the measurement of power is simple enough, the readings of the volt and ammeter give the watts, and therefore the power with little or no calculation, with the advantage that the accuracy can be as close as we please. With electrically-propelled vehicles we can specify horse-power without the slightest question being raised as to "nominal" or "actual" horse-power. With steam and petrol motors we have to consider whether the power is that indicated or is that actually available, but this knotty point is now further complicated by the introduction of the obsolete term nominal. Why?

THE ADVANTAGES OF MOTO-VEHICLES FOR MUNICIPAL SERVICES.

After the very emphatic opinion expressed by the Post Office authorities in the Postmaster-General's Report, which we publish elsewhere, viz., that "so far as the experiments went they showed that moto-cars were likely to prove in the near future a mode of conveyance for letter and parcels mails which would be attended with advantage both as regards speed and economy," we may well congratulate all concerned in this very satisfactory result. Automobilists need not now waste their time in convincing, or rather in trying to, the "many-headed." It will be sufficient to refer doubters to the Post Office Report for 1898. The era of experiment is now passed, and carriers, tradesmen, and others have the best possible assurance that moto-vehicles can be produced which may be employed with advantage "both as regards speed and economy." For municipal purposes moto-vehicles are eminently suitable, and their use will be attended with a most pronounced saving in the rates. When, however, it is proposed to employ moto-vehicles there will, of course, be the inevitable garrulous county or town councillor or vestryman—men almost invariably of small intellectual capacity and knowledge—who, with a natural desire to protect their own or their friends' vested interests, will give utterance to that venerable but very stale aphorism to the effect that "moto-cars are in their infancy." This absurd expression of opinion is too often regarded as indicative of profound and cautious wisdom. We would like to ask—How is it that the London County Council does not employ moto-vehicles? Perhaps some of our readers will explain.

SPECIFICATIONS OF TRAM RAILS.

In establishing a municipal system of traction, whether by horses, steam, or electro-motors, a large proportion of the cost is absorbed by the permanent way, and this cost is needlessly enhanced by the absence of anything like standard rail specifications, owing to which each municipal engineer does that which is right in his own eyes, and, of course, in specifying for rails a splendid opportunity presents itself of airing one's metallurgical knowledge—or, generally, want of knowledge. On the Continent light railways or tram lines are cheap because the rails are made in scores of mills all over the country to standard specifications, and hence are cheap. Moreover, the proprietors of the lines are saved the enormous inspecting and testing fees. An interesting instance of British methods is afforded by the municipalities of Glasgow and Halifax. Both municipalities want tram rail. Glasgow specifies for a steel of the following composition:—

Carbon, 0·55 to 0·65 per cent.
Manganese, 0·80 to 1·00 per cent.
Phosphorus, 0·06 per cent. (not to exceed).
Sulphur, 0·05 per cent. (not to exceed).
Silicon, 0·15 to 0·20 per cent.

The weight of these rails is to be 98 lbs. per yard.

Halifax specifies for a steel containing:—

Carbon, 0·28 to 0·40 per cent.
Silicon, 0·06 per cent. (not more than).
Phosphorus, 0·07 to 0·08 per cent. (not more than).
Sulphur, 0·06 per cent. (nor more than).

The chemical compositions of, and hence the physical qualities of, these rails differ widely. In both cases the rails have to perform the same work and under practically the same climatic conditions. A steel-maker tendering for the supply would have to quote at a high figure because he would have to make a series of chemical and physical tests in each case to arrive at the proper mixtures.

Now, both these specifications differing so widely cannot possibly be right. If 1 per cent. of manganese is necessary for the rails of Glasgow, and if its absence, or its presence in a lesser quantity, will cause a parcel of rails to be rejected, it is fair to assume that the ratepayers of Halifax will suffer damage because their rails will languish for the lack of the sustaining and necessary manganese. Similarly Halifax is not greedy in the matter of carbon; it likes a soft, well-wearing metal, and so is content with a modest quarter to one-half of 1 per cent. Glasgow, on the other hand, likes a hard rail, and so insists upon more than one-half of 1 per cent. of carbon, and, just to season the mixture, requires a dash of sulphur thrown in. As to the specifications themselves we express no opinion. Assuming, however, that the one represents scientific engineering practice, then the other does not, and *vice versâ*, and this means that one or the other Corporation will be paying a needlessly enhanced price for its rails. It would be interesting to know which specification is the most in conformity with the science of the thing, and which, therefore, is calculated to produce the most economical rail. Ratepayers should in their own interest try and find out the reason for this extraordinary divergence. After all, why not have standard rail specifications?

THE POSTMASTER-GENERAL'S REPORT.

The Annual Report of the Post Office has just been issued. The following is a *précis* of the more salient features:—

Tho letters delivered during the year numbered 2,012,300,000, the postcards 360,400,000, the book packets 727,300,000, and the parcels 67,823,000.

The growth of the letter post has been double that of last year.

Twice as many postcards were used as 10 years ago.

Newspapers formed the only department of Post Office literature which showed a falling off.

During two years the express delivery service has doubled.

There were 720,172 undelivered letters.

The number of letters posted without address was 38,860.

Four hundred and thirty new post offices and 1,231 new pillar and wall letter-boxes have been added.

The total number of offices open on March 31st last was 21,197, and the number of pillar and wall boxes 30,303.

The postal orders issued numbered 71,380,975, representing £26,014,583.

The number of deposits and withdrawals in 1897 was larger than in any previous year, but the total amount deposited fell somewhat short of the total for 1896.

During the year 83,029,999 telegrams were sent.

Tho staff of the Post Office has increased from 144,700 to 150,110 persons.

Referring to the experiments undertaken by the Department with moto-vehicles, the Report says:—

An oil moto-car, the property of the British Motor Syndicate, was engaged for a week in October for the conveyance of letter mails between the General Post Office and the South-Western District Office, and again a fortnight later for the conveyance of parcel mails for a week between the South-Western District Office and Kingston-on-Thames. Tho arrangement with the contractors for the London van and cart services admitted of the temporary transfer of this work, because the contracts, while fixing the rates for the several kinds of vehicles employed, leave the Postmaster-General free to diminish or increase the quantity of work at his pleasure.

For the oil moto-car a nominal charge was made of £1 6*s*. a week, said to be the out-of-pocket expenses of the Syndicate, whereas for the service which the moto-car displaced in the first week about £6 would, under the contracts, have been paid; and for the service to Kingston, which it displaced in the second week of trial, there would have been paid the sum of £5 7*s*. The moto-car performed the work in each case with great regularity and in somewhat less time than the horse conveyance ordinarily employed. The experiment was not pursued, as the car was not specially constructed for mail work, and the British Motor Syndicate preferred waiting before making further experiments, until they were in possession of a more suitable car.

The next experiment was with a steam moto-car, the property of Messrs. Julius Harvey. The number of parcels for despatch by the London and Brighton Parcel Coach had for some time been considerably in excess of the load which the coach could carry, and the steam moto-car was engaged between London and Redhill for six weeks, from December 16th, for the conveyance of the overflow. The price charged was £7 a week, as compared with an amount ranging from £11 8*s*. to £14, the estimated cost of a pair-horse van of like capacity. After the expiration of the six weeks the car was taken off and overhauled, and it again worked for a second term of three or more weeks on the same road and at the same rate of payment. An accident occurred on one occasion through a tube giving out, but, as a rule, the journey between London and Redhill of 24¼ miles out, 23¼ return, was performed in from 10 to 20 minutes within the time allowed for a horse conveyance.

An electric moto-car, the property of the Electrical Vehicle Syndicate, was also employed by four weeks on town work. One or two accidents occurred which led to delays, such as the slipping of a rubber tyre and the displacement of a screw, but in other respects the work was satisfactorily performed. The charge per week was £3 10*s*. as compared with £6 19*s*. 3*d*., which would have been paid under the London contracts.

So far as the experiments went, they showed that moto-cars were likely to prove in the near future a mode of conveyance for letter and parcels mails which would be attended with advantage both as regards speed and economy.

Arrangements have since been made for extended trials in London, on the Redhill route, in the neighbourhood of Reading, and also in Scotland and Ireland. It is confidently hoped that they will show that motors can be permanently used with advantage to the Mail Service.

LES POIDS LOURDS.—2nd CONCOURS.

The second competition organised by the French Automobile Club is fixed for October 6th to 12th next, and will be held at Versailles over the same routes as last year. The following are the entries at the time of writing:—

No. 1. Delivery van, by Panhard and Levassor (petrol).
„ 2. Omnibus, Roser (petrol).
„ 3. Delivery van, Middé (electric).
„ 4. „ „ Compagnie des Electromobiles (electric).
„ 5. Omnibus, 20 seats, De Dion et Bouton (steam).
„ 6. Char-à-banc, 24 seats, De Dion et Bouton (steam).
„ 7. Van, De Dion et Bouton (steam).
„ 8. Towing carriage, De Dion et Bouton (steam).
„ 9. Van, Valentin Pursey (petrol).
„ 10. „ De Dietrich (petrol.
„ 11. Delivery van, De Dietrich (petrol).

It is noteworthy that so far only one firm of steam moto-vehicles is competing—MM. De Dion et Bouton; neither MM. Scotte, Le Blant, nor Weidknecht are, we understand, likely to enter any vehicles. Indeed the general opinion seems to be that after the Paris trials of last year and the Liverpool trials in the early part of this, together with the recent Paris cab trials, sufficient information has been obtained to enable a pretty correct judgment to be formed as to the advantages and possibilities of the various systems of automobilism. Nevertheless, the forthcoming trials will add considerably to our knowledge of the recent developments in petrol motors. The trials will be conducted by M. Forestier, who will have with him a large staff of observers.

Automobilism and Sanitation.—The Sanitary Institute will hold their Annual Congress at Mason's University College, Birmingham, from September 27th to October 1st inclusive. During the session Mr. E. Shrapnell Smith will read a paper entitled "Somo Sanitary and Allied Advantages attending the Introduction and Use of Moto-Vehicles." From the practical knowledge which Mr. Shrapnell Smith has of this subject it should prove a valuable and interesting part of the Institute's programme, and we hope that the members will show their appreciation of the importance of the automotor industry by passing unanimously a resolution, which we understand will be moved by Mr. Shrapnell Smith, to the effect that the Sanitary Institute "is of opinion that the introduction and use of moto-vehicles should be encouraged by municipal, urban, and other authorities, in view of the fact that such departure will contribute to the general improvement of the sanitary conditions of our thoroughfares, and will effect economies under several heads of public expenditure."

Fig. 1.—Toward Tractor and Lorry.

Fig. 2.—Toward Tractor (Back View).

THE TOWARD STEAM MOTO-TRACTOR.

In the last issue of The Automotor we briefly described the steam tractor that Messrs. Toward and Philipson have designed and built for hauling omnibuses, lorries, &c., in Newcastle. We are now enabled to give an official description, together with illustrations, of this vehicle. Fig. 1 shows the tractor hauling an ordinary lorry. It will be observed that the fore-wheels of the latter are removed, the fore part of the body being carried on the rear end of the tractor, which is fitted with a turntable with an adjustable screwed spindle. In the view given this feature is not very apparent, owing to the view being obscured by a person standing in the foreground. By this means the major portion of the load on the lorry can be transferred to the rear part of the tractor, and this increases the load on the rear-wheels (the drivers) of the latter, and consequently the adhesion. It will be readily seen that almost any vehicle can thus be attached. This is an advantage peculiar to the tractor, and one which merits greater attention than has yet been given to it, as it affords a convenient means of getting the fullest benefit from the Locomotives on Highways Act. On a weight of 1 ton a very strong, simple two-wheeled lorry could be built that could safely carry 5 tons, and if all the weight allowed by the Act—viz., 3 tons—is put into the tractor, a much more substantial vehicle can be produced. Generally the practice is to construct the moto-vehicle to carry passengers or goods in addition to its own propelling power; this means that a large percentage of the available weight is utilised in providing carrying capacity, and hence the motor and boiler have to be of light scantlings. The tractor system, of course, means in effect an articulated six-wheeled vehicle, and, as the Liverpool trials showed, such a vehicle is difficult to manœuvre up a back street. This, however, is a matter of but small moment, and we understand that Messrs. Toward have not experienced any difficulty in regard to it.

A general idea of Messrs. Toward's tractor will be gained from Fig. 1, while Figs. 2, 3, and 4 are views of the boiler and motors as seen from the foot-plate, &c.

The frame is of L steel made as wide behind as the driving wheels will permit and reduced in width at fore part to clear the steering wheels and support the boiler. This frame is suspended on four laminated springs; the rear ones, being attached to the axle boxes in the centre, are allowed to work free at the ends, being thickened to work on hardened wearing plates; the front ones are attached

FIG. 4.—TOWARD TRACTOR.

FIG. 3.—TOWARD TRACTOR.

in the usual way to the frame and axle; the latter is pivoted at each wheel, thus dispensing with fore-carriage and turntable. The floor-plate is extended over the sides of the frame and forms the front wheel cases; the front portion is cased all round excepting two openings, one on either side of the driver's seat. From the frame, which is well braced, depend the side frames, locomotive fashion, with horn-plates, for the boxes of the axle and adjustable bearings for the crank and intermediate shafts.

The employment of horn-plates has been persistently advocated in The Automotor for these moto-vehicles, as in no other way can the severe longitudinal stresses, set up when passing over a rough road, be satisfactorily provided for.

One of the features of this tractor is that the road wheels are built entirely of steel upon a cast-steel hub; with more than usual care, each spoke is fitted accurately into its recess, the other ends have T-heads and are riveted between two angle-rings by machine, the tyre is then shrunk on to the angle-rings and riveted to them; outer wearing pieces or tyres are then riveted on with double countersinks so that they cannot come loose. This method has so far been most satisfactory in practice.

The motor consists of a pair of vertical inverted compound engines, 4″ + 8″ × 6″; these are placed over the main shaft just in front of the boiler, as seen in Fig. 2, the steam pipe from the high-pressure exhaust to the low-pressure valve chest acting as a receiver. The low-pressure engine can, however, be worked at high pressure, if required, by means of a bye-pass. These engines can develop on occasion 25 I.H.P. at 400 revs. per minute. They are fitted with long connecting rods and ample wearing surfaces, and are designed to run for long periods with the least attention. The first motion shaft gears with an intermediate shaft which has two speed gears and the usual differential gear; on each end of it are two sprocket wheels which transmit the power to the road drivers by chain, the pitch of the links being 6 inches. The engines are geared to the driving wheels at six to one and three to one for the two speeds of four and eight miles an hour respectively. The tractor is fitted with two powerful independent brakes, one a pedal hand brake, and the other a screw brake acting on the driving wheels; with either the tractor can be brought to a stand with a full load on any hill. The controlling levers and drain cocks are all arranged very conveniently for the driver. Lamps are fitted at each side showing red lights behind; an alarm whistle is also fitted. The steering is done by worm and wheel gear.

Steam is supplied by a rectangular water-tube boiler, shown in Figs. 5, 6, and 7, the tubes being horizontal and connecting at each end with waterspans; the objectionable feature of flat surfaces under pressure is obviated by fitting heavy screwed stays, as shown in Figs. 6 and 7. As will be seen, the heating surface and grate area are very large in comparison with the total volume, and we understand, as we should surmise, that the boiler will give more steam than the engine can use. We have always in The Automotor urged the importance of providing large heating surface and ample steam-raising capacity, and no doubt much of Messrs. Toward's success is due to attention to these important points.

The space around the boiler is utilised as feed tanks and bunkers. Water sufficient for a run of 20 miles can be carried in the former, while the quantity of fuel (coke) that can be carried suffices for a run of 60 miles. The average speed attained when hauling a wagonette filled with passengers is about seven miles per hour. So far as their experience goes Messrs. Toward are fully satisfied with their system, and have several orders in hand for their tractors. Their system seems to be very suitable for a hilly country such as Northumberland.

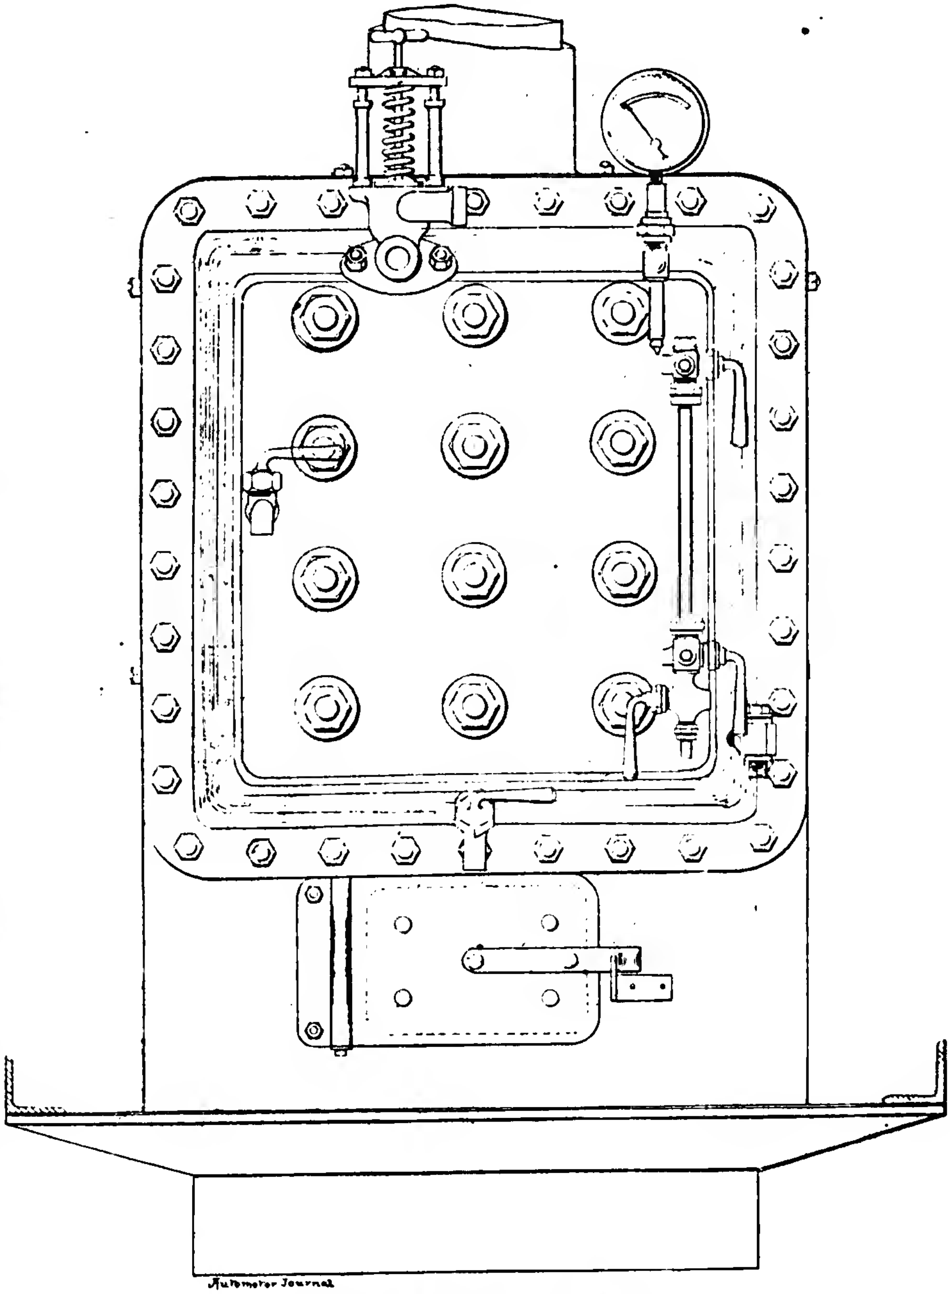

Fig. 5.—Toward Boiler (Elevation).

The most recent vehicle built by Messrs. Toward is one to the order of Messrs. Noble and Thompson, Morpeth. It is for use in

FIG. 7.—TOWARD BOILER (Longitudinal Elevation).

carrying coals and general cartage work in Morpeth and the neighbourhood. The vehicle was delivered on Saturday, the 3rd inst. The motor is a compound steam-engine, which carries coke and water sufficient for a journey of 15 miles. It has two speeds—one five miles per hour, and the other 2¾ miles. The cart or wagon is built of the usual hard wood, and has holding capacity for 3½ tons of coal. It is tipped up by a toothed rack and emptied by its door being made to swing. To the wagon there are fitted two powerful strap brakes on the driving wheels, and on the motor are friction brakes. It has also a steam whistle for alarm, and the regulation lamps. It left Pilgrim Street, Newcastle, with a 3-ton load of rubbish on the date mentioned, at two o'clock. It was driven by Mr. Meek, of Messrs. Toward, who had with him a stoker. In No. 1 motor wagonette there accompanied it Messrs. T. and W. Toward and Mr. William Philipson. Good time was kept and the distance done without a hitch. South of Stannington Mr. Noble met them, and he was so satisfied with the way the car went down the steep bank at Stannington Vale and up the opposite one, that he decided not to put it to the test of doing the Station and Stobhill Banks at Morpeth, as agreed upon. It was accordingly driven straight to the Quarry Bank east of Morpeth, which is the longest and steepest in the neighbourhood. Both the ascent and descent were accomplished in a most satisfactory manner. The load was emptied at the foot of the bank, and the car and cart driven into Morpeth, where they were stabled in Mr. Stafford's timber yard, Well Way. All concerned regarded the trial as eminently satisfactory.

REVIEWS OF BOOKS.

"La Voiture de Demain." Histoire de l'Automobilisme. Avec 250 figs. Par John Grand Carteret. (Paris: Libraire Charpentier et Pasquelle, 11, Rue de Grenelle, 1898). Prix, 5 francs.

In his preface the author points out that most of the works on automobilism are too dry, because too scientific, for general reading, or else the subject is handled in a vulgar manner interesting only to enthusiastic amateurs. Our cycling Press is a good instance of this. To the trained engineer the matter is, as a rule, so much uninstructed and ignorant babble. To the ordinary educated reader it is intensely dreary, but to the unscientific amateur it is of the most profoundly absorbing interest. One can find in a score of engineering textbooks the science of locomotion, whether on cycles or moto-vehicles, fully expounded, so can one find a score of journals on which the same subject is treated as a pastime or sport, but there is even yet plenty of room for a work in which cycling is treated in the same way as our author treats automobilism; that is, a work which shall be "historical, philosophical, anecdotal, and at times a little technical"—in a word, a work which interests the general reader. In the present volume this principle has been followed with considerable success, and there can be no question but that the matter is distinctly interesting. The history of automobilism, like that of most modern developments, can be pleasantly and profitably studied by a reference to the caricatures to which it gives occasion, and when automobiles first began to excite the Parisians it was only to be expected that such a promising subject of satire would be fully taken advantage of. Throughout the book we find abundance of caricatures, not only French but English, and not only relating to modern but to early automobilism. The more serious aspect of historical automobilism is well done, and the author has evidently been at great pains to obtain the earliest drawings relating to the art of locomotion. Many of these reproductions are of extreme historical value and very suggestive: thus we have a reproduction of a sculpture, dated 1760, showing an automobile gun and carriage. The gun is apparently loaded at the breech, and as the means of obtaining the motive power are not shown we are led to ask, Was Mr. Maxim anticipated? The earliest caricature is an English one, and is dated 1819: it is entitled "Going to the races," and shows an apparently military man and his lady being driven by five footmen mounted on hobby horses.

The work is divided into 10 chapters. The first is philosophical, and is intended to demonstrate the logical necessity of mechanical locomotion. The second chapter is historical. Here the author displays considerable learning, research, and, let us add, impartiality. He traces the germ of automobilism to the Egyptians, and do we know for certain that Hiero did not apply reactive steam-engines to the propulsion of vehicles and boats? Our author also sees the germ of the idea in the works of Salomon de Caus, Kercher, Dobozinski, Schoot, Worcester, and Papin. He gives an extract of a letter written by Roger Bacon in 1618, in which is clearly foreseen the possibility of locomotion without the aid of animals. We also learn that Jean Hautzch, of Nuremberg, in 1649 saw the possibility of "heat as a mode of motion," just 200 years before the great Tyndall published his classical work. Hautzch actually had a machine running in the streets of his native city. In this period mechanically-propelled vehicles were regarded as either miraculous vehicles or else as inventions of the devil. Newton's steam carriage is described. The engine of this vehicle, by the way, is clearly what a modern patent lawyer would term a colourable imitation of Hiero's motor of 2,030 years ago. Coming down to the eighteenth century, we have short but interesting accounts of the works of Robison, Darwin, Boulton, and others, not omitting the justly celebrated Cugnot (1770), whose vehicle is still in existence, and one of whose descendants is a well-known French journalist and automobilist. Watt, Read, Symington, and Trevethick are also mentioned, and their troubles. At the end of this (the eighteenth) century automobilism was occupying the attention of many persons both in England and France, as our author truly remarks. It was a period fertile in inventions and projects; there were two really practicable steam vehicles—that of Cugnot in France, and that of Trevethick in England. Both these distinguished inventors were, in the modern jargon, "born before their time," and both died broken-hearted.

Automobilism as a popular means of locomotion may be said to date from the early part of the present century, and as most of the practical efforts and experiments were chiefly made in England, our author devotes a chapter to describing them. Much of the information given is new and of considerable historical value. It has been dug out of all kinds of literary storehouses. The author would appear to have spent much time in ransacking the public libraries both in France and England. Many of the illustrations of these early vehicles are of extreme interest. In this chapter the efforts, successes, and the trials of Church, Gurney, Hancock, Squire, and Sir Charles Dance are well told. We need not dwell upon this part of the work as it is not flattering to our vanity, either as a practical or civilised people. We are, thanks to the School Boards, gradually breaking down the walls of prejudice, and a modern automobilist can through the Press be sure of at least a fair consideration of his cause. Chapter IV is an account of the progress of automobilism in France up to 1870. Chapter V describes the progress of automobilism in both countries up to 1870, as depicted in the comic journals. We have here a series entitled the "March of Intellect," containing many allusions to automobilism. Thus the "Grand Vacuum Tube Company" takes passengers from Greenwich to Bengal. A cartoon, by Alken, is reproduced, showing Regent's Park in 1831. All the vehicles are self-propelled. Another by the same artist gives a view of the Whitechapel Road, showing the steam coach, "The Infernal Defiance," racing with "The Dreadful Vengeance." The French caricatures are equally indicative of public opinion. Chapter VI deals with the period of 1870–1898, and in it all, or nearly all, the modern types of moto-vehicle are illustrated and described from the historical point of view. Most of the illustrations have, however, appeared in the pages of The Automotor. Chapter VII is an attempt to forecast the form that moto-vehicles of the future will take. Here our author allows his imagination to run away with him, and we hardly think that vehicles will ever assume the grotesque forms he gives them. Some of the designs are very artistic and appropriate; such, for instance, is the design for a moto-vehicle for the "Cordonnerie du Chat Nois," on p. 239. Another elegant but *genre* design is that of M. Gaslon-Charles, on p. 247, while an automobile for a newspaper has a duck in front—hardly the most complimentary, but decidedly a very allegorical allusion. Chapter VIII deals with contemporary caricature, and a very amusing one it is.

Considerations of space forbid us to mention the many good things it contains, and the same reason prevents us from dealing with the remaining chapters. In conclusion we can say honestly we know no better work on automobilism. It is exceedingly well written and entirely impartial. No attempt has been made to exalt any one nation or individual. The merits of all are fully acknowledged, and at the same time proper judgment has been observed. We have read the work with great pleasure, and can cordially recommend it to all who would know the history and social influence of automobilism.

"The Mechanical Engineer's Handy Office Companion." By Robert Edwards, C.E. (London: Crosby Lockwood and Son, 1898.) Price 3*s.* 6*d.*

This is doubtless the germ of what will develop into a much larger volume. Mechanical engineering is such a large subject that it is quite impossible to condense matter relating to it within the space afforded by some 60 pages. At the same time, for the workshop and office elaborate sets of tables to the seventh place of decimals are not so much required as plain formulæ and rules that will give results sufficiently accurate for all practical purposes. Mr. Edwards has probably had this idea in view, as the "Office Companion" clearly indicates that it is the work of one who has felt the need of having the means at hand of making calculations rapidly and accurately without the loss of time occasioned by turning over many pages. Thus in the general tables is one of numbers 1 to 100, each number advancing by quarters. Each number represents inches (of course, it may represent other units). Its decimal equivalent in feet and millimetres is given; as the diameter of a circle, the area in feet and in inches of the latter is given, and also the circumference. The weights and measures are all arranged with metrical columns; long measure, for example, has kilometres, metres, and millimetres. A useful electrical table of equivalent kilo-volts, horse-power, volt-ampères, foot-pound minutes and seconds is also given. The rules and tables given for the strength or proportions of machinery are all arranged with suitable factors of safety, &c., from the actual practice of the present day. Formulæ are not stated in algebraical language, but in plain English; this is an advantage which will doubtless be appreciated. A useful rule for the power required to propel moto-vehicles is given; this rule is a modification of the one usually employed, but expressed in terms of brake horse-power per ton. There is much useful information in the book, plainly and clearly expressed. It is just the kind of work for a mechanic to refer to, but the price seems high, especially as compared with similar publications.

La Revue de Méchanique.—The August number contains several articles of great use to the advanced engineering student. That by Professor Dwelshauvers-Dery upon the "Compression of Steam in the Clearance Spaces of an Engine" is, it is needless to say as coming from this distinguished authority, a critical study of the highest order and importance. It is divided into six chapters and contains an exhaustive analysis and discussion of the effect of steam compression under various conditions. M. Rateau continues his investigation of the "Theory and Application of Turbines," and in the present number he discusses, among others, the Pelton wheel, of which he gives the complete theory. M. C. Roche continues his description of various types of French warship machinery, the machinery now described being that of the "Amiral Trehouart," "Jemapes," and "Valmy." There is also an excellent description of various systems of "Grain Elevators," by M. G. Richard, and much other interesting matter. The number is, as usual, well illustrated.

Cassier's Magazine.—The September number is mainly devoted to mining and naval matters. As regards the former there is a copious article on "Diamond Mining in South Africa," by Mr. T. H. Leggett, and one on "The Cyanide Process," by Dr. Joseph Richards. Captain Zalinski describes the use of "Torpedo Guns Afloat and Ashore," with special reference to the part the "Vesuvius" took in the bombardment of Santiago. We doubt whether the author's views on the value of this weapon will find general acceptance. "Speed as an Element of Warship Design," by Mr. M. McFarland, U.S.N., is a not very logical demonstration of an accepted principle. "The Protection of British Commerce in War Time," by Lord Charles Beresford, is an inconclusive thing in the nature of a pot-boiler in that officer's well-known style. As a contribution to naval science it is utterly valueless. It is followed by an excellent and instructive article on "Projectiles for Modern Naval Ordnance," by Professor P. Alger, U.S.N. Needless to say a projectile making its way through a nickel steel armour plate is a most unquestioned automotor, whose speed even the most conscientious policeman would have some difficulty in measuring. An interesting and amusing account of the latest big American swindle is given. This it seems took the form of a scheme for extracting gold from sea water. It appears that the "inventor" and manager built a small shed at the end of a wharf projecting into the sea. Through a hole in the floor there was lowered, by means of a windlass, a large box containing a pan of mercury. An electric battery, supplied by the "inventor," was applied during a whole night in the presence of some capitalists from Middletown, Conn., who had brought with them the mercury. The next morning the mercury was lifted from the water and given to a chemist, who assayed it, and found in it 4.50 dollars of gold, and thereupon the capitalists, much pleased, paid the first instalment on their investment. The deception in the experiment, according to the detective, consisted in a diver's proceeding under water during the night to the box, pouring out the mercury, and substituting for it another lot of mercury containing gold. Upon this basis was floated the 10,000,000 dollar company. Its success in obtaining gold at North Lubec was attested by its sending frequently to the New York Assay Office "gold bricks" containing each about 2,000 dollars of gold, and the exhibition of similar bricks at the Company's office in Boston. Now comes the news that the whole thing has collapsed, and that the "inventor" of the process and manager of the Company—the Electrolytic Marine Salts Company, of North Lubec, Me.—has absconded after having received the snug sum of 338,000 dollars, or about £67,600, of the "profits," which were derived not from sea water, but from the stockholders. According to a recent news paragraph he sailed for Europe under an assumed name after having converted about 100,000 dollars cash into Government bonds in New York City. The "gold from sea water" scheme thus appears to have been one of the most gigantic swindles of recent years. It was similar in many respects to the Electric Sugar Refining swindle in New York City in 1884, by which many prominent business men, including even sugar refiners, were victimised.

The Engineering Magazine for September is more than usually good. Vice-Admiral Colomb contributes an able article on "The Essential Elements of Modern Sea Power." The late Spanish-American War continues to be the subject of investigation at the hands of various writers. This time it is Mr. Hiram S. Maxim, the well-known automobilist, who thinks that the lesson taught by the war is that mechanical supremacy is the vital factor in naval success—a conclusion that we share with him. It is the man who can use the machine that wins. The Spanish, as Mr. Maxim shows, had the tools and machines, but, like the Chinese, they allowed them to get out of repair, and besides were without the mechanical instinct. The consequences in both cases were obvious. A very interesting article is that by Mr. Greslar Lindenthal, on "European and American Bridge Construction." "The Comparative Cost of Steam and Water Power" is discussed by Mr. W. Webber. The article which we think will be most widely appreciated is that on the "Underground Railways of London." Few people have any accurate idea of the cost of the Metropolitan and District Railway. Some of the more recently-built portions, such as the Mansion House and Aldgate section has cost £372,000 per mile. We are told that the capacity of the lines is about 15,000 persons per hour; a complete circuit of the line is made in 70 minutes, and the average speed is 14 miles per hour. The account of the tubular railways is no less interesting. Mr. J. Sinclair Fairfax discourses learnedly on some comparative points of international patent law. Nowadays nearly everyone has occasion to have some connection with the "inventor," usually a plausible, generally clever, but invariably a more or less impecunious individual, and once one touches "patents" it is difficult to say what the result will be; it may be fortunate, but the possibility is that it will not, and when one attempts to patent an invention abroad the process is tedious and expensive, and the would-be patentee has little guarantee that his patent is after all valid. Mr. Fairfax gives inventors some very useful information, and his advice should be the means of saving them a good many pounds. Just now petroleum is one of the subjects occupying the attention of the public, and every information as to its production is of value. Mr. D. A. Louis describes the Baku petroleum district of Russia in a most graphic manner. His article abounds in information and is well worth reading. Electric traction by means of alternating currents is the second contribution to this important matter by Messrs. Chas. Davis and H. C. Forbes. Tramway and railway engineers will peruse it with advantage.

The Automotor and Horseless Vehicle Pocket-Book, &c., for 1898, contains over 200 pages of information. Price 1*s.*; post free, 1*s.* 2*d.*; leather, 1*s.* 8*d.*, of F. King & Co., 62, St. Martin's Lane, London, W.C. See it for reprint of the "Locomotives on Highways Act, 1896."

THE DUPLEX MOTOR.

This is a spirit or light-oil motor working on the Beau de Rochas cycle, but the peculiarity in the design is that it is double-acting, there being an impulse on the piston in each revolution. For the impetus given by the first, will sensibly lessen the rhythm of the vibration caused by explosions taking place at intervals of one-tenth of a second, and acting always in like manner in the ordinary motors such as Daimler's or others, even with two cylinders.

In establishing a symmetrical type of this motor, it remains only to place the other parts and a cylinder, so that they bolt together sideways to obtain a motor with two cylinders, and by making the

Fig. 1.

Fig. 2.

following description we are indebted to our contemporary, *La France Automobile*:—

This motor, although it has only one cylinder, affords greater means for lessening unpleasant vibrations than other motors, by reason of the two explosions taking place in one revolution and in a contrary direction, so that the second explosion coming (at 600 turns per minute) at one-twentieth of a second reacting against the shaft with cranks set at 180°, an explosion will be produced at each stroke of the pistons with the parts perfectly balanced, and consequently there will be no vibration.

Description (*see* Figs. 1 and 2).—The motor is composed of a cylinder, 1, in which the piston, 2, works; the piston rod, 3, is attached to the crosshead, 4, which through the connecting rod, 5, communicates the movement to the cranked shaft, 6. Upon this shaft, 6, is keyed a helical gear, 9, engaging with another, 10; this last, having twice as many teeth as the former, causes the main shaft to turn, 11, one revolution to two against the crank shaft. The admission of the explosive charge is effected by the pipe, 20, and the automatic valve, 21.

The carburated air passes through pipe, 24, to valve, 25, open for this purpose, and fills the space, M, at the back of the piston during its forward motion. The valve, 25, remains open until the piston has completed half of its backward motion, also the valve, 26, so that half of the explosive mixture returning again through pipe, 24, passes from the M side of the cylinder to the other side, N. At this half of the stroke the two valves close; the half volume in M is compressed there, then fixed by the electric spark of the igniter, M, and the resulting explosion starts the piston; this during its forward motion compresses the other half volume in N, where it is then fixed by the spark of the igniter, N, and makes the second explosion, sending back the piston; the valve, 27, allows the first burnt particles to escape, then the same operation is done the other side by the valve, 28. In 19 and 29 are the commutators distributing alternately the currents to the igniters (M and N).

As will be seen, all the motion rods, crank, &c., are closed in, but are easily accessible for examination, &c.

The above motor is 145 mm. × 120 mm. stroke = (5·708″ × 4·724″). It has a fly-wheel weighing 110 lbs., and runs at 600 revs. per minute; it gives off 6 H.P., and weighs 400 lbs.

THE CROCKER-WHEELER SLOW-SPEED MOTOR.

THE 2 H.P. slow-speed motor runs at 100 revs., and has eight poles and eight brushes. The brush-spindles are connected to two rings, the positive brushes to one and the negative to the other. These rings are rigidly connected, but insulated from one another. The rings are placed next to the armature, leaving the commutator clear and easy of access. There is a characteristic of slow-speed motors which in certain cases gives them an important advantage over others. Their moment of inertia is low and permits starting from rest in a minimum of time with a minimum of current. In the case of the above 2 H.P. 100 revs. armature, the product of the moment of inertia by half the square of the angular velocity is 280 foot-pounds, while in the case of the 2 H.P. 1,000 revs. motor it is 900 foot-pounds. Where the duty the motors have to perform requires quick and frequent starting and stopping this difference is very noticeable, and plays an important part in the economy of the plant. The regulation, however, is much less perfect with slow-speed motors. A 5 H.P. motor at 950 revs. will slow down 4 per cent. when full load is put on, but a 4 H.P. motor at 200 revs. will slow down 15 per cent. under the same conditions. In shunt motors the field is controlled by a rheostat or is wound in multiple sections, whose circuits are opened successively. Series motors have their speed controlled by short-circuiting various portions of the field. Compound motors have a constantly excited shunt and a series field in two sections, or they have an unvaried series-coil with a shunt-coil whose strength is changed by a field regulator. All these motors are designed to be capable of an increase of 50 per cent. above normal, and a decrease of 10 per cent. below normal speed. Two kinds of controllers are used; the cylinder reverses giving as many speeds backwards as forwards, operating through a resistance, regulating the speed by cutting down the voltage supplied by the line, and a commuter, specially designed for use with a compound motor. The commuter varies the speed by changing the connections of the various field-coils.—*Electrical Engineer*, New York.

DÜRR'S PETROLEUM BURNER.

IN this method of burning petroleum, invented by Herr Dürr, the well-known engineer of Bremen, there are two burners and one vaporising chamber—one burner being used to heat the latter and so vaporise the oil, while the other acts as the burner proper, *i.e.*, it performs the function for which the apparatus is intended. These burners are placed the latter above the former with the vaporising chamber between them. The construction is shown in the following drawings in which Fig. 1 is a longitudinal section and Fig. 2 a cross section:—

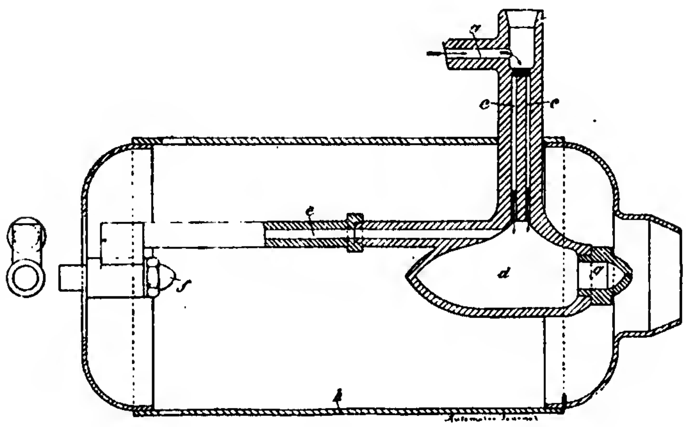

FIG. 1.

The vaporiser body, in which the petroleum gas or vapour is produced, consists of a hollow body, *d*, which is made in one piece of suitable cast iron; the vaporiser, *d*, is provided with a tubular piece, by means of which it is connected with the pipe, *a*, for

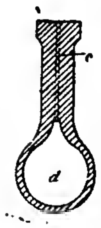

FIG. 2.

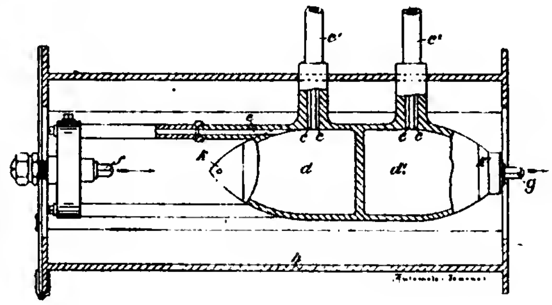

FIG. 3.

supplying the petroleum which enters the vaporiser from the supply pipe, *a*, through fine perforations, *c*, in the tubular piece; for regulating the supply of oil there is inserted into the upper part of the tubular piece a valve, *b*. This valve is accessible from above; for cleaning it is easily removed and a cleaning device is then forced through the perforations, *c*. In the upper point of the vaporiser the

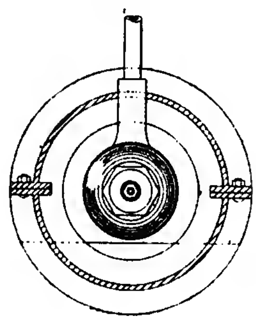

FIG. 4.

illuminating or heating burner, *g*, is inserted; from the lower side of the vaporiser a tubular piece, *e*, leads to the heating burner, *f*, which is mounted at the bottom or inner end of the casing, *h*, where it is capable of being easily examined.

The petroleum enters, in a regulated but sufficient quantity, slowly into the vaporising space. For putting the apparatus into action the vaporiser is first heated by a burning wad of cotton-waste or the like placed around the same. Petroleum vapour passes through the pipe, *e*, to the heating burner, and ignites in front thereof, and the heating flame thus produced spreads over the vaporising body, heating the latter, so that the petroleum is transformed into superheated gas or vapour. This complete gasification or vaporisation has also the result that deposits are not formed in the vaporising space.

The vaporiser, *d*, may be of any suitable shape, but in order to utilise the heating flame as much as possible it is, however, advisable to give it such a shape that the heating will spread over it on all sides; for this reason the ellipsoidal form shown is preferred. The form of the front burner, *g*, depends on whether it is to be used for heating or for illuminating. After this burner has been screwed out the vaporising space can be easily examined.

Figs. 3 and 4 show a second construction of the vapour burner in longitudinal section and in front elevation respectively. In order to prevent the vaporiser from cooling quickly, should the working be interrupted, it is divided, so that the two burners, *f* and *g*, have separate vaporising chambers, *d* and d^1 respectively, each of which is provided with a separate petroleum supply-pipe, c^1 or c^2. The feeding and arrangement of these supply-pipes correspond to those of the construction shown in Fig. 1.

When the petroleum supply of the pipe, c^2, for the illuminating or heating burner, *g*, is shut off, the lower half of the vaporiser and its appurtenances continue to work, so that the heating burner is fed with gas or vapour as before, and it heats the vaporiser so perfectly that, when the petroleum supply to the vaporising chamber, d^1, is reopened, the illuminating burner, *g*, enters at once in action. In this construction the vaporiser is provided at each end with a removable closure-head, *k* or k^1.

Dorey's Carburettor.—A successful form of carburettor is that known as Dorey's, for which many practical advantages are claimed. This carburettor was shown in action at the recent Automobile Exhibition in Paris, where it attracted considerable attention. As will be seen by the accompanying illustration, it consists essentially of a reservoir, B, into which the oil flows through the inlet, A, as the float, C, descends. This float, C, has a small point at the top, which regulates the flow of the oil in proportion as the oil is drawn towards the motor by suction; the feed of the oil is thus regulated automatically by the speed of the motor. When the motor is in work it draws the oil through the channel, E, up to F, and here meets with a strong current of air drawn in through the orifice, G, likewise by the suction of the motor. The oil is broken up by the rush of air, and is in this state sent through the fans, H, which run at a high speed. These turbines complete the admixture of air and oil, and a perfect gas is sent to the motor. The working is very simple, and the advantages of this carburettor are that the motor can be set to work at once, and there is marked economy in the quantity of oil used, and no smell, as every drop of the oil is turned into gas.

Gear Chains.—We have always urged that the various chains for cycles and moto-vehicles introduced during the last few years possessed no mechanical advantages over the plain plate link while being much more expensive. A chain much boomed when it came out was the Simpson Lever Chain. Cyclists swore by it, as they do by every novelty which is based upon the inversion of some mechanical principle. We were consulted about the application of this chain to certain moto-vehicles, and after due examination we reported that there was no mechanical advantage in fitting it. The Company has lately been wound up; the proprietors having found that the chain was useless as an invention, and so ceased to make it.

OBITUARY.

DR. JOHN HOPKINSON, F.R.S.

THE tragically sudden and simultaneous deaths of this distinguished engineer and three members of his family (two daughters and a son) have produced a profound shock in engineering and scientific circles. Dr. Hopkinson and his family were taking their holiday in Switzerland. Being expert mountaineers, he, together with his son and two daughters, attempted on the 27th ult. to climb a peak in the Alps known as the Petite Dent de Vesivi. All the party were tied together by a rope, as is customary. Unfortunately, they slipped and fell over a steep cliff, at the foot of which their dead bodies were discovered the next morning.

Dr. John Hopkinson was a man of very rare talent and ability. He came of a well-known and successful—both commercially and intellectually—Manchester family, and was thus enabled to pursue the natural bent of his mind under the most fortunate auspices, and with none of those hindrances to success that most people experience. He was born in 1849, and at 22 years of age was a Senior Wrangler and Smith Prizeman. He was also an M.A., Whitworth Scholar, and D.Sc. In 1872 he became consulting engineer to the well-known firm of Messrs. Chance Brothers, of Birmingham, and was chiefly engaged in lighthouse work. In this branch of engineering he effected many improvements, and invented the now widely-used system of "group flashing." Many of the most powerful lights on our own and foreign coasts were designed by him. His great work, however, was the giving to the world the complete theory of dynamo design. Of course, dynamos were used long before this, but their construction was entirely a matter of rule of thumb and empiricism. Dr. Hopkinson showed how for any stated output every part in a dynamo is a matter of calculation. The result of his researches was that the practice of dynamo and electromotor design was entirely revolutionised, and the perfection and high efficiency of these machines as now made are due entirely to him. The credit for the introduction of electricity for lighting and traction purposes, especially by municipal bodies, must also be accorded to him, and his success in this direction, as in other fields of engineering, was the conscientious application of the principle that physical research and calculation should always precede practical application. This is the rock upon which not a few engineers split. So-called "practical experience" is too often relied upon rather than scientific research, with disastrous results.

Dr. Hopkinson's career was a striking instance of the supreme importance and great value of a sound mathematical training to an engineer. Had he commenced his career by going as a pupil to an engineer in practice, or had he gone through the "shops" in the orthodox way, he would have remained a comparatively unknown man. As it was, he became a Senior Wrangler before he became a pupil, and hence as a young man could tackle the most abstruse engineering problems with a facility and certainty that older engineers would have shrunk from or would have solved by a trial and error process. Dr. Hopkinson was in every way an example to be copied. By his death we lose not only one of the few really distinguished engineers of the day, but also a perfect gentleman, using that word in its truest sense.

THE EARL OF WINCHILSEA.

THE Earl of Winchilsea died on the 7th inst. at Haverholme Priory, near Sleaford, in the presence of his family, after a long illness.

His lordship, who is succeeded by the Hon. Henry Stormont Finch-Hatton, was born in 1851. Lord Winchilsea in 1892 established the National Agricultural Union, with the object of uniting agriculturists and to induce them to co-operate in all matters of mutual interest. In season and out of season his lordship preached co-operation as applied to agriculturists, and in his newspaper, the *Cable*, he wrote article after article driving home the same truth. In politics he was a Conservative, and represented South Lincolnshire from 1884 to 1887. His estates included about 12,900 acres.

In recent days the Earl of Winchilsea came more prominently before the public eye by reason of his association with Mr. Harry J. Lawson and Mr. Hooley.

DOINGS OF PUBLIC COMPANIES.

Mr. H. F. Pollock, M.P., has been appointed chairman of the European Petroleum Company, from the Board of which Lord Clanmorris and Lord Granby lately resigned.

London General Omnibus Company.

The ordinary general meeting of the London General Omnibus Company (Limited) was held on the 18th ult. at the offices, 6, Finsbury Square, Mr. John Pound presiding. The Chairman, in moving the adoption of the report, said the receipts during the past half year were £553,223 and the expenses £512,195, the profit on working being £41,028, as against £59,717 in the corresponding six months of the Jubilee year. They had run 90 more omnibuses and 1,000,000 additional miles, and carried 6,250,000 more passengers, but the receipts showed an increase of only £13,785, or a decrease of 2*s.* 9¾*d.* per omnibus per day, making a difference in the half year of nearly £20,000, and more than accounting for the variation in profits. With regard to the expenses, although they had been increased by £32,474, they were proportionately rather less than those of last year. The price of provender had been rather adverse, but this excess had been neutralised by economies in other directions. The horse stock had been well maintained, and the average life had exceeded that of the corresponding period of the previous year. As to steam omnibuses (even supposing a company were in the position to put them on the road), the directors considered that they could not compete successfully with omnibuses drawn by horses. The Board proposed to carry £10,000 to the reserve, making it £175,000, and to declare a dividend at the rate of 8 per cent. per annum and a bonus of £1 5*s.* per cent. (equal to 10¼ per cent.). The motion having been seconded, the resolution was agreed to. Mr. Horton moved a resolution authorising the directors in future to abstain from putting in the report the price paid by them for provender. He considered that it militated against them, and was not in the best interests of the Company. Mr. Costello seconded the proposition. A shareholder opposed the motion, and objected to the directors being invested with this further power. After a little disorderly discussion, and the Chairman having expressed the opinion that the suggestion was in the interests of the shareholders, the resolution was put and carried by a small majority.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

Compound Hydro-carbon Motor Syndicate (Limited).—Registered by Budd and Co., 24, Austinfriars, E.C. Capital £12,000, in £1 shares. Object, to enter into an agreement with John Holroyd, Edmund Wiseman, and C. T. Wordsworth, for the acquisition of the business carried on by them at Luton, Bedfordshire, and to manufacture, sell, and deal in oil, gas, steam, and electric motors, moto-cars, and cycles of all kinds. The first directors are J. Holroyd, E. Wiseman, and J. Tearle.

Farley Cartman Company (Limited).—Capital £20,000, in £1 shares. Objects, to enter into an agreement with Cecil O. Webb, and to manufacture, repair, and deal in machinery, engines, boilers, electric plant, electric light, electricity for traction, motive, and other purposes, automotor cars, carriages, vans, vehicles, &c. Registered by B. Webb, 16, St. Helen's Place, E.C.

Jackson and Harrison (Limited).—Capital £3,000, in £5 shares. Objects, to acquire the business carried on by George H. Jackson and William C. Harrison, at 132, Woodhouse Lane, 120, North Street, and "Bon Marche," New Briggate, all in the city of Leeds, and to carry on the business of cabinet makers, decorators, cycle and moto-car manufacturers, electrical and general engineers, &c. The first directors are Henry R. Webster (Chairman), Benjamin Mountain, Richard R. France, George H. Jackson, and William C. Harrison.

Liverpool and District Cycle Trades Association (Limited).—Registered by T. T. Hall, 22, Chancery Lane. Capital £1,000, in £1 shares. Object, to promote and protect the interests of cycle, motor, and carriage manufacturers; to hold and subsidise in Liverpool or elsewhere shows for the exhibition of cycles, &c.

Liverpool Cycle and Motor Show (Limited).—Registered by Halse, Trustram, and Co., 61, Cheapside, E.C. Capital £1,000, in £1 shares. Object, to carry on business in the manner suggested by the title. The first directors are J. C. Robinson, R. MacLennan, C. Coops, C. Hughes, N. Maclumpha, and H. Robinson.

Martini Ozone Company (Limited).—Capital £10,000, in £1 shares. Objects, to acquire the patent rights in any inventions for improving vacuum dielectrics, electrodes, and apparatus for the production of and utilisation of ozone, to enter into an agreement with Dan Martini, and to carry on the business of electrical and mechanical engineers, cycle and moto-car manufacturers, &c. The first directors are Dan Martini and John Dunham-Massey. Registered office, 8, Princes Street, E.C.

Motor and Cycle Trades Club (Limited).—Registered by Jordan and Sons (Limited), 120, Chancery Lane, W.C. Capital £1,000, in £5 shares. Object sufficiently indicated by the title. President, Charles Showell, Esq. The property and control of the Club is vested in a general committee. Registered office, 26, Corporation Street, Birmingham.

Motor Touring Company (Limited).—Registered by A. H. Atkins (Limited), Bouverie Street, E.C. Capital £5,000, in £1 shares. Object, to adopt a certain agreement, and to carry on business as motor car, coach, and cab proprietors, carriers of passengers and goods, motor car and coach builders, &c.

Recreation Motor Cars (Limited).—Registered by T. Scott, Devonshire Chambers, Bishopsgate Street Without. Capital £10,000, in £1 shares. Objects, to enter into an agreement with Henry Johnson, and to manufacture, sell, let out on hire, export, import, and deal in moto-cars of every description. The first directors are: Wm. M. Gow, Arthur Eliot, and Henry Johnson.

Société Internationale de Construction d'Automobiles (Limited).—Registered by G. St. G. D. Massey, 8, Princes Street, London. Capital £50,000, in 5,000 £1 shares and 11,250 £4 shares. Object, to acquire either solely or jointly with other persons or companies, in France and elsewhere, patents, licenses, and other rights and privileges concerning the manufacture, the sale, the exportation, and the importation of motors, motor-carriages, tricycles, and all other accessories relating to the industry of mechanical and electrical engineers, metal founders, wheelwrights, blacksmiths, carriage builders, wood turners, upholsterers, and lamp manufacturers; with a view to the above object, to adopt and carry out, with or without modifications, an agreement dated July 11th, and expressed to be made between Messrs. Tauzon et Cie. of the one part and M. P. E. Moyse, as trustee for and on behalf of this Company, of the other part; and, further, to act as mechanical and electrical engineers, motor manufacturers, carriage builders, painters, &c.; as manufacturers of motors, motor-carriages, bicycles, carriage builders, &c.

White's Carriage Company (Limited).—Registered by Thomas T. Hall, 22, Chancery Lane. Capital £50,000, in £1 shares. Object, to acquire upon the terms of an agreement made between W. White, jun., as vendor, of the one part and this Company of the other part the business of dealers in and importers and exporters of cabs, carriages, cars, and other vehicles, and of horses and other animals, and of motor-cars, motors, and other machinery. The first directors are R. B. Crowe and W. White, jun.

ACCIDENTS AVOIDABLE BY USING MOTO-CARS.

A two-horse brake on the 11th inst. was proceeding down a steep hill at Hawkwell, near Southend, when the horses bolted and the vehicle overturned. Nine of the 11 occupants were injured.

Mrs. Harroby, of West Kensington, on the 12th inst. was being driven to Victoria in a cab, when the horse shied at a bicycle, causing the vehicle to swerve and overturn. Mrs. Harroby was seriously injured and the cabman sustained a fractured arm.

JOY'S VALVE GEAR FOR STEAM MOTO-VEHICLES.

It is well known that the steam-engines used in launches and moto-vehicles are exceedingly extravagant in their steam consumption. In such motors the consumption will be anything from 25 to 30 lbs. of steam per horse-power hour; this not only means that a larger supply of feed-water has to be carried, but also that the fuel consumption in the boiler is unduly great. In these small motors it is usual to have a late cut-off so as to get a high mean pressure, and therefore high engine power, as compared with the size of the cylinder. In these small motors the steam distribution is most usually effected by means of Stephenson's well known eccentric and link-motion gear. This was originally introduced by the celebrated engineer of that name, and was by him applied to locomotives, for which purpose it was at that time eminently well suited. Those were the days when it mattered little how much coal and water were consumed. This gear is still largely used on railways, especially on those roads known as being not too progressive, the reason for its retention being mainly that its fitting and adjustment is well understood by the ordinary journeyman engineer. For this reason it is, as is the old-fashioned Scotch return tube-boiler, almost exclusively employed on vessels of the mercantile marine.

In this gear the motion of the valve is synchronous throughout its stroke, that is, the valve passes over equal spaces in equal times; this means that the ports on the cylinder face are gradually opened and as gradually closed, thus producing wire-drawing on the admission side accompanied by a loss of pressure and undue cushioning on the exhaust side. In both cases power is lost which by the adoption of suitable valve gear might be saved.

Considering how necessary it is to keep down weights in steam moto-vehicles it is somewhat surprising that so far the British constructors of these machines still cling tenaciously to an obsolete and most extravagant form of valve gear, necessitating as it does the carriage of larger fuel and feed tanks (thereby lessening the useful dead weight carrying capacity of the vehicle).

French and German constructors have for the most part abandoned the Stephenson valve gear. Thus Weidknecht uses the Solms (a modified Hackworth gear), and Le Blant the Walschaert gear.

In moto-vehicles in which steam is the propelling agent the importance of a proper steam distribution can hardly be overestimated, as, owing to the inferior evaporative powers of the boiler and the transmission gearing, the absolute efficiency of the machine is extremely low.

In an ordinary steam cylinder, in order to effect a proper steam distribution, the valve motion should be such that directly the crank has passed its dead centre the admission port in the valve opens to steam, and remains *full* open during the period of admission. The port should then close suddenly and remain closed during expansion; it should then suddenly open, and remain full open during the period of exhaust, closing again and suddenly opening during admission. To effect this it is necessary that the valve should in its travel be alternately accelerated and retarded. This constitutes the great defect of the Stevenson gear. Since his time many engineers have endeavoured to accomplish the movement indicated. Corliss practically succeeded in so doing, but his gear is altogether inapplicable to the class of motor we are considering. Hackworth and Marshall in England, Bremme and Walschaert on the Continent, have introduced gears which meet the condition laid down more or less completely. The gear, however, which gives the best steam distribution, and at the same time is simple and inexpensive, is that known as the Joy valve gear.

This gear has been before the engineering public for the last 20 years, and it has been applied with the greatest success to all classes of steam-motors—especially to locomotives warship and launch engines. It is thus by no means a novel or untried invention. We introduce it to the readers of The Automotor, as from our knowledge of its working we think it will solve in a very satisfactory manner one of the most important problems in moto-vehicle design. The principle of the gear is shown in Fig. 1, which represents the connecting and valve rods of a horizontal engine, the former being at the end of its stroke, and the latter, *G*, being practically at rest, but just about to make a sudden movement to the left which constitutes the admission period of the ordinary steam cycle. To the connecting rod at a point, *A*, about one-third or so from the piston-

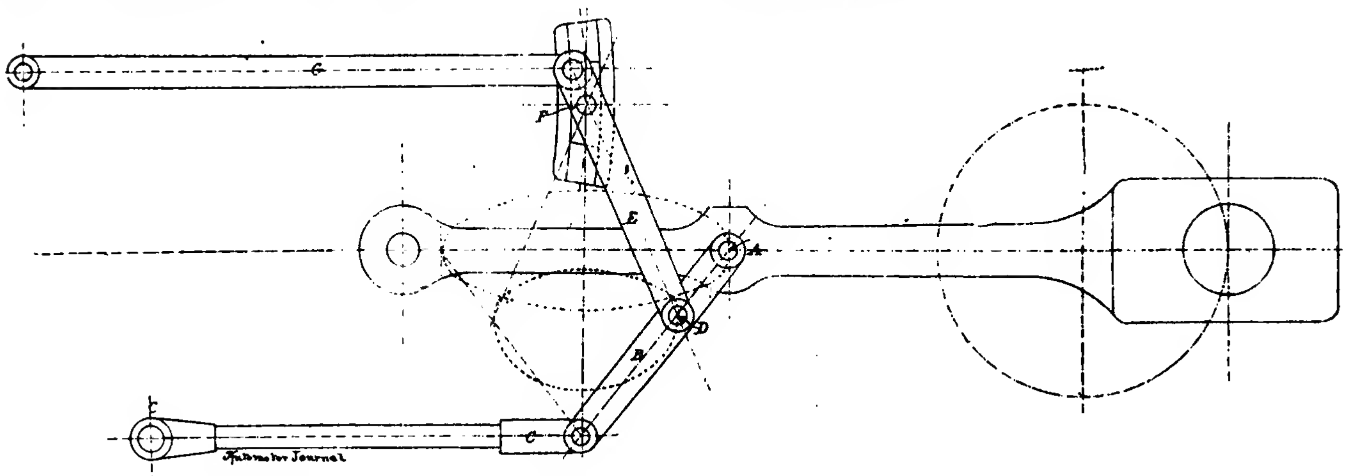

Fig. 1.—Position of Links at End of Stroke.

rod end, is attached one end of the link, *B*; the other end being attached to the end of a simple vibrating link, *C*, the end of which, *C'*, swings on a fixed pin. As every engineering student is aware, the point path described by *A* is an ellipse, hence the path described by a point in the link, *B*, will be the resultant of the elliptical path due to *A*, and the circular arc described by *C*; the result is that the point, *D*, describes a peculiar flattened oval as shown (in dotted line). At *D* is attached the swinging lever link, *E*, which is fulcrumed to a pin, *F*, this pin is held in a slipper which moves in the curved slotted path, *J*, of radius equal to the slide valve connecting rod, *G*, the end of this rod being joined to the link, *E*. The point, *D*, of the link, *E*, during a complete revolution of the crank describes as stated, the flattened oval as shown the other end of *E*, viz., that connected to *G* describes as the fulcrum slides up and down the curved slot, *J*, a vertical ellipse; the proportions of the links are so chosen that the lesser diameter of this ellipse is equal to twice (lap + lead). As shown, the curved slot is in a position at right angles to the axis of the cylinder, this gives the mid-gear position. If now the curved slot, which is also fulcrumed at *F*, be inclined the ellipse described, the end of rod, *G*, where it joins link *E* will be inclined; hence by inclining this slot in either direction, direct and reverse motion is obtained. With this gear the "lap" and "lead" are constant, but the admission is regulated by the position of the curved slot. A little reflection will render it evident that if the lever, *E*, were pinned direct to the connecting rod at the point, *A*, it would vibrate its fulcrum, *F*, unequally on either side of the centre of the curved slide, *J*, by the amount of the versed sine of the arc of the lever, *E*, from *FD*; it is to correct this error that the lever, *E*, is pinned at the point, *D*, to a parallel motion formed by the parts *B* and *C*. The point, *D*, performing a figure as seen equal to an ellipse, with the error to be eliminated added, so neutralising its effect on the motion of the fulcrum, *F*.

The point, *F*, represents the centre of oscillation for the links and the centre or fulcrum of the lever. And these must coincide, when the piston is at each end of the stroke, the lead being fixed, the links can be pulled over from forward to backward, or any point of expansion, without altering the lead. This may be taken as a test of the gear being set out correctly.

Thus the "lap" and "lead" are opened by the action of the valve-lever acting as a lever, and the port opening or admission is given by the incline of the curved slot in which the centre of that lever slides, and, as before said, the amount of this opening depends upon the inclination of the curved slot. It follows that when these two motions synchronise the travel of the valve is very rapid, and this occurs at admission. Then follows the period in which these two motions are out of phase, or opposed to each other; when this occurs the valve travel is checked and the steam port is then fully open. The next acceleration produces the sharp cut-off, which is such a desirable feature in any steam-engine.

Fig. 2.—End Elevation of Vertical Engines.

Fig. 3.—Side Elevation of Same.

The "compression" resulting with this gear is also reduced to a minimum, owing to the peculiar movement given to the valves (*i.e.*, the series of accelerations and retardations referred to), as while the "lead" is obtained later and quicker, the port is also shut for "compression" later and quicker, doing away with the necessity for a special expansion valve, with its complicated and expensive machinery, and allowing the main valve to be used for expansion, as the "compression" is not of an injurious amount, even with a "cut-off" reduced to 15 per cent., or about one-sixth of the stroke.

So much for the question of steam distribution. As regards the practical fitting of this gear, this is shown in Figs. 2 and 3, which represent a set of vertical three-stage marine engines. The same method of fitting would be followed in engines, whether simple or compound, intended for moto-vehicles. It will be observed that in this gear no eccentrics are employed, and the fitting is altogether much more simple. Both space and weight are saved to a very considerable extent; the latter is, it is needless to say, a point of no mean importance in moto-vehicles, where we are so sadly limited as to weight. G. H. L.

JOURNALISTS ON AUTOMOBILISM.

In the pre Board School days the Press was all powerful. Cabinet Ministers consulted editors, and a "leader" in an influential morning paper was regarded by the common people as a kind of Delphia oracle. In most cases the men who wrote these leaders were but of little better education than those who read them, and such writers would now be deemed but very indifferently educated people. With the general spread of education the power of the Press has declined, because on the ordinary or common newspapers the writers are rarely better educated or better informed than their readers. Hence the growing number of "specialist" newspapers and journals. If anything is calculated to depreciate a newspaper as a property it is the utterance of opinions on matters which the writers have absolutely no knowledge of whatever. The following is an amusing instance of that good all round knowledge of nothing in particular that is characteristic of so many scribes. A person lately wrote to the *Weekly Sun* asking for advice on moto-vehicles. Our contemporary sagely replied:—

"It would be wiser, on the whole, to defer your purchase of a moto-car for the present. We do not know the company you have been in communication with, and have nothing to say against their vehicles, but, unless you are prepared to face the cost of what at best is a doubtful experiment, you had bettor stick to the local job-master yet awhile. If the matter is pressing, get the car on six months' trial, by which time you will be in a position to judge of its suitability to your requirements. If the makers will not grant such reasonable terms, it ought to be sufficient evidence that their confidence in the machine is not particularly strong. It is quite certain the business is not so flourishing that the company can afford to be too independent, if they wish to give you complete satisfaction as well as to get your money."

"Get the car on six months' trial" is distinctly good; "by which time," &c., is, however, better. As a specimen either of drivelling journalism or of unconscious humour, the above "advice" would be hard to beat.

We then have a garrulous scribe writing in the *Referee* an interesting but wearisome account of his holidays. This person has been to Westgate-on-Sea, where there are, it appears, certain moto-vehicles. Says he: "And so ended my holidays, except so far as a visit to Westgate-on-Sea, where the repose of the invalid settlement is murdered by moto-cars, run for and on account of alien speculators. The moto-car, as it is developed for hire, is a cause of danger to most other wayfarers."

It is hopeless to repeat for the benefit of such writers that in Paris, where there are so many moto-vehicles, the silence with which these vehicles proceed is one of the chief causes of complaint against them. Of course, a spirit-motor and its gear when worn are unquestionably noisy, but much less so than a cab. The London police on night duty in residential districts will detect the approach of a hansom half a mile away by the sledge-hammer blows given by the horse on the asphalt. This noise, from a police point of view, is advantageous; but a moto-vehicle is practically noiseless, and it is this quality which tends to make policemen suspicious of moto-vehicles. A little knowledge is, we all know, a dangerous thing, but such knowledge of moto-vehicles as the scribes referred to above possess is worse than dangerous—it is stupid.

HORSE AND MOTO-VEHICLE ACCIDENTS.

Another "Frightful" Accident to a Moto-Vehicle.—"About three o'clock yesterday afternoon," says the *Morning* of the 20th ult., "an exciting scene was witnessed in the neighbourhood of Fleet Street. An electric moto-cab on turning into Whitefriars Street out of Fleet Street could not be stopped, probably on account of the incline. The cab swayed from right to left, and eventually dashed into a coal van standing outside one of the printing establishments. Two newspaper sellers standing near the van had a narrow escape. Fortunately no one was injured, but the cab was damaged."

[The "dashing" may be judged from the fact that beyond a few bruises on the paint the moto-cab showed no sign of damage.—Ed.]

A Singular Accident.—Accidents accompanied by personal injuries or even loss of life or damage to property, occasioned by horses taking fright, are so common that they hardly get recorded in the ordinary Press. The following singular accident was surely worth a line in the local Press, which usually has to fill up its columns with stale sermons and flabby poems, but hardly any papers noticed it. At Morpeth a Mr. Geo. Bainbridge was driving with two friends in a dog-cart to the station, when another dog-cart came dashing down the hill from an opposite direction. The vehicles collided, the shaft of the runaway cart piercing the breast of Mr. Bainbridge's horse. All the occupants of the vehicles were thrown out, and the colliding vehicle was capsized; in turning over it fell upon a passing cyclist. The damage was very great, and the injuries sustained very serious. It appeared that the horse in the colliding vehicle had been frightened by passing two other horses, which in their turn had bolted with their vehicles. And yet there are many people who, with stupid bigotry, would do all they can to prevent the use of vehicles which would be quite free from this kind of accident.

SELF-PROPELLED TRAFFIC ASSOCIATION

(INCORPORATED).

LIVERPOOL AND DISTRICT CENTRE.

Liverpool Heavy Trials.

In reply to many inquiries we have pleasure in stating that we are informed officially that the Judges' Report for these trials will be presented at the opening meeting of the Third Session of the Self-Propelled Traffic Association (Liverpool Centre), to be held in November next.

THE AUTOMOBILE CLUB OF GREAT BRITAIN AND IRELAND

(With which is incorporated the Self-Propelled Traffic Association).

At a recent meeting of the Club Committee it was decided to form a "Foreign Relations Committee," chiefly for the purpose of arranging reciprocal relations with the Continental Automobile Clubs. Amongst the members invited to sit on this Committee (which has power to add to its numbers) are:—Mr. Roger Wallace, Q.C., Mr. Frederick R. Simms, Mr. Andrew Barr, Mr. Worby Beaumont, Mr. Frank Butler, Capt. the Hon. Cecil Duncombe, Mr. Boverton Redwood, Sir David Salomons, Bart., Mr. Alexander Siemens, Mr. Paris Singer, Rt. Hon. Lord Suffield, K.C.B., Rt. Hon. Viscount Templetown, and the Secretary (*ex-officio*).

The Secretary of the Automobile Club asks us to state that the account of the Club run to Mr. Butler's house-boat on July 23rd should have stated that Mr. Alfred Ledger, with Mrs. and Miss Ledger, were present, having driven in Mr. Ledger's car from Blackheath to Shiplake, a distance of 55 miles.

LAW REPORTS.

Bankruptcy Court.

Mr. Frederick Henry Pollexfen, 13, King William Street, E.C., has been appointed liquidator of the Salocin Patent Carriage Wheel Company (Limited), 64, Finsbury Circus Buildings, E.C.

Cycle and Motor Accessories (Limited).—Under a winding-up order recently made against this Company the statutory meetings of creditors and contributories were held, on the 3rd inst., at the offices of the Board of Trade, Lincoln's Inn Fields. Mr. A. S. Cully, Assistant Official Receiver, presided. The Chairman reported that, according to the articles of association, which were of a very wide nature, the Company was formed to acquire inventions generally, and especially to take over and develop a patent electric cycle lamp. With the exception of Mr. Richards, all the directors paid cash for the shares they acquired, but it appeared that Mr. Richards received 600 shares as nominee of the vendor "in consideration of services to be rendered to the Company." It was understood that he was to introduce or "influence" a certain amount of capital, but this had not been done, and it would be a question for the liquidator to ascertain what liability was upon Mr. Richards in respect of those 600 vendor's shares. It appeared that the Company was promoted by Mr. J. E. Preston and Mr. C. Simkin, each of whom had a half interest in the invention. The purchase price to be paid by the Company was £7,000 in cash and fully-paid shares of the Company. He (the Chairman) did not know upon what basis the patent was valued, but it had not been developed, and it had been admitted that the price was fixed to allow a bonus of shares to be given to intending subscribers. The Chairman added that the Company had only a small amount of debts, and its only tangible asset was the uncalled capital. There was the patent of the cycle lamp, but he understood that a patent agent had a lien on it for his fees, and there was also the question of Mr. Richards's liability upon the 600 shares. No prospectus had been issued to the public, and the money which had been subscribed by the directors had been absorbed in general expenses, payment of the managing director's salary, and the fees of the other directors. The proceedings resulted in resolutions being passed at hoth meetings appointing Mr. Hollis, chartered accountant, liquidator of the Company, with the aid of a committee of inspection.

Leather-Shod Wheel Company.—The case of Howard *v.* the Leather-Shod Wheel Company (Limited) and others came before Mr. Jnstice Phillimore in the Vacation Court on the 7th inst., on a motion for the appointment of a receiver and manager. Mr. Chitty said this was a debenture-holder's action, the plaintiff holding 60 out of 200 debentures of £100 each. He understood that the Company did not appear. Mr. Jnstice Phillimore: This is a case where there has heen a petition presented for winding up the Company. Mr. Chitty: Yes. The debentures are due. There is a trust deed covering the debentures, and I understand I can appear for the trustees. The Company has practically oeased to carry on its business, and the danger is that the Company will deal with its property in such a manner as will materially injure the rights of the debenture-holders. Mr. Justice Phillimore appointed Mr. Arthur E. Howard, accountant, receiver and manager.

Police Court Proceedings.

An Injudioious Jehu.—On August 23rd at the City of London Summons Court, Francis Leadon, in the employment of Arthur Sanderson, of 52, Berners Street, Oxford Street, W., was summoned under the Light Locomotives on Highways Act for causing an obstruction with a moto-van. P.C. Sharplin, 613, said at 5.50 p.m. on the 16th ult. the defendant came to him by the Mansion House and said be had a motor down Walbrook, and he could not get out as a van was in the way. The witness went into Walbrook, a narrow thoroughfare, with room for one line of traffic only, and found the defendant had entered from the south and prevented four vans that had entered from the north end from going through. He told the defendant it was the rule to only enter Walbrook from the north end, so he must back out. After some talk he started working a pipe, remarking, "We have to do this for three minutes before we can start." (Laughter.) A crowd had oollected and the remark caused much laughter. The defendant then took hold of a screw and began moving that, stating, "We have to do this for two minutes." (Laughter.) The crowd was blocking up tbo way by that time, and the defendant next took hold of a handle and began working that, saying, "We have to do this for one minute." (Renewed laughter.) He tben backed slowly out to the Cannon Street end, and refused to go away. He took him to the station. Alderman Strong: Three, two, and one, that would be six minutes. Mr. Richards (the clerk): But did he stop all that time? Sharplin: It was ten minutes before he moved. The defendant said another constable directed him to go through Walbrook. He had no idea of only being supposed to enter by the north end. As to the delay there was no unnecessary stopping. It was a Daimler motor, and he had to pump the pressure into the tubes before he could back, which he did slowly, so as to avoid danger to the publio. A witness corroborated. Alderman Strong said it was quite clear that however the defendant came into Walbrook (and he might be reasonably excused for not knowing of any regulation about which end he should eutor), it was his duty to move out when requested to by the policeman as quickly as possible. He did not believe he did so, and imposed a fine of 10*s.* and costs, reminding him that the full penalty was £10.

Furious Driving.—At the Gainsborough Petty Sessions on the 16th ult., Johu Heinle, pork butcher, Gainsborougb, was summoned for three offences against "the General Order of tbe Local Government Board prescribing regulations as to light locomotives." Tbe offences were against Articles IV, Sections 1, 7, and 8 respectively. The charges, briefly stated, were that he drove a moto-vehicle at a speed greater than was reasonable and proper, so as to endanger the life and limb of one James Hawkins; tbat he did not, at the roquest of Hawkins, a person having charge of a restive horse, cause the said light locomotive to stop and to remain stationary; and that he did not, hy sounding a bell or other instrument, give audible and sufficient warning of the approach of the said locomotive. According to the evidence, Hawkins was a coachman in the employ of Mr. Edward Pearson, J.P., C.C., Morton House, and on June 3rd he was taking a pony trap along Morton Terrace to fetch Mr. Pearson from the office. Near the Elm Cottage there is a dangerous double corner, a sort of Z-shaped hend. On nearing the Elm Cottage, the pony showed signs of terror, when, withont any notice, the defendant's moto-vehicle appeared round the corner, coming at a high speed, stated to be about 10 miles an hour, towards the pony trap. The pony shied on to the footpath, threw itself down, and the driver, Hawkins, was pitched out of the trap. Evidence was given at considerable length on both sides. The Bench deoided that there must be a conviction, hoth for driving the vehicle too quickly, and also for failing to give audible notice of its approach. The chairman explained the magistrates' views at great length, and said the fact of an accident having occurred showed to his mind that proper precautions had not been taken. This being the first case under the Local Government Board Order, the fine imposed would be very small. For fast driving the fine was 10*s.*, 16*s.* 9*d.* costs, and £1 10*s.* solicitor's fee; for not audibly sounding the bell the fine was also 10*s.*, the costs being 12*s.* 3*d.* The total amount was £3 10*s.*

Furious Driving.—At the West London Police Court, on 29th ult., George Deadman was summoned for driving a moto-vehicle furiously, on August 16tb, in Lillie Road, Fulbam. Police constable 485 T said he put up his hand for the defendant to stop, but he went on round the corner and collided with the kerb on the wrong side. The constable described the speed at the rate of 10 miles an hour. The defendant told the magistrate he was only on the tbird speed, which was at the rate of eight miles an hour. He also said the fourth speed was 12 miles, which was the highest it could go. The constable: He said he could go round any corner at eight miles an hour. It was a dangerous corner. The defendant: I cleared the kerb and everything. Mr. Lane, Q.C., inflicted a penalty of 8*s.*, with 2*s.* costs.

The Determination of Speed.—At the Newbury Petty Sessions, on the 9th inst., the Earl of Carnarvon appeared in answer to two adjourned summonses, one of which alleged tbat on August 29th his lordship drove his moto-vehicle on tbe highway at a greater speed than 12 miles per hour, and the other that he did not stop the machine on the signal of Mr. William Walton, who was in charge of a restive horse. Mr. Walton, who is a barrister, residing at Donnington Holt, on the outskirts of the town, and was the complainant, conducted the case in support of the summonses. Mr. George Wallace, barrister, appeared for Lord Carnarvon. The hearing occupied nearly four hours, and the court was crowded, the attendance including several ladies. In support of the two charges, evidence was given by Mr. Walton, Colonel Cunliffe, and others. Mr. Walton stated that on the day in question he was riding on horseback in the Wash Road, when he saw a moto-car coming down the hill, making a great noise. He put up his haud to stop it, but no notice was takon of the signal, and the car travelled down the hill at an increased rate. He timed it by his watch after it had passed him, and subsequently found that it oovered 480 yards in 45 seconds, which was at the rate of 22 miles an hour. He was nearly unseated from his horse, which was much frightened by the noise of the motor. On inquiry, he found that the occupants of the car were Lord Carnarvon and a French engineer in his lordship's service. Colonel Cunliffe estimated that the car was proceeding at the rate of 12 or 15 miles an hour. Another witness estimated that the rate was 20 miles an hour. For the defence Mr. Wallace called Lord Carnarvon's engineer, who gave his evidence in French, which was interpreted by Mr. Crundon, a local resident. The witness said he saw nothing of Mr. Walton or his horse. The moto-car had three brakes, and it could be brought to a standstill in four or five yards. Mr. Anthony G. New, engineer, of Westminster and Woking, gave technical evidence describing the construction of the moto-car, which was of French make. It was worked by petroleum vapour, which was really gas. It was a four-gear machine, and if kept at 600 revs. a minute would be capable of running 12 or 14 miles an bour. It had a governor which prevented its goiug more tban 600 revs. a minute, but if the governor was taken off it would go much faster. The witness said it was extremely difficult to know at what rato a moto-car was going, because people were apt to confuso noise with pace. The faster such a machine travelled the less noise it made. Mr. Wallace, on Lord Carnarvon's behalf, denied that his lordship or his engineer saw any signal given by Mr. Walton. Had Lord Carnarvon seen the signal he would not have been so unneighbourly and ungentlemanly as to decline stopping the machine. The Justices retired to consider the case, and after a short deliberation the Chairman said that the magistrates considered that it had uot been satisfactorily proved that Mr. Walton's signal was seen either by Lord Carnarvon or his engineer, and therefore that summons would be dismissed. As regards the other summons, which alleged that Lord Carnarvon had driven his moto-car at a rate exceeding 12 miles an hour, they had decided to convict, and Lord Carnarvon must pay a penalty of £5 and costs.

Excessive Speed.—At the County Police Court, Birmingham, on the 3rd inst., Alfred Rollason, gentleman, of Winnick Warren, Nottingham, was summoned for driving a moto-vehicle furiously on the Barford Road, on the 12th ult. Police-sergeant Dawson said the car was driven at the rate of 20 or 25 miles an hour. William Canning, farmer, of Debden, said his pony, which was usually quiet when moto-cars were driven past it, was so frightened on this occasion that it backed the trap into a hedge and threw him out. Another witness named Thomas Page gave corroborative evidence. Defendant admitted that he had travelled nearly 30 miles in about an hour and a half. The Bench fined defendant £5 and £1 0s. 6d. costs.

Excessive Speed.—At Northampton, on the 7th inst., Joseph Grose, stated to be a well-known cycle and moto-car manufacturer of London and Northampton, was summoned for driving a moto-car through the streets of the town at a greater speed than was reasonable. The Chief Constable complained of the high speed at which moto cars were driven about the town. A constable named Goodfellow said he timed the car by his watch. It covered 400 yards in 55 seconds, and ran over a dog, which was nearly killed. The magistrates imposed a fine of 20s., including costs.

Excessive Speed.—At Loughborough Petty Sessions, on August 31st, the Rev. E. Foord-Kelcey, the Vicar of Quorn, was summoned for driving a light locomotive, otherwise a moto-car, at a greater speed than 12 miles an hour, the speed prescribed by the regulations of the Local Government Board, on August 20th. Mr. Kenneth McAlpin (Leicester) appeared for the defendant, and, pleading guilty, expressed regret. The machine had lately been purchased, and defendant was tempted to experiment with it, and he admitted that he was driving faster than the regulation speed. He promised that it should not occur again. A policeman said that on the afternoon in question he saw the defendant going into Mountsorrel down the Cemetery Hill on a moto-tricycle. He was going at 18 or 20 miles an hour, and there were a lot of people and traffic about, defendant dodging in and out like a swallow flying along. The Chairman said it seemed a serious affair, for it might easily have led to very serious consequences. One of the magistrates was nearly run into by this same machine. Mr. Kelcey ought to be more careful and more sensible. This was the first case of the kind, and they would only inflict the comparatively small fine of £2 and costs.

The Hampstead Roads.—Mr. Charles H. Lowe, M. Inst. C.E., F.S.I., surveyor to the Hampstead Vestry, says, in his annual report to that body :—"The condition of the roads in Hampstead is good. The standard of excellence, however, which the cyclist has set up has not been attained, and, with the wear and tear caused by the incessant heavy traffic over the main roads, it is hardly possible for it to be, and to make special provision for bicyclists is impracticable. What it might have been had the machine been known to our forefathers can only be surmised. Probably a carriage-way, two footways, and a cycle track would have formed the ordinary highway, repairable by the inhabitants at large. The nearest approach to the ideal, from the cyclist's point of view, is the wood paved carriageway, and, now that the experimental stage in the use of Jarrah and other similar hard woods has been passed, the only thing standing in the way of their more general adoption for paving purposes is the initial cost. The supply of the material is practically unlimited, and, with the cost reduced—and it is reasonable to expect that this will be effected by the competition in the trade—there is no reason why Jarrah should not be used in paving the more important streets, such as are now coated with the best quality broken granite." Referring to moto-vehicles, Mr. Lowe says:—"If ever the day does come which shall see the highways taken possession of by the horseless carriage, that same day will witness the difficulty of maintaining a smooth surface surmounted, for every wheel will have a rubber tyre, and the decrease in the number of horses pounding the roads with their hoofs will be so marked that the destroying agents in the roadway will be reduced to a minimum."

FOREIGN NOTES.

The first electro moto-cab commenced to ply for hire on the streets of Pau on the 9th inst. It is, we understand, a Krieger with Fulmen cells.

M. Scotte has been exhibiting his traction system in the provinces with great success, and much to the satisfaction of local mayors, farmers, and others.

The Mayor of Saint Ouen l'Aumone has issued a bye-law to the effect that moto-vehicles must not exceed a speed of five miles per hour while in his jurisdiction.

A Company has been formed by MM. Fauchère, Ochin, and Dangleterre, with a capital of £6,000, for the purpose of manufacturing the Express moto-vehicle.

The Annual National Exhibition of Work will be held in Paris on October 16th next, at the Palace of Sports, Rue de Berri. A large section will be devoted to moto-vehicles.

There have been a few rather serious accidents with petrol moto-vehicles lately. The vehicle belonging to M. Lucenski was completely burnt near Lisieux through the ignition of the petrol.

Moto-vehicle races promoted by newspaper proprietors are the "correct thing" in France. The latest is one promoted by *Les Sports*, and will take place between Paris and Saint Sebastian.

M. Etienne Giraud, a well-known *chauffeur*, had the misfortune at Mans to run down a child who unhappily was killed. Proceedings were instituted and the Court found extenuating circumstances, but condemned M. Giraud to pay 500 francs and costs.

An experimental electric haulage line is being laid down between Eberswalde and Ragos on the Finow Canal by Messrs. Siemens and Halske, of Berlin. The boats will be hauled by an electric locomotive running on a narrow gauge track on the canal bank.

It looks as though the Paris-St. Petersburg Race will, after all, be abandoned. According to a letter published in *La France Automobile* from a correspondent, it would seem that there are hardly any good roads in Russia. The letter is exceedingly candid on this and other matters. We should think that recent events, too, have rather cooled the enthusiasm of our French friends for "the brave Russians."

A 4 H.P. electro moto-vehicle—the first of its kind—has been introduced into Toronto, Canada, by the Robert Simpson Company. It inaugurates, according to the *Toronto Globe*, the twentieth century movement in that country. We do not know exactly what the twentieth century movement may be, but nevertheless we are glad to learn that, in the words of our contemporary, "it has struck Toronto."

The moto-vehicle, as we have had occasion to remark elsewhere, is not liked by the police, as it is a most effective agent in the hands of the fashionable thief or society fraud. At some of the French seaside resorts the practice is growing up of utilising the moto-vehicle as a means of obtaining access to the better hotels, and, after ransacking the rooms, to depart without paying the landlord for the accommodation. The *modus operandi* is for a couple of well-dressed men to drive up to an hotel in a swaggering style and order lunch or dinner; they propose to stay the night, and retire to wash, &c. After "going through" the rooms and picking up unconsidered trifles of loose cash and jewellery, they have their dinner and go for a drive. They do not return.

The Daimler Manufacturing Company, of America, has acquired all the real estate, personal property, plants, machinery, patent rights, and outstanding accounts of the Daimler Motor Company, Steinway, Long Island, and will continue the business with increased facilities. The officers of the Company are:—Frederick Kuebler, president; Horace Bacon, vice-president; Otto G. Nestle, treasurer and secretary; Adolph O. Krieger, assistant secretary and treasurer.

There is a lull in automobile activity just now in France. Races seem to pall, and with the check that has very properly been given to fast driving, many people have ceased to take much interest in the doings of automobilists. Even the automobile papers seem to find it difficult to say anything fresh. The petrol motor in its unending variants of the single type has been described, re-described, and examined from every possible point of view. It has been put into every conceivable kind of vehicle, from a bath chair to an omnibus, and now we know all about it and for our part do not think much of it. Our contemporaries seem gravelled for lack of matter. With us in The Automotor, we find it a matter of extreme difficulty to keep our numbers within those limits fixed by an unphilosophical and unsympathetic Post Office. We are, in fact, simply bursting with information that we are anxious to impart to our readers.

There is to be an exhibition of moto-vehicles and appliances at Boston, U.S.A., from October 10th next to December 3rd. It will be held, according to the *Horseless Age*, under the auspices of the Massachusetts Charitable Mechanics' Association, at their magnificent building on Huntington Avenue. The forthcoming exhibition will be the twentieth, and will no doubt be even more successful than previous enterprises of the Association's undertaking. More than 2,000 square feet of space have been set apart in the basement for the moto-carriages, and no charge has been made for space. Vehicles will be divided into three classes—steam, hydrocarbon, and electric. Free current will be given electric exhibitors to the extent of a 10 mile run each day, while steam and gasolene motor exhibitors will find fuel and supplies ready to hand. Huntington Avenue, a fine asphalted boulevard, will be easy of access at any time for trial or exhibition runs.

Prospects for the moto-vehicle are, says our contemporary, very bright in Boston and vicinity. The roads in that section are as fine as any in the world, the suburbs of the New England metropolis are unsurpassed for beauty and gentility, while its citizens are progressive and sufficiently blessed with this world's goods to indulge all their reasonable tastes for the novel and the strange. With all these signs in its favour it is not surprising that we should find many new companies preparing to enter the field and a very lively interest among nearly all classes in the coming means of locomotion.

We do not suppose that British manufacturers will exhibit, as the time is too short for one thing, and it is not worth their while to do so for another. In this, as in so many other branches of manufacture, they are excluded from participation by the operation of a peculiarly hostile tariff which effectually shuts out our goods.

According to the Paris correspondent of the *Daily Telegraph* the final examination for the newly-created appointment of Inspector of Moto-Car Traffic in Paris took place on the 6th inst. There were some half-dozen competitors eager to be nominated to this responsible post. The successful candidate now bears, therefore, the official title of Inspector of the Traffic of Vehicles propelled by Mechanical Motors. This newly-appointed servant of the Prefecture of Police—whose post, considering the extraordinary popularity of the moto-car in Paris, is not at all likely to prove a sinecure—will be in receipt of an annual salary of £120, with an allowance of £20 yearly for travelling expenses. The inspector will keep an eye on obstreperous and law-breaking moto-drivers in this city. He will also be called upon to assist the engineers of the Government Corps of the Mines in submitting to a stiff examination candidates who are desirous of obtaining the certificate of *chauffeur* which confers the legal right to drive a moto-car in Paris. The new official's duties will likewise include inspecting all vehicles propelled by mechanical means, and certifying that the said vehicles may safely be put into use on the public highways. We may add that the successful candidate was M. Hommen, who is a professional engineer of considerable standing and reputation.

CORRESPONDENCE.

CELLULOID FOR CYCLE GEAR CASES.

To the Editor of The Automotor.

Sir,—I am advised to have a celluloid gear case for my cycle. On mentioning the matter to a friend he said celluloid was a most dangerous substance to have near one's person. What is celluloid; and is it dangerous? An answer will greatly oblige.—Yours truly,

Wimbledon, S.W. Jos. Finney.

[Celluloid is a compound of nitrocellulose, camphor, and water. It is a hornlike transparent substance, slightly yellow, its sp. gr. being 1·25 to 1·45. It is readily inflammable, being, in fact, somewhat akin to cordite. Such substances are distinctly dangerous. —Ed.]

THE CONSUMPTION OF PETROL.

To the Editor of The Automotor.

Sir,—In the paper dated July 15th, at p. 406, I find that a Daimler motor ran 52 miles on 2 gallons and 6 pints of petrol at a cost of about 1*s.* 9*d.* Is this correct? If so, where can the petrol be purchased at that price? Our machines, of which we have eight, consume quite double that amount of oil for a like distance. With apologies for troubling you.—Yours,

Falkirk District Motor Co. (Ltd.).

[The consumption is certainly low; we have not verified it by any independent test, and so it must be taken for what it is worth.—Ed.]

MILITARY MOTO-VEHICLES.

To the Editor of The Automotor.

Sir,—It may interest you to hear that I have completed a contract with Messrs. Vickers, Sons, and Maxim (Limited), for a sole licence for my motor war vehicles, and that I am now building for this firm two motor war carriages, one of which is a very light (3 cwt.) military railway inspection car, designed for operation in Egypt on the lines of the railway system. It is armour-plated, of 5 mm. Vickers's steel (small bullet proof), and accommodates two officers and one man. It is propelled by two of my small new petrol motors coupled together. The car has two definite speeds, viz., four and 16 miles per hour, the intermediate speeds being obtained by way of my new electric ignition timing gear. The car is equipped with a Maxim quick-firing gun, so mounted in its position that the direction of firing can be changed to any required position. It is entirely self-contained and automatic in its action.

The other vehicle is an armoured motor war-car, designed to run on ordinary roads, and even on rough surfaces, without rails. It is propelled by a 14 H.P. Daimler motor, and has four different speeds, the maximum being about 16 miles per hour, and this car can be run in either direction at the same speed. Two 8 mm. calibre Maxim guns are mounted in revolving turrets, in such a way that any angle of fire can be obtained. The armour is carried to a height of 6 feet above the axles and completely encircles the vehicle like a kind of crinoline or petticoat round the whole of the vehicle, and suspended from the main framing by independent springs, thus avoiding any tendency to jar, and is connected with the under frame by means of lateral stays designed to adjust themselves to the swing of the armour. The front and rear points of the frame are strengthened so as to form rams, and can be utilised in cutting a way through crowds. On the top of the armour half embedded rollers of steel are placed, which revolve freely on their spindles, so as to make it difficult for an opponent to board the car. The bottom of the steel armour plates are provided with a belt projecting about an inch, sharpened in case of war, so that the mere passage of the car would inflict heavy wounds on the assailants. This belt may also be insulated and connected to the electric current supplied off the main engine, and thus transmit shocks to those endeavouring to mount the car.

These war-cars will be introduced under the name of "Simms's Motor War-Car." The car will carry, in addition, a military searchlight (Suez Canal Type). The extreme dimensions are—length, 26 feet; beam, 8 feet; total weight, 3 tons.

Large space for ammunition, stores, &c., is provided, and accommodation for three to six men. The car is also arranged to serve as a tractor, if necessary, for hauling ammunition, war stores, or guns, or for the laying of field wires, or for ambulance services.

These carriages are now in the course of construction, and I shall be pleased to invite you to the trial trips in about three or four months' time.—I am, Sir, yours faithfully,

Amberley House, FREDERICK R. SIMMS.
12, Norfolk Street, Strand, W.C.

PARSONS'S STEAM TURBINE.

To the Editor of THE AUTOMOTOR.

SIR,—I am anxious to know whether the new steam apparatus used by Mr. Parsons for the "Turbinia" is likely to be used for moto-cars? A description is given in *Pearson's Magazine* for August, the vessel being propelled at the rate of 40 miles per hour.—Yours, &c., W. L.

[If you will read literature of the kind referred to you must not expect accurate technical information. Had you perused THE AUTOMOTOR regularly your knowledge of motors would be, or rather should be, sound, and you would have learnt that the Parsons's steam motor is in its present form a uni-direction motor. This, however, would not prevent its use for moto-vehicles. The objection to its use for this purpose is its excessively high speed of revolution.—ED.]

STEAM-POWER *v.* HORSE-POWER.

To the Editor of THE AUTOMOTOR.

SIR,—I notice that at the recent meeting of the London General Omnibus Company the chairman is reported to have said that steam-power could not be made to compete successfully with horse-power. Is this correct, because, if so, the repeated statements in THE AUTOMOTOR must be wholly incorrect? You, Sir, have always maintained that steam is more economical than horse-power. Either you or the chairman of the L.G.O.C. are wrong. I shall be curious to see your reply.—Yours truly,

A SHAREHOLDER IN THE LONDON GENERAL OMNIBUS COMPANY.

[We have no hesitation in saying, and we are prepared to substantiate our statement, that the assertion said to be made by the chairman of the L.G.O.C. is wholly incorrect. It is a matter of mathematical demonstration, corroborated by the practical experience that has been gained in France, that under similar conditions steam omnibuses can be worked cheaper than can horse-drawn ones. We trust that the shareholders in the London omnibus companies will apply to us for figures and facts, and we shall be glad to see the question fought out.—ED.]

FOUR OR SIX WHEELS?

To the Editor of THE AUTOMOTOR.

SIR,—In reply to Mr. Geo. Coombs's remarks on a previous communication of my own, I should like, with your permission, to say a word as to "trailing steerers." Surely the connection requisite to enable them to turn with the front steerers through an equal angle, but in an opposite direction, would not tax the ingenuity of even a practical engineer for very long; a jointed rod or two would soon settle the matter.

As regards locomotive practice, a central driving axle with supporting axles at either end is a not unknown type, and even the substitution of a bogie truck for a rigid axle does not affect the principle involved.

Again, a modern long bogie carriage (why should it not have a central supporting axle or two?) hints at fore-and-aft steering as a possible and perhaps not unreasonable design for common roads.

In conclusion, to limit a heavy moto-vehicle to four wheels seems to me rather like designing a two-wheeled omnibus because a hansom cab is found a convenient vehicle for two.—I am, yours faithfully,

ALFRED J. ALLEN.

London Institution, E.C., *September 1st.*

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL" by HERBERT HADDAN and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

Specifications Published.

THE following is a List of Specifications recently published, and obtainable at the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform charge of 8*d.* per copy. Owing to the enormous pressure upon our columns it has been found impossible to deal in any other form with the accumulation of patents now being taken out in connection with automobilism. As far as possible, a selection for special mention is made by the Editor from the more prominent inventions:—

Applied for during 1897.

16,380. C. RICCI, 47, Campana Road, Fulham, S.W. Ignition apparatus.
16,705. C. E. CALLOCH, 31, Boul. Henri IV, Paris. Moto-car.
16,715. E. H. HODGKINSON, 8, Lancaster Gate, London. Velocipedes and automotor carriages.
16,724. H. M. BIGWOOD, 131, Penn Road, Wolverhampton. Driving chains and chain wheels.
16,729. A. G. NEW, 8 and 10, Bridge Street, Westminster, S.W. Heavy oil engines.
17,084. R. C. SAYER, 11, Clyde Road, Redland, Bristol. Speed regulator.
18,865. The Hon. R. T. D. BROUGHAM and W. C. BERSEY, Juxon Street, Lambeth. Safety device for use in connection with carriages propelled by electricity.
19,069. C. JOST, 13, Hornby Row, Bombay, India. Fluid pressure motors.
20,801. J. EDMONDSON and J. W. DAWSON, Albert Electrical Works, Hey Street, Bradford. Starting apparatus.
20,845. A. MULLER, 31A, Luisenstrasse, Berlin. Accumulators.
14,649. X. DE LA CROIX, 117, Rue Froissard, Brussels. Motocycles.
20,455. P. JENSEN (C. and A. White, Baltimore, U.S.A.). Electric igniter.
21,823. C. TENNETT, and A. J. RILEY, 180A, Leeds Road, Bradford. Compound steam motors.
21,329. E. K. DUTTON, Arden, Cornwall Road, Harrogate, Yorks. Oil, gas, and analogous motors.
22,972. H. H. LEIGH (B. J. X. Gosseliu, 22, Boul. Poissonniere, Paris, France). Fluid pressure motors.
17,379. T. HEWETT, 6, Jeffrey's Square, St. Mary Axe, London. Chain gearing.
22,339. O. C. IMMISCH, 102, Tollington Park, London, N. Electric switch.

23,332. E. A. PARIS, 33, Chestnut Road, West Norwood, London. Secondary battery plates or electrodes.
30,365. G. DORE and H. I. BORUSSON, 15, Grand Rue, St. Maurice, France. Driving mechanism.
18,953. R. H. RIDOUT, Parkstone, Sunbury. Fluid pressure motors.
21,434. G. WEBB, Ganarew, near Monmouth, Hereford. Ball bearings.
21,651. W. H. BARKER, 37, Haverstock Hill, London. Driving mechanism.
22,386. J. KENNEDY, 25, Elmbank Street, Glasgow. Variable speed gearing.
23,528. Major H. C. L. HOLDEN, Royal Arsenal, Woolwich. Controlling gear.
18,531. H. J. LAWSON, 40, Holborn Viaduct, London. Motor road vehicles.
18,796. W. M. MCDOUGALL, 43, Sussex Avenue, East Orange, N.J., U.S.A. Storage batteries.
21,257. T. H. NEWCOMB, Addlestone Ironworks, Addlestone, Surrey. Brakes.
22,200. F. BILLING and others, Livery Street, Birmingham. Tool for forming grooves in the junctions of moto-car frames.
23,067. F. WOODCOCK, 5, Marshfield Place, West Bowling, Bradford. Pitch chains.

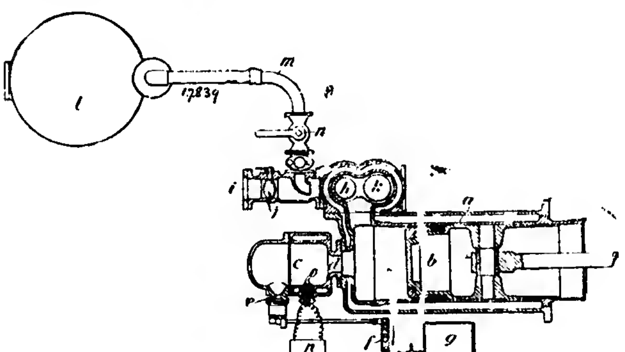
10,613. G. WESTINGHOUSE and E. RUUD, Pittsburg, Allegheny, Penn., U.S.A. Internal combustion engines.
10,911. A. J. BOULT, 111, Hatton Garden. Burners.
6,232. G. STRUCK, 18, Buckingham Street, Strand. Starting devices.

17,839. Explosion Engines. W. Hornsby and R. Edwards, Spittlegate Iron Works, Grantham, Lincoln. July 29th, 1897.

Relates to improvements in explosion engines of the kind forming the subject of letters patent Nos. 7,146 of 1890, 15,994 of 1890, 3,909 of 1892, and 6,933 of 1896, wherein to start the engine the vaporiser has to be heated.



a is the working cylinder, *b* the piston working therein, *c* the vaporiser in open communication with the cylinder, *a*, through the contracted neck, *d*, *e* the inlet for the liquid hydrocarbon in the vaporiser, *c*, *f* the pump for introducing the said liquid hydrocarbon from the tank, *g*, *h* the air inlet valve for admitting air through the passage, *i*, which passage is provided with a valve, *j*, for regulating the supply of air, and *k* the exhaust valve, all of which parts are arranged substantially in the manner described in the specifications before referred to and therefore require no further description herein.

l is a carburetter of any ordinary or suitable construction which has an air inlet opening and is also connected by a pipe, *m*, with the usual air passage, *i*, of the engine in such a manner that when the valve, *j*, in the said air passage is wholly or partially closed, air will be drawn through the carburetter and the pipe, *m*, into the cylinder, *a*, past the valve, *h*, on the outstroke of the piston, *b*, and will on the return stroke of the piston, *b*, when the valve, *h*, is closed be forced through the contracted neck, *d*, into the usual vaporiser, *c*.

n is a cock placed in the pipe, *m*, for controlling the passage of the carburetted air through the pipe, *m*.

o, *o* are the electric terminals of an igniter which are placed in connection with a source of electricity, for instance, with a battery, *p*, the said terminals being arranged in the usual manner so that the current will spark between them. The circuit of the battery, *p*, contains a contact maker which is controlled by the movements of the engine in such a manner that the circuit will be closed at the proper time when the piston is at the end of its instroke to ignite the charge which has been forced into the vaporiser or combustion chamber, *c*.

q is a cock which is arranged between the oil reservoir, *g*, and the pump, *f*, for shutting off the supply of oil to the said pump.

In starting an engine the cock, *q*, is closed and the cock, *n*, is opened so that on the outstroke of the piston which is produced in any suitable manner, for instance, by manual power, a charge of carburetted air will be drawn into the cylinder, *a*, which charge on the backward stroke will be forced into the combustion chamber, *c*. When this has been effected the said charge will be ignited by the electric spark between the terminals, *o*, *o*, whereupon the piston, *b*, will be forced outwards by the explosion and thereafter continue to work by the explosion of the successive charges drawn through the pipe, *m*. When the vaporiser, *c*, has become sufficiently hot to vaporise and ignite the usual oil with which the engine is intended to work, the cock, *n*, is closed and the cock, *q*, is opened so that the usual oil will be injected into the vaporiser by the pump, *f*, and air will enter the cylinder through the passage, *i*, the valve, *j*, having been previously opened to the desired extent.

10,579. Brake Gear for Railway Wagons, &c. Edward Brown, Goosehill, near Normanton, Yorkshire. April 28th, 1897.

The gear consists of a shaft placed across the wagon or similar vehicle, capable of being rotated by a handle or hand-wheel from either side of the vehicle; on this shaft is fixed near one end—or both ends in case of the brakes being required to act on four wheels—a bevel or mitre wheel, gearing into a suitable wheel or wheels fixed on a longitudinal shaft or shafts, the said shaft or shafts being carried by castings firmly fixed to the sole bar of the vehicle, and provided with bearings or journals at right angles to each other, the said longitudinal shafts having a thread cut at the opposite end, engaging a nut, circular in section, held loosely in a lever, which is solid with and forms part of a rocking lever, to which push rods are attached from it to the brake blocks, the said rocking lever being supported by, and free to rock on, a short shaft firmly fixed and carried by hangers from the sole bar of the wagon or similar vehicle.

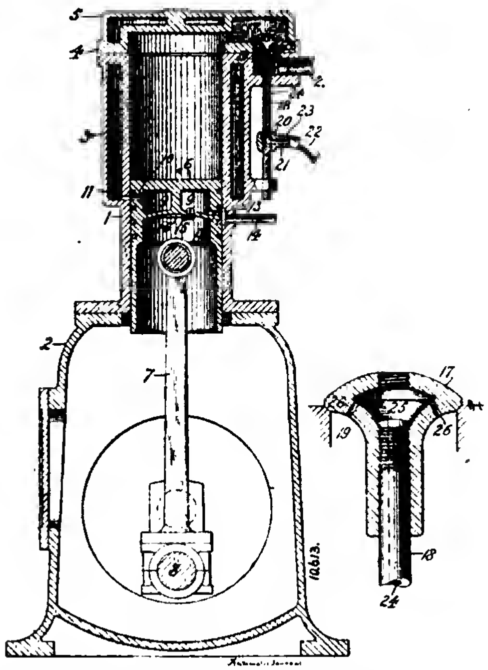
10,613. Internal Combustion Engines. G. Westinghouse and E. Ruud, Pittsburg, Pennsylvania, U.S.A. May 9th, 1898.

The object is to provide an improvement in internal combustion engines; and to this end it consists in means for cooling certain movable parts of the engine, and in certain combinations and features of construction.

The cylinder, 1, of the engine is mounted on a crank case, 2, and is surrounded on a part of its length by a jacket, 3, within which a cooling medium is circulated for the purpose of preventing injurious over-heating of the cylinder. The cylinder head, 4, is provided with a jacket, 5, and the space through which the cooling medium is passed around the cylinder is, preferably, in communication with the space enclosed by the jacket or cylinder head.

The main piston, 6, is connected by a connecting rod, 7, with the crank, 8, on the main shaft, and in the upper portion of the piston is formed a chamber, 9, which is provided with a port or passage, 10, so located that it is adapted to register with a passage, 11, in the wall of the cylinder, when the piston is at or near the lower end of its stroke. The passage, 11, communicates with the interior of the jacket, 3, and when the piston is at or near the lower end of its stroke, the chamber, 9, is in communication with the interior of the jacket, 3. A passage, 12, through the wall of the piston is adapted to connect the chamber, 9, with a port, or cavity, 13, when the piston is at or near the lower extremity of its stroke, and a pipe, or passage, 14, leads from the cavity, 13.

When a cooling fluid is supplied to the jacket around the cylinder, and the piston, 6, moves into position to connect the ports, or passages, 10 and 11, a portion of the cooling fluid will pass through those passages into the chamber, 9, in the piston, 6, and at the same time, and during the time that the passage, 12, is in communication with the cavity, 13, fluid will flow from the chamber, 9, through the passage, 12, and cavity, 13, and be discharged through the pipe, or passage, 14.



When the piston moves from the position which it occupies, and during its upward and downward stroke, the flow through passage, 11, from the jacket, and the flow through the passage, 12, from the chamber, 9, will be cut off, and chamber, 9, will be kept charged with fluid during the upward and downward stroke of the piston.

When the piston approaches the end of its downward stroke, the passage, 12, will register with the cavity, 13, before the passage, 10, registers with the passage, 11, and there will be little or no resistance to the passage of the cooling fluid into the chamber, 9, through the passages, 11 and 10.

If water or other liquid be employed as the cooling fluid, it may flow to and through the pipe, 14, by the action of gravity only, or it may, if preferred, be forced through and out of the piston under pressure, no matter what the fluid may be.

In order to avoid explosion by pressure generated from the fluid within the piston, we may provide a safety or relief valve, 15, for controlling a passage leading from the chamber, 9, into the open ended trunk of the piston, and through which the pressure may be relieved, and fluid discharged into the crank case. The valve, 15, is normally hold to its seat by spring, 16.

In order that the pipe, 14, and cavity, 13, may be quickly and surely cleared by water before the return of the piston, it is preferred that the lower end of the piston should pass above the cavity, 13, or at least partly uncover it, when the piston moves to the upper end of its stroke, so as to permit water to drain therefrom into the crank case.

The exhaust valve, 17, is provided with a downwardly extending stem, 18, which may be operated by any preferred means so as to open and close the exhaust passage, 19, at the proper times, and the valve and stem are made hollow and provided with means for circulating water or other cooling fluid therethrough.

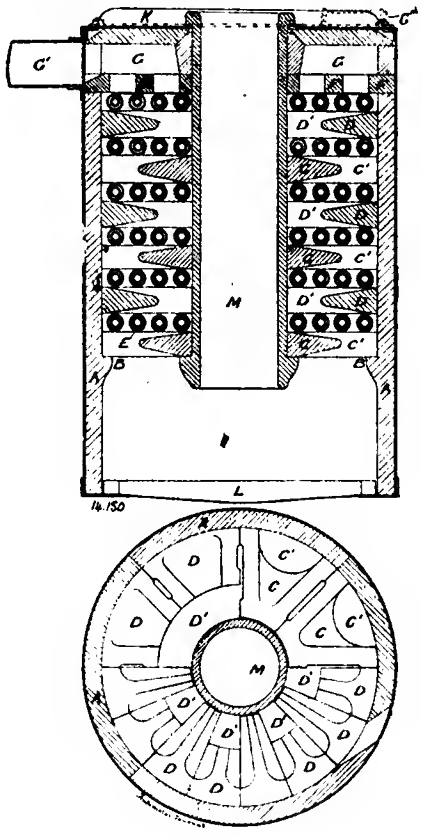
A collar, 20, is clamped or otherwise rigidly secured on the stem, 18, and a nipple, 21, formed on the collar, is provided with a passage, 23, which connects at one end with the passage, 24, formed on the stem, 18, and which at its other end opens into the flexible pipe or hose, 22, which is secured to the nipple, 21. The flexible pipe or hose, 22, may be connected with any pipe, passage, or vessel from which the cooling fluid is to be supplied, and it should be of such ength and flexibility as to permit the necessary reciprocating movement of the stem, 18, by which the valve is opened and closed. The cooling fluid passes through the pipe, 22, passages, 23 and 24, and fills the chamber, 25, in the valve, 17, from which it flows through the passages, 26, into the exhaust passage, 19, and is discharged with the burnt gases through the exhaust pipe, 27. Modifications are described and shown.

14,150. Steam Generators. W. W. Beaumont, Outer Temple, 222, Strand, London; and H. P. Holt, 22, Chancery Lane, London. June 10th 1897.

Relates to steam generators chiefly of the type described in the Specification of the Patent No. 5,505 of 1897, and consists in the arrangement of the tubular or other heating surfaces, or water and steam enclosing envelopes and their connections and attachments, and also in the methods of supporting these tubes or envelopes by, and the formation of, the generator casing lining and heat storing blocks forming flues or passages for the products of combustion.

The generator casing is lined with the vertical segmental pieces, A, on the lower inside of which is formed a projection for supporting the discs, C and D, and the generator tubes, E, and leaving the spaces, C^1 and D^1, for the passage of the gases which finally find their way through perforated segmental discs, F, into the space, G, surrounded by blocks of refractory material, and from which the gases pass out to a chimney, as at G^1, or as indicated by dotted lines at G^{11}. The blocks, D, are shown in three forms; the one form as shown in the lower part of the drawing consists of alternate long and short blocks, leaving alternate flue spaces, D^1. In the upper part of the same drawing the blocks, D, are formed so as to leave a continuous or unbroken annular flue space, D^1; in the right hand upper part of the same drawing are shown the segmental disc-forming blocks, C, which leave the flue spaces, C^1, near the casing instead of towards the centre of the generator.

In another form of generator the blocks, C and D, are similar to those already described, but are in some cases carried into the centre, where they take the place of the central tube.



Grate bars for solid fuel are shown, and the fuel may be fed in by the tube, M, which would be fitted with a cover not shown; a fire door in the lower part of the casing would be provided in the ordinary way for access to the fire or for clinkering.

Other modifications and details are also described.
